PRINTED IN THE UNITED STATES OF AMERICA

PREFACE

The second edition of "Van Nostrand's Scientific Encyclopedia," follows generally the premise of the original volume. The book encompasses the basic sciences and the applied fields of science and engineering. There have been added to this edition new sections on Electronics and Radio, Metallurgy, Meteorology, Photography and Statistics. The sections on Aeronautics, Engineering—Chemical, Civil, Mechanical, and Electrical—and Navigation have been expanded considerably. The entire book now takes into account the broad advances of science that have occurred in Aeronautics, Astronomy, Botany, Chemical Engineering, Chemistry, Civil Engineering, Electrical Engineering, Electronics and Radio, Geology, Mathematics, Mechanical Engineering, Medicine, Metallurgy, Meteorology, Mineralogy, Navigation, Photography, Physics, Statistics, and Zoology—twenty sections.

The responsibility for each science has been left largely in the hands of a single author in order to attain a unity impossible when many men contribute. However, although the responsibility rested largely in the one scientist of note, a number of men in each field have worked with the author, and a still larger group have consulted in an advisory capacity with the authors and publishers.

In this Encyclopedia over eleven thousand terms of scientific interest are arranged alphabetically, and an extensive system of cross-indexing has been developed to enable the reader to find all the facts that bear directly on each included topic. By this system, terms explained in this book are printed in bold face (black face) type wherever they are used significantly in the course of the articles on other terms. This practice makes it possible to turn readily to every article that has a bearing on the particular topic in which the reader is interested, as well as to obtain all supplementary information relative to any particular subject. Wherever bold face type appears within an article, the word or term appearing in this type is described in its alphabetical position. The user can gain a very comprehensive knowledge of each term if these references are consulted.

Naturally there are limits in the compiling of any one-volume book. These limits necessarily restrict the length of the article and the size of the illustration. However, the comprehensiveness of the book is noteworthy both in the scope of the terms covered and the breadth of the treatment in the individual article. The meticulous care of the authors, their advisers and their helpers, together with their systematic cross-referencing, have contributed in great measure to the inclusion of so much material within the covers of one book.

A feature of this Encyclopedia is the progressive development of the discussion of each topic, beginning with a simple definition expressed in the plainest terms and progressing to a final reflection of the more detailed scientific aspects of the topic treated. Articles dealing with simple concepts are, of course, treated in simple terms throughout the Encyclopedia, but those of a highly technical nature may be of value both to the inquiring layman and to the trained technician by a selection of their reading from the earlier or later portions of such an article.

The authors and the publishers will appreciate the indulgence of the reader for omissions. The exercise of judgment in the selection of material was unavoidable, and it was necessary to maintain a limit of difficulty beyond which it was impractical to go in attempting to cover so broad a field within the physical confines of one useful volume.

October, 1946

ACKNOWLEDGMENTS

Special articles appear under the authorship of individuals outside the consulting and contributing editor group. Acknowledgment is sincerely offered here to the following men and organizations who have prepared material or who have served in an advisory capacity: The Aluminum Company of America; The American Society for Metals; R. E. Barnard, R. S. Burns, M. E. Carruthers, G. H. Cole, and C. R. Taylor of the American Rolling Mills Company; J. S. Smart, Jr., of the American Smelting and Refining Company; Bakelite Corporation; E. B. Ferrell, Bell Telephone Laboratories, Inc.; J. A. Fizzell, Illinois Testing Laboratories, Inc.; Dr. Alexander Klemin; Polaroid Corporation; Dr. H. F. Olson, Radio Corporation of America; Dr. J. K. Robertson, Queen's University, Ontario; E. W. Saunders, University of Virginia; G. A. Roberts, Vanadium Alloy Steel Company.

Van Nostrand's Scientific Encyclopedia

A

A SUPPLY. The source of the heating current for the cathode of an electronic tube. In the early days of radio the various voltages needed to operate a receiver were obtained from batteries, called A, B and C batteries, supplying the filament, plate and grid voltages respectively. These letter designations have carried over to the present-day sources, although the voltages are usually obtained now from an a-c source, either directly as in the case of the A supply or indirectly for B and C voltages. (See **Amplifiers** and **Radio Receivers.**) (L.R.Q.)

AA. An Hawaiian term introduced into geological nomenclature by C. E. Dutton, in 1883, and signifying the jagged, scoriaceous, blocky and exceedingly rough surface of some **basic** lava flows. (R.M.F.)

AARD-VARK. Mammalia, Tubulidentata. *Orycteropus.* African animals of peculiar form, including an Ethiopian and a South-African species. All are ant-eaters, feeding exclusively on ants and termites. The southern species has been called the ant-bear. (A.W.L.)

AARITE. Niccolite.

AARD WOLF. Mammalia, Carnivora. An African species, *Proteles cristatus,* superficially like the striped hyena. (A.W.L.)

AASVOGEL. South-African **vultures.** The name was applied by the Dutch colonists and means carrion-bird (A.W.L.)

ABACA. The **sclerenchyma** bundles from the sheating leaf bases of *Musa textilis* (**Manila hemp**), a plant closely resembling the edible banana plant. These bundles are stripped by hand, after which they are cleaned by drawing over a rough knife. The fiber bundles are now whitish and lustrous, and from six to twelve feet long Being coarse, extremely strong and capable of resisting tension, they are much used in the manufacture of ropes and cables. Since the fibers swell only slightly when wet, they are particularly suited for rope which will be used in water. Waste manila fibers from rope manufacture and other sources are used in the making of a very tough grade of **paper,** known as manila paper. The fibers may be obtained from both wild and cultivated plants, the latter yielding a product of better grade. The cultivated plants, propagated by seeds, by cuttings of the thick *rhizomes* or by suckers, are ready for harvest at the end of three years, after which a crop may be expected approximately every three years. (R.M.W.)

ABALONE. Mollusca, Gasteropoda. *Haliotis.* Marine species, mostly of the Pacific and Indian Oceans. The single broad shallow shell has a richly colored iridescent inner surface and is an important source of mother-of-pearl and blister pearls for costume jewelry. The flesh is palatable. It is eaten on our west coast, but much larger quantities are dried in California for shipment to the Orient. (A.W.L.)

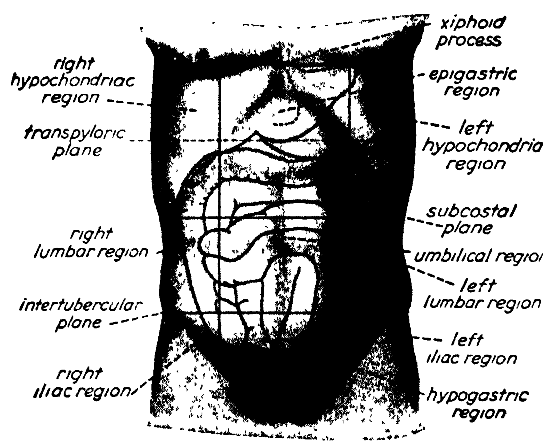
ABAMPERE. The abampere, formerly called the "electromagnetic unit current," is the fundamental unit of the **c.g.s.** (centimeter-gram-second) electromagnetic **system of electrical units.** If a current of this magnitude flows in a circular loop of 1 cm. radius in a vacuum, the resulting magnetic field has an intensity, at the center of the circle, of 2π **oersteds;** which is the same as 1 oersted per unit length of wire. An equivalent statement is that if a current of 1 abampere flows in a straight wire across a magnetic field of 1 oersted intensity, at right angles to the magnetic intensity, the resulting lateral thrust, or "electric motor effect," is equal to 1 dyne for each centimeter of length of the wire. The (absolute) **ampere** is defined as $\frac{1}{10}$ of the abampere. (L.D.W.)

ABCOULOMB. Electric and Magnetic Units.

ABDOMEN. The abdomen is the posterior division of the body in many **arthropods.** It is the *posterior* portion of the trunk in **vertebrates.** In the vertebrates this region of the body contains most of the alimentary tract, the excretory system, and the reproductive organs. It contains part of the **coelom** and in mammals is separated from the thorax by the **diaphragm.**

The abdominal cavity of the human body is subdivided into the abdomen proper and the pelvic cavity.

The walls of the abdominal cavity are lined with a smooth membrane called the **peritoneum,** which also provides partial or complete covering for the organs within the cavity.



Planes of subdivision of the abdominal cavity and outline tracing of the liver, stomach, and intestine in relation to the anterior abdominal wall.
The oblique position of the stomach and the high position of the transverse colon are largely due to the fact that the subject was fixed in the horizontal position.
(*Cunningham, Textbook of Anatomy, Oxford Press*)

The abdomen proper is bounded above by the diaphragm; below it is continuous with the pelvic cavity; posteriorly it is bounded by the spinal column, and the back muscles; and on each side by muscles and the lower portion of the ribs. In front, the abdominal wall is made up of layers of **fascia** and muscles. The surface of the abdomen is divided into sections. The mid-section above the navel between the angle of the ribs is known as the epigastric region; that portion around the navel, as the umbilical; below the navel and above the pubic bone, as the hypogastric region. It is further divided

into right and left upper quadrants on each side above the navel, and right and left lower quadrants on each side below the navel. The lumbar region extends on either side of the navel posteriorly and laterally.

The principal organs of the abdominal cavity are the **stomach, duodenum, jejunum, ileum,** and **colon** or large intestine, the liver, **gall bladder** and biliary system, the **spleen, pancreas** and their blood and lymphatic vessels, **lymph glands,** and **nerves.**

The pelvic portion of the abdomen contains the urinary **bladder, uterus, Fallopian tubes,** and **ovaries** in the female, the sigmoid colon and **rectum,** and a portion of the small intestine. (A.W.L., R.S.M.)

ABERRATION OF LENSES. **Chromatic Aberration; Spherical Aberration.**

ABERRATION OF LIGHT. The apparent change of position of an object, due to the speed of motion of the observer, is known as the aberration of light. Care must be taken not to confuse this effect with that of **parallax.**

If a **telescope,** assumed to be stationary, is pointed at a source of light, the light which enters the object glass centrally and in the direction of the optic axis will pass through the telescope along that axis and emerge through the center of the eyepiece. If the telescope is in motion relative to the source, in any direction other than parallel to the optic axis, the light which enters centrally will emerge off the center of the eyepiece. If this light is to emerge centrally the telescope must be tilted forward in the plane containing the direction of motion of the instrument and the source. The amount of tilt will depend on the direction of the source and the ratio of the speed of the telescope to the speed of light.

This aberrational effect was first announced by Bradley in 1726. He noticed that stars had apparent periodic motions with a period of one **sidereal year,** and that the character of the apparent motion depended upon the **celestial latitude** of the star. He correctly interpreted the effect as due to the motion of the earth about the sun. Statistical discussions of the observations of a large number of stars have shown that the maximum value of this aberration due to the earth's **orbital motion** is 20″.47. This is known as the "aberration angle" or as the "constant of aberration." An aberrational effect of about 0″.3, at maximum, is observed due to the rotation of the earth on its axis.

In 1871, Airy made a series of observations for determination of the aberration constant using a telescope filled with water. Since the value of the **index of refraction** of water is about ¾, Airy expected that the value of the aberration would be 27″.3 when using the water-filled tube. He found, however, that the value was 20″.5 no matter what substance was placed in the telescope. The result of this so-called "Airy's Experiment" caused much discussion, but was eventually explained on the basis of the **Michelson-Morley experiment** and the **theory of relativity.**

All observations, in which the positions of the stars are involved, must be corrected for aberration of light if the results are to be accurate to within 20″. Both the motion of the earth about the sun and the rotation of the earth must be considered. The magnitude of the correction depends upon the **celestial coordinates** of the star, the position of the observer on the earth, and the date and time of observation. (W.K.G.)

ABFARAD. **Electric and Magnetic Units.**

ABHENRY. **Electric and Magnetic Units.**

ABIOGENESIS. The origin of living matter or living organisms from non-living material.

The ancients believed that living things, such as insects and mice, sprang from decaying organic matter or even from mud in situations where they were sometimes seen in large numbers. Careful experiments finally showed that such highly organized creatures were produced only by others like themselves but the discovery of microorganisms again raised the question. In the experiments conducted by Pasteur and other scientists, it was at last proved that thoroughly sterilized materials gave rise to no living things unless they were later contaminated. Modern biology admits the possibility that an exceedingly simple type of living substance may arise from nonliving materials but recognizes that living things as we know them are too complex to develop abruptly in this way. Even the origin of simple living substance has not actually been demonstrated. (A.W.L.)

ABLATION. From the Latin *ab* and *latio,* carried from, refers to the wasting away of the surfaces of rocks or **glaciers,** but principally used in the latter connection. Ablation deposits are the masses of **detritus** left after surface melting of glacial ice. (E.S.C.S., R.M.F.)

ABOHM. **Electric and Magnetic Units; Ohm.**

ABORAL OR APICAL SYSTEM. Part of the nervous system of the **echinoderms.** Unlike most nervous tissue it is developed from the middle germ layer. (A.W.L.)

ABORT. This term has two common meanings in medicine: 1. To check a disease or a condition during its early stages. 2. To expel the **fetus** during the first 4 or 5 months of pregnancy. (D.M.H.)

ABORTION. The expulsion of the **fetus** during the first half of **pregnancy,** which is always incompatible with the life of the fetus. Various descriptive terms are used to indicate the type of abortion as (1) accidental, (2) artificial or induced, i.e., intentional, (3) criminal, that is, induced illegally, (4) habitual, or where it occurs repeatedly with successive pregnancies in the same person, (5) incomplete, or where only a portion of the products of conception are expelled, (6) therapeutic, an abortion induced by a doctor as a protection to the life or health of the mother. Therapeutic abortions are commonly done when the mother has advanced **tuberculosis, kidney** or **heart disease.** (7) Threatened abortion, that is, the appearance of hemorrhage or labor pains early in pregnancy, may or may not develop into an actual abortion. (R.S.M.)

ABRASION. All metallic and non-metallic surfaces, no matter how smooth, consist of minute serrations and ridges which induce a cutting or tearing action when two surfaces in contact move with respect to each other. This wearing of the surfaces is termed abrasion. Undesirable abrasion may occur in bearings and other machine elements, but abrasion is also adapted to surface finishing and machining, where the material is too hard to be cut by other means, or where precision is a primary requisite. (H.C.H.)

ABRASIVES. Grinding, cutting, drilling, and polishing of various materials are often done with a wheel, sheet, or blast of abrasive, so-called, somewhat harder than the material treated. Accordingly, in the selection of an abrasive, the size of the individual grains and their specific hardnesses become important factors which determine the appearance of the finished surface or edge. The selected grains are bonded to a surface, such as sandpaper or emery paper, or formed into special shapes, especially wheels of various widths and diameters, or spotted on the face of drills as in sinking oilwells.

Many naturally occurring materials are used for this purpose, and for the harder abrasives specially manufactured materials are commonly utilized. The natural abrasives most used are sand, quartz, emery, diatomite, tripoli, pumice, and diamonds.

Sand, sandstone, quartzite and quartz, flint, and garnet are most used in sand-blasting of metals, in sawing-stones, grindstones, pulpstones, whetstones, in the grinding of ores in mills, and as sheets on paper or cloth. Emery and corundum are similarly used, practically all being imported as crude material and processed in this country.

Diatomite is used principally in polishes, but also as filter aid due to its high porosity, and as filler in special cases such as in plastics. It is highly resistant to heat, has low absorptive power for moisture, is chemically inert, has excellent electrical properties, and produces a good surface finish. It is stated that four leading brands of silver polishes contain 15 to 19% of diatomite as the sole abrasive. The principal states producing diatomite are California and Oregon. Tripoli is used for abrasive purposes, as an oilwell drilling mud, and also for foundry facing, and for filler in concrete. The production is centered around Newton County, Missouri, and adjacent Ottawa County, Oklahoma, and in Alexander County, southern Illinois. Pumice is used in cleansing and scouring mixtures and in hand soaps, and also for acoustic plaster and as an admixture for concrete.

Diamonds for abrasive purposes come from Brazil—these are called carbonados or black diamonds—and from the Union of South Africa—these are called bort. A beryllium-copper alloy is used successfully for cast-setting diamond core bits and reaming shells. These drilling bits are tough, strong, and hard, and the bond between the alloy and the diamonds is very close. Many small stones can be spaced over a comparatively small drill face.

Manufactured or "artificial" abrasives have made possible rapid working of very hard materials. Aluminum oxide glass ("Alundum") and silicon carbide crystals ("Carborundum") have proved outstandingly important. The total production manufactured for all uses, in 1941, in the United States, was aluminum oxide 150,000 short tons, and silicon carbide 45,000 short tons, with additional 85,000 short tons of metallic abrasives. Tungsten carbide has attracted much attention as a very hard abrasive It is typical of several metallic carbides, nitrides, and borides that have been suggested as abrasives Some information on this point is contained in the following table:

HARDNESS AND MELTING POINT OF VARIOUS CARBIDES, NITRIDES, AND BORIDES

> Greater than. Mohs' Values: Diamond 10, Corundum 9, Topaz 8, Quartz 7.

Metal	Carbides		Nitrides		Borides	
	Hardness (Mohs' value)	Melting Point (°C.)	Hardness (Mohs' value)	Melting Point (°C.)	Hardness (Mohs' value)	Melting Point (°C.)
Chromium	>7	1890			8	
Columbium		3500	>8		>9	
Molybdenum	7–9	2700			>9	
Tantalum	>9	3875	>8	3100	>9	
Titanium	>8	3150	>8	2950	>9	
Tungsten	>9	2850			>9	
Vanadium	>9	2830		2050	>9	
Zirconium	>8	3530	>8	2980	>9	3000

(R K.S.)

ABSAROKITE. A geologic term proposed by Iddings in 1805 for a **porphyritic basalt** containing **phenocrysts** of **olivine** and **augite** in a ground mass of smaller **labradorite crystals**. Type locality, Absaroka Rane, Yellowstone Park. (R.M.F.)

ABSCESS. A localized collection of pus usually formed in response to an infectious agent. **Staphylococci** and **streptococci** are the common bacteria producing abscesses, although any organism may do so.

Abscesses may be single or multiple, primary or metastatic (see **Metastasis**), and may involve any organ or tissue in the body. The wall of an abscess is made up of inflammatory tissue which acts as a barrier to the spread of infection; the abscess cavity contains **pus** which consists of white blood cells, debris of tissue destruction, and **bacteria**, living and dead.

The physical signs associated with a superficially situated abscess are those of **inflammation**, swelling, increased heat, redness and tenderness over the involved area. Treatment in uncomplicated cases is usually surgical incision and drainage at the proper time. Chemotherapy with **sulfonamides** and **penicillin** may be necessary. (D.M H)

ABSCISSA OF A POINT. **Rectangular Coordinates in a Plane.**

ABSCISSION. This term is applied to the process whereby leaves, leaflets, fruits or other plant parts become detached from the plant. Leaf abscission is a characteristic phenomenon of many species of woody dicots and is especially conspicuous during the autumn period of leaf fall. Three main stages can be distinguished in the usual process of leaf abscission. The first is the formation of an abscission layer which is typically a transverse zone of parenchymatous cells located at the base of the petiole. The cells of this layer may become differentiated weeks or even months before abscission actually occurs. The second step is the abscission process proper which occurs as a result of a dissolution of the middle lamellae of the cells of the abscission layer. This results in the leaf remaining attached to the stem only by the vascular elements which are soon broken by the pressure of wind or the pull of gravity and the leaf falls from the plant. In the final stage of the process the exposed cells of the leaf scar are rendered impervious to water by lignification and suberization of the walls (see **Lignin**; **Suberin**). Subsequently other layers of corky cells develop beneath the outer layer. These layers eventually become a part of the periderm of the stem. The broken xylem elements of the leaf scar become plugged with **gums** or **tyloses** and the phloem elements become compressed and sealed off.

In some kinds of plants an abscission layer is only imperfectly formed and in many others, especially herbaceous species, no abscission layer develops at the base of the petiole. In a few herbaceous species, of which coleus, begonia, and fuchsia are examples, an abscission layer develops. In the majority of herbaceous species, however, and in some woody species, there is no true abscission process. In such herbaceous plants most or

all of the leaves are retained until the death of the plant. In the woody plants falling in this category (example: shingle oak, *Quercus imbricaria*) the leaves are shed only by mechanical disruption from the plant. Abscission of the fruits of apple and doubtless of many other species occurs in much the same manner as abscission of leaves The abscission of apple fruits can be artificially retarded by spraying with certain **auxins.** (B.S.M.)

ABSINTHE. Artemisia.

ABSOLUTE HUMIDITY. The mass of water vapor in a specified volume. It can be expressed in any convenient units: ounces per cu. yd., grams per cu. meter Example: 22 grams per cu. meter. (See **Humidity.**) (P.E.K.)

ABSOLUTE MAGNITUDE. The apparent brightness of a star, or any other luminous object, depends both upon the intrinsic brightness of the object and also upon its distance from the observer. In the case of the stars the apparent brightness, expressed as **stellar magnitude,** may be determined by any one of the standard methods of stellar **photometry.** In case the distance of the star is known the intrinsic brightness may be immediately calculated. Conversely, if we have any method available for determining the intrinsic brightness of a star independently of a knowledge of the distance, this distance may be computed from the ratio between the apparent and intrinsic brightness.

The absolute magnitude of a star is the apparent brightness, expressed on the magnitude scale, that a star would have if it were situated at a distance of ten **parsecs** from the sun or, in other words, if the **stellar parallax** of the star were 1/10 of a second. Analytically, the absolute magnitude, M, of a star is connected with the apparent magnitude, mg, and the stellar parallax, π'', by:

$$M = mg + 5 + 5 \log \pi''.$$

On this scale we find the sun, with apparent magnitude -26.72 and parallax $206265''$, to have an absolute magnitude of 4.85. **Antares** with parallax $0''.009$ and apparent magnitude 1.22 is found to have an absolute magnitude of -4.0. On the basis of these absolute magnitudes and the defining relation of the magnitude scale, we find the brightness ratio of Antares to the sun to be 3470 or the star Antares is actually 3470 times as bright as the sun. (W.K.G.)

ABSOLUTE TEMPERATURE. Absolute Zero; Temperature Scales.

ABSOLUTE VALUE OF A REAL NUMBER. Number.

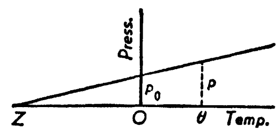
ABSOLUTE VARIABILITY. A measure of variability that is expressed in the unit of the **variable.** A measure of **relative variability** relates the absolute variability to an **average,** generally to the **mean.** (L.A.A.)

ABSOLUTE ZERO. A temperature at which bodies would possess no heat whatever. Prior to the discovery of the dynamic character of heat, no significance could be attached to a zero of temperature save that of a point arbitrarily chosen, such as the melting point of ice, from which temperatures might be reckoned both ways. But when it became known that heat is the kinetic energy of random molecular motion, it was at once possible to visualize, if not to realize, a condition of "absolute cold," merely by supposing the **molecules** of a substance to have come to rest relative to each other.

It was formerly customary to define the measure of **temperature** in such a way that a linear relation exists between the temperature θ and the pressure p of a gas (hydrogen) kept at constant volume; thus:

$$p = p_0 + a\theta \qquad (1)$$

in which p_0 is the pressure at the arbitrary zero of temperature. This relation is represented by the straight line in the accompanying figure. The slope of this line,



Relation between temperature and pressure of a gas at constant volume.

expressed by the constant a, corresponds to the change in pressure for each unit of temperature change (degree). Experiment shows that when the centigrade scale is used, this change is 0.0036626 of the pressure of the gas at the zero of that scale, viz., the melting point of ice; so that $a = 0.0036626$. (This is on condition that the pressure p_0 is 1000 mm.) Equation (1) accordingly may be written

$$p = p_0 + 0.0036626 p_0\theta = p_0(1 + 0.0036626\theta). \qquad (2)$$

Equation (2) now implies the possibility of causing the pressure to vanish altogether by reducing the temperature until the factor $1 + 0.0036626\theta = 0$; that is, until $\theta = -273.03°$ C. $= -459.45°$ F. (corresponding to Z in the figure). Since gas pressure depends upon the motion of molecules, it follows that, for the pressure to vanish, all such motion must cease. Hence we may suppose that the centigrade temperature $-273.03°$ C. is the absolute zero, so far as translational thermal energy is concerned. More recent studies employing the **Kelvin scale** of temperature give $-273.16°$ C. as absolute zero. There is reason to believe that a pressure would still exist in hydrogen even under these conditions. The lowest temperature so far experimentally attained is calculated to be within 0.005° of absolute zero. (See **Thermometry.**) (L.D.W.)

ABSORBENT COTTON. Absorbent cotton is prepared from the fibers of the **cotton plant.** These fibers are treated in such a way as to remove the natural waxy substances and the small amount of mineral matter present. Subsequent washing yields the product known commercially as absorbent cotton, which can absorb as much as eighteen times its own weight of water, and which has many commercial and medical uses. (R.M.W.)

ABSORPTION. This term has the widest significance in science and technology. In the organic world it denotes the process by which materials enter the living substance of which the organism is composed. Substances including food and oxygen are taken into special organs by ingestion and respiration but they must pass through the outer surface of the **cells** to become an integral part of the organism by absorption. The nature of the process is considered under **osmosis.**

The absorption of gases plays an important part in engineering. It is the frequent cause of **corrosion** by condensate (due to the high content of dissolved oxygen). Gaseous absorption is the basis of the absorption system of **refrigeration.** In this system a gas (or vapor) is absorbed in a suitable medium and is then separated by distillation, followed in some cases by liquefaction under pressure. The principles involved in the absorption of gases in liquids are treated in the article on **Solutions** and **Solubility,** and in the article on **Dissolving.** The adsorption of gases (as well as liquids and solids) is a related phenomenon that is treated in the article on **Adsorption.**

The quantity of heat absorbed by a substance is calculated from **specific heat** and **temperature.** The capacity of surface to absorb radiant heat is measured by its absorptivity (**Thermal Radiation**).

The absorption of mechanical energy by **dynamometers,** which convert the mechanical energy to heat or electrical forms, has lead to the use of the term "absorp-

tion dynamometers" to distinguish these machines. For the absorption of radiation see **Absorption Coefficient.** (F.T.M., A.W.L.)

ABSORPTION COEFFICIENT. A quantity used to express the rate at which a substance absorbs radiation passing through it. When light, x-rays, or other **electromagnetic radiation** enters a body of matter, it experiences in general two types of attenuation. Part of it is subjected to **scattering**, being reflected in all directions without essential change of character, while another portion is absorbed by being converted into other forms of energy. The scattered radiation may still be effective in the same ways as the original, but the absorbed portion ceases to exist as radiation or is re-emitted as secondary radiation. Strictly therefore we have to distinguish the true absorption coefficient from the scattering coefficient; but for practical purposes it is sometimes convenient to add them together as the total attenuation or extinction coefficient.

Accurate measurements upon radiation which has traversed various thicknesses of matter has established that any infinitely thin layer perpendicular to the direction of propagation cuts down the flux density by a fraction of its value proportional to the thickness of the layer, and that the flux density after having penetrated the medium to a distance x is

$$I = I_0 e^{-ax};$$

in which I_0 is the flux density just after entrance into the medium (i e., for $x = 0$). For true absorption, the constant a is the absorption coefficient (commonly designated by μ). For scattering, which obeys the same law, a is the scattering coefficient. And for the total attenuation, including both, it is the extinction coefficient, which is the sum of the absorption and the scattering coefficients.

Another way of expressing the absorbing effect of a substance is to specify the "half-value layer," which is that thickness of the substance which will reduce the flux density to ½ its original value, so that $I = \frac{1}{2}I_0$. This thickness is equal to $0.6931/a$. Thus if the absorption coefficient of copper for certain x-rays is 13.5 cm.$^{-1}$, the half-value layer for these rays is 0.0513 cm. thick. For many purposes it is convenient to use the mass absorption coefficient, which is the absorption coefficient of the substance divided by its density.

In general the absorption coefficient of a medium varies characteristically with the wavelength of the radiation, as illustrated by the absorption of x-rays in aluminum, tabulated below.

Wave-length (X-units) *	Absorption Coefficient (Cm.$^{-1}$)
100	0.45
200	0.72
300	1.45
400	2 95
500	5 30
600	8.70
700	13 50
800	20.40
900	28.10
1000	38 00

(L.D.W.)

* An X-unit is 10^{-11} cm. (See **X-Rays; Gas Absorption.**)

ABSORPTION SPECTRUM. The **spectrum** of radiation which has been filtered through a material medium. When white light traverses a transparent medium, a certain portion of it is absorbed, the amount varying, in general, progressively with the frequency, of which the **absorption coefficient** is a function. Analysis of the transmitted light may, however, reveal that certain frequency ranges are absorbed to a degree out of all proportion to the adjacent regions; that is, with a distinct selectivity. These abnormally absorbed frequencies constitute, collectively, the "absorption spectrum" of the medium, and appear as dark lines or bands in the otherwise continuous spectrum of the transmitted light. The phenomenon is not confined to the visible range, but may be found to extend throughout the spectrum from the far infra-red to the extreme ultra-violet and into the x-ray region.

A study of such spectra shows that the lines or bands therein accurately coincide in frequency with certain lines or bands of the emission spectra of the same substances. This was formerly attributed to **resonance** of electronic vibrations, but is now more satisfactorily explained by **quantum theory** on the assumption that those quanta of the incident radiation which are absorbed are able to excite atoms or molecules of the medium to some (but not all) of the energy levels involved in the production of the complete emission spectrum.

A very familiar example is the spectrum of sunlight, which is crossed by innumerable dark lines—the **Fraunhofer lines**—from which so much has been learned about the constitution of the **sun.**

A noteworthy characteristic of selective absorption is found in the existence of certain anomalies in the refractive index in the neighborhood of absorption frequencies; discussed under **Dispersion.** (L.D.W.)

ABSORPTION TOWER. Gas Absorption.

ABSORPTIVITY. Thermal Radiation.

ABUTMENT. A **bridge** abutment is a **masonry** or **concrete** structure which functions both as a **pier** and as a **retaining wall.** It must support the end of the bridge and hold the abutting earth in position. The simple abutment consists of a **footing,** a breast or cross wall, a bridge seat, a back wall, and usually companion wing walls The footing transfers the loads to the supporting soil, consequently the area in contact with the soil must be large enough to insure a safe bearing pressure. The breast wall must be large enough to withstand safely the combined effects of the bridge loads, its own weight and the pressure of the soil back of the abutment. The bridge seat is the surface which supports the end **bearings** of the bridge. The back wall supports the earth above the bridge seat. The wing walls are usually attached to both ends of the breast wall and are used to retain the side slopes of the fill at the end of the abutment. (C.W.C.)

ABVOLT. Electric and Magnetic Units.

ABYSSAL FAUNA. The animals found in the depths of the ocean below 600 fathoms. The abysses are characterized by darkness, low temperature, great pressure, and the absence of plant life due to the lack of light. Grotesque form and the extensive development of light-producing organs are frequent among abyssal animals. (A.W.L.)

ABYSSAL ROCKS. Proposed by Brögger as a general term for deep-seated **igneous** rocks, or those which have crystallized from **magmas** far below the surface of the earth, very slowly and under great pressure. **Granite** is a typical abyssal rock. The term **Plutonic** is synonymous. (R.M.F.)

ACACIA. Leguminosae: tribe Mimosae. A very large genus of trees and shrubs, particularly abundant in Africa and Australia. The small flowers are aggregated into ball-like or elongate clusters, which are quite conspicuous. The leaves are rather diverse in shape; quite commonly they are dissected into compound pinnate forms; in other instances, especially in Australian species, they are reduced even to a point where only the flattened petiole (see **Leaf**), called a phyllode, remains. This petiole grows with the edges vertical, a fact which some have

been led to construe as a protective adaptation against too intense sunlight on the surface. Several species, particularly those growing in Africa and tropical Asia, yield products of commercial value. For example, from *Acacia Senegal* gum arabic is obtained; and from *A. Catechu*, a brown or black dye called cutch. Many species are valuable timber trees. Certain tropical American species are of particular interest because of the curious pairs of thorns, which are united at their base. These thorns are often hollowed out and used as nests by species of stinging ants. (R.M.W.)

ACANTHITE. **Argentite.**

ACANTHOCEPHALA. Worms with recurved spines at the anterior end, parasitic in the intestines of vertebrates. They are usually regarded as a class of roundworms (**Nemathelminthes**). (A.W.L.)

ACANTHUS. Acanthaceae. Acanthus is a small genus of Mediterranean plants largely grown for ornamental purposes. The flowers are white or various shades of red. The leaves of these plants are the source of the more or less conventionalized architectural design called the acanthus. (R.M.W.)

ACARINA. The order of **Arachnida** which includes the **mites** and **ticks.** (A.W.L.)

ACCELERATED FLIGHT. When the velocity of an airplane along its flight path contains elements of acceleration, the structure receives increments of inertia loading which may prove to be far more severe upon the structure than the loading imposed by the static weight of the airplane and its contents. Consequently, accelerated flight has been the subject of extensive analytical and experimental investigation. Acceleration of rectilinear velocity, as by increasing engine power in straight level flight, is of small import, since radial accelerations resulting from curvilinear flight at constant speed are so large as to be the critical influence. Cases of curved flight paths capable of accelerations of several g (acceleration of gravity, i.e., 32.2 ft. per sec.^{2}) are quick pull-ups (or "zooms") from high-speed rectilinear flight, spins, steeply banked turns, loops. The magnitude of the effect of accelerated flight is well illustrated by the case of a flight path curved in a vertical plane. With a constant tangential speed of 120 m p h., our airplane will experience a radial acceleration of $4g$, even though the radius of curvature be as great at 250′. (See **Load Factor.**) (F.T.M.)

ACCELERATION. The rate of change of the **velocity** with respect to the time is called acceleration. It is expressed mathematically by $\frac{dv}{dt}$, the vector derivative of the velocity, v with respect to the time, t. If the motion is in a straight line whose position is clearly understood, it is convenient to treat the velocity v and the acceleration $\frac{dv}{dt}$ as scalars with appropriate algebraic signs; otherwise they must be treated by vector methods.

Acceleration may be rectilinear or curvilinear, depending upon whether the path of motion is a straight line or a curved line. A body which moves along a curved path has acceleration components at every point. One component is in the direction of the tangent to the curve and is equal to the rate of change of the speed at the point. For uniform circular motion this component is zero. The second component is normal to the tangent and is equal to the square of the tangential **speed** divided by the **radius of curvature** at the point. This normal component which is directed toward the center of curvature also equals the square of the **angular velocity** multiplied by the radius of curvature. The acceleration due to gravity is equal to an increase in the velocity of about 32.2 ft. per sec. per sec. at the earth's surface and is of prime importance since it is the ratio of the weight to the **mass** of a body. For examples of acceleration in both curved and linear motion, see **Kinematics.** (L.D.W.)

ACCELERATORS, RUBBER. **Rubber and Accelerators.**

ACCELEROMETER. The accelerometer is an instrument for determining the acceleration of the system with which it moves. Work in accelerometry is becoming increasingly important as means of transport continue to provide higher motive speeds for the use of mankind. The principal instrument in this field of work is the accelerometer. It has been used in airplane work to study the stresses that the airplane structure undergoes, and to determine how long these stresses last. The records can also be used to study pilots' ability, especially in landings and acrobatic maneuvers. Other uses for this instrument are the study of the oscillations of automobile springs, the pickup and braking power of automobiles, the side load on tires or rails when rounding curves, and study of vibrations of various sorts. The accelerometer should have a natural period of vibration which is considerably higher than that of any shocks it may experience. In addition, it should give a graphic, easily interpreted record, and it should be rugged, strong, and accurate. Not all these characteristics can be met by one design, and accelerometers suitable for measuring the accelerations produced in certain flight maneuvers are unsatisfactory for measuring landing shock accelerations. One style of the accelerometer is the seismograph type. Unfortunately, this instrument records displacements against an axis of time sequence, and accelerations are not read directly. The slope of the displaced curve is the rate of change of displacement with time; in other words, the velocity. If the velocity is determined and plotted, a similar measurement of slope gives the rate of change of velocity with time, and this is the acceleration. Thus the record of a seismograph type of accelerometer must be differentiated twice in order to obtain accelerations, for.

$$v = \frac{ds}{dt}$$

$$a = \frac{dv}{dt}$$

$$\text{Hence: } a = \frac{d^2s}{dt^2}$$

While this type of instrument has its certain uses, it has been superseded for most accelerometry work by more practical designs. (F.T.M.)

ACCESSORY NIDAMENTAL GLAND. A gland of the female reproductive system in the **squids** and allied species. (A.W.L.)

ACCOMMODATION. The power of altering the focus of the eye so that divergent light rays may be brought to a point on the retina. (See **Vision.**) (R.S.M.)

ACCOUCHEMENT. Confinement, or delivery of a baby, by an **obstetrician** or midwife. (R.S.M.)

ACCOUCHEUR. An **obstetrician** or midwife. (R.S.M.)

ACCRETION. Used in mineralogy and geology to define the process by which inorganic bodies grow larger by the addition of material onto the external surface. (R.M.F.)

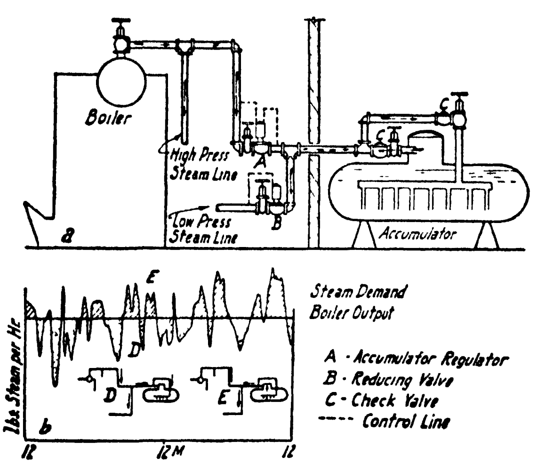
ACCUMULATOR, HYDRAULIC. The hydraulic accumulator is a hydraulic machine consisting of verti-

cal cylinders with weighted pistons or plungers under which a certain amount of water can be stored, and is, consequently, available for doing work at the pressure yielded by the weighted piston. The accumulator feature is obtained by virtue of the fact that while the water may be discharged rapidly, giving large hydraulic power for short periods of time, it may be refilled by a comparatively small and low-powered pump working a much longer time.

Another type of hydraulic accumulator is the pumped storage plant, now being looked on with considerable favor by electric power systems for the economic carrying of variable load. As employed in conjunction with steam generating stations, steam turbine-driven centrifugal pumps raise water from a lower to an upper pool with off-peak power. During the peak-load periods this water is released to the lower pool through a hydraulic turbo-generator as rapidly as is needed to give the required power. The hydraulic storage of power of this nature is essentially a high head development, low head equipment and hydraulic losses being too expensive. In favorable locations the over-all efficiency of conversion and storage may not need to be greater than 50% in order to justify the project. (F.T.M.)

ACCUMULATOR, STEAM. The steam accumulator is an effective means for smoothing out irregular steam demand into a uniform boiler output. Its operation is based upon the fact that the heat contained in water in a liquid form varies with the pressure of the water. Thus in a tank of water under pressure with the water at the saturation temperature, a decrease of pressure on the tank will be accompanied by a release of some of the heat energy held by the water, and a consequent flashing of a portion of the water into steam This process can be continued with the production of steam at ever decreasing pressures until the lower pressure limit is reached. Since the heat required to evaporate a pound of water is much more than the heat of the liquid at the commonly used pressures, only 20–40% of the weight of water in a charged accumulator tank can be converted into steam

An accumulator installation is shown by diagram in the accompanying figure The irregular steam demand



The Ruths steam accumulator.

is assumed to be that of an industrial process using considerable quantities of low-pressure steam, while the desired boiler output is shown as the straight line. The accumulator must absorb steam during the valleys which occur below the steady boiler output line and supply steam during the peaks. The direction of steam flow when charging the accumulator is shown at *D*, while at *E* is the flow diagram for accumulator discharging. (F.T.M.)

AC-DC RECEIVERS. These are radio receivers designed without **transformers** in the **power supply** so they may be connected to either **alternating-current** or **direct-current circuits.** The heaters or filaments of the

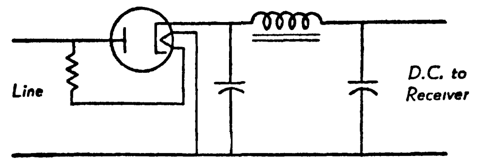


Plate supply of ac-dc receiver.

various **tubes** are connected in series with the proper series or parallel resistors to adjust the current to the correct value. The d-c voltage for the plates is obtained from a rectifier-filter circuit connected directly to the line. A simple half-wave type is shown Such supplies prevent the use of a direct ground since the 110-volt line has one side grounded and there is always the possibility of connecting the receiver plug so it would short the line if the receiver were grounded. (L.R.Q.)

ACERDISE. See boehmite under **Lepidocrocite.**

ACETALDEHYDE. Acetaldehyde ($CH_3 \cdot CHO$) is a colorless, odorous liquid, boiling point 20° C., miscible with water, alcohol, or ether in all proportions Acetaldehyde reacts with many chemicals in a marked manner, (1) with ammonio-silver nitrate ("Tollen's solution"), to form metallic **silver,** either as a black precipitate or as an adherent mirror film on glass, (2) with alkaline **cupric** solution ("Fehling's solution") to form **cuprous** oxide, red to yellow precipitate, (3) with rosaniline (fuchsine, magenta), which has been decolorized by sulfurous acid ("Schiff's solution"), the pink color of rosaniline is restored, (4) with **sodium** hydroxide, upon warming, a yellow to brown resin of unpleasant odor separates (this reaction is given by aldehydes immediately following acetaldehyde in the series, but not by **formaldehyde, furfuraldehyde** or **benzaldehyde**), (5) with anhydrous **ammonia,** to form aldehyde-ammonia ($CH_3 \cdot CHOH \cdot NH_2$), white solid, melting point 97° C., boiling point 111° C., with decomposition, (6) with concentrated **sulfuric acid,** heat is evolved, and with rise of temperature, paraldehyde ($(C_2H_4O)_3$ or $CH_3 \cdot CH{<}\begin{matrix} OCH(CH_3) \\ OCH(CH_3) \end{matrix}{>}O$), colorless liquid, boiling point 124° C., slightly soluble in water, is formed, (7) with acids, below 0° C., forms metaldehyde $(C_2H_4O)_x$ white solid, sublimes at about 115° C. without melting but with partial conversion to acetaldehyde, (8) with dilute **hydrochloric acid** or dilute **sodium** hydroxide, aldol ($CH_3 \cdot CHOH \cdot CH_2 \cdot CHO$) slowly forms, (9) with **phosphorus** pentachloride, forms ethylidene chloride ($CH_3 \cdot CHCl_2$), colorless liquid, boiling point 58° C., (10) with ethyl **alcohol** and dry hydrogen chloride, forms **acetal,** 1,1-diethyoxyethane ($CH_3 \cdot CH(OC_2H_5)_2$), colorless liquid, boiling point 104° C, (11) with **hydrocyanic acid,** forms acetaldehyde cyanhydrin ($CH_3 \cdot CHOH \cdot CN$), readily converted into alpha-hydroxypropionic acid ($CH_3 \cdot CHOH \cdot COOH$), (12) with sodium hydrogen **sulfite,** forms acetaldehyde sodium bisulfite ($CH_3 \cdot CHOH \cdot SO_3Na$), white solid, from which acetaldehyde is readily recoverable by treatment with sodium carbonate solution, (13) with **hydroxylamine** hydrochloride forms acetaldoxime ($CH_3CH{:}NOH$), white solid, melting point 47° C., (14) with phenyl**hydrazine,** forms acetaldehyde phenylhydrazone ($CH_3 \cdot CH{:}N \cdot NH \cdot C_6H_5$), white solid, melting point 98° C., (15) with magnesium methyl iodide in anhydrous ether (**"Grignard's solution"**), yields, after reaction with water, isopropyl alcohol ($(CH_3)_2CHOH$), a secondary alcohol, (16) with **semicarbazide,** forms acetaldehyde semicarbazone ($CH_3 \cdot CH{:}N \cdot NH \cdot CO \cdot NH_2$), white solid, melting

point 162° C., (17) with **chlorine**, forms trichloroacetaldehyde ("chloral") ($CCl_3 \cdot CHO$), (18) with **hydrogen sulfide**, forms thio-acetaldehyde ($CH_3 \cdot CHS$ or $(CH_3 \cdot CHS)_3$). Acetaldehyde stands chemically between ethyl **alcohol** on one hand—to which it can be reduced—and **acetic acid** on the other hand—to which it can be oxidized. These reactions of acetaldehyde, coupled with its ready formation from **acetylene** by mercuric sulfate solution as a catalyzer, open up a vast field of organic chemistry with acetaldehyde as raw material: acetaldehyde hydrogenated to ethyl alcohol; oxygenated to acetic acid, thence to acetone, acetic anhydride, vinyl acetate, vinyl alcohol. Acetaldehyde is also formed by the regulated oxidation of ethyl alcohol by such a reagent as sodium dichromate in sulfuric acid (chromic sulfate also produced). Reactions (1), (3), (14) and (16) above are most commonly used in the detection of acetaldehyde. (R.K.S.)

ACETALS. Organic compounds of the general formula $RCH(OR')(OR'')$. They are formed by the reaction of **aldehydes** with **alcohols** in the presence of small amounts of acids or certain inorganic salts. They are stable toward alkali, are volatile and insoluble in water but are decomposed into aldehyde by the action of acids. The last reaction is often used as a source of aldehydes. (R.K.S.)

ACETANILIDE. **Aniline.**

ACETIC ACID AND ACETATES. Acetic acid ($H \cdot C_2H_3O_2$ or $CH_3 \cdot COOH$) is a colorless liquid, melting point 16.6° C., boiling point 118° C, miscible with water, alcohol, or ether in all proportions. Acetic acid solution reacts with alkalis to form acetates, e.g., **sodium** acetate, **calcium** acetate; similarly, with some oxides, e.g, **lead** acetate; with carbonates, e.g., **sodium** acetate, **calcium** acetate, **magnesium** acetate; with some sulfides, e.g., **zinc** acetate, **manganese** acetate. **Ferric** acetate solution, upon boiling, yields red precipitate of basic ferric acetate. Acetic acid solution attacks many metals, liberating hydrogen and forming acetate, e.g., magnesium, zinc, iron. Acetic acid is an important organic substance, with alcohols forming **esters** (acetates); with **phosphorus** trichloride forming acetyl chloride ($CH_3 \cdot CO \cdot Cl$), which is an important reagent for transfer of the acetyl (CH_3CO-) group; forming **acetic anhydride,** also an acetyl reagent; forming **acetone** and calcium carbonate when passed over a suitable **catalyzer** (**barium** carbonate) or when calcium acetate is heated; forming **methane** (and sodium carbonate) when sodium acetate is heated with sodium hydroxide; forming mono-, di-, tri-**chloroacetic** (or **bromoacetic**) **acids** by reaction with chlorine (or bromine) from which **hydroxy-** and **amino-**, **aldehydic-**, **dibasic acids,** respectively, may be made; forming **acetamide** when **ammonium** acetate is distilled. Acetic acid dissolves sulfur and phosphorus, is an important solvent for organic substances, and causes painful wounds when it comes in contact with the skin. Normal acetates are soluble, basic acetates insoluble. The latter are important in their compounds with lead, copper ("verdigris"). Acetic acid is made (1) by destructive distillation of wood. Dilute acid is obtained in the aqueous distillate, recovered by neutralization with **calcium** hydroxide, and then evaporation and recovery of calcium acetate; (2) from calcium or sodium acetate, acetic acid of high strength is made by distillation with concentrated **sulfuric acid;** (3) by the action of bacteria on dilute ethyl alcohol, containing the proper food materials for the bacteria, dilute acetic acid (vinegar) is produced. The vinegar contains, besides acetic acid and water, the materials characteristic of the alcohol and the process used; (4) by the reaction of acetaldehyde and air over a suitable catalyzer. Acetic acid is used as has been suggested by its reactions, (1) in the preparation of many organic substances, notably, cellulose acetate, as a non-inflammable photographic film and also as a textile fiber; (2) in the preparation of many acetates and basic acetates and carbonates (white lead in conjunction with carbon dioxide); (3) as a weak, moderately cheap acid; (4) as a solvent when concentrated, for organic chemicals; (5) in pharmaceutical preparations, dyeing, rubber, artificial leather.

Esters (acetates of various alcohols) of note are:

Methyl acetate (CH_3COOCH_3), boiling point 57° C.

Ethyl acetate ($CH_3COOC_2H_5$), boiling point 77° C.

Propyl acetate ($CH_3COOC_3H_7$), boiling point 102° C.

Butyl acetate ($CH_3COOC_4H_9$), boiling point 125° C.

Amyl acetate ($CH_3COOC_5H_{11}$), boiling point 149° C.

Glycol monoacetate ($CH_3COOCH_2 \cdot CH_2OH$), boiling point 182° C.

Glycol diacetate ($CH_3COOCH_2 \cdot CH_2COOCH_3$), boiling point 190° C.

Glyceryl monoacetate (monoacetin) ($CH_2OH \cdot CHOH \cdot CH_2OOCCH_3$) decomposes upon heating.

Glyceryl diacetate (diacetin) ($CH_2OH \cdot CHOOCCH_3 \cdot CH_2OOCCH_3$), melting point 40° C., boiling point 176° C. at 40 mm. pressure.

Glyceryl triacetate (triacetin) ($CH_2OOCH_3 \cdot CHOOCCH_3 \cdot CH_2OOCCH_3$), melting point −78° C., boiling point 259° C.

Glucose pentacetate ($C_6H_6(OH)(COOCH_3)_5$), melting point 113° C., sublimes.

Cellulose triacetate ($C_6H_5(OH)_2(COOCH_3)_3$).

Cellulose tetracetate ($C_6H_5(OH)(COOCH_3)_4$), softens at about 150° C.

Cellulose pentacetate ($C_6H_5(COOCH_3)_5$).

Cetyl acetate ($CH_3COOC_{16}H_{33}$), melting point 22° C., boiling point 200° C. at 15 mm. pressure.

Phenyl acetate ($CH_3COOC_6H_5$), boiling point 195° C.

Acetates may be detected by formation of foul-smelling cacodyl (poisonous) on heating with dry arsenic trioxide. (R.K.S.)

ACETOACETIC ACID ESTER. This is an important organic liquid of the formula $CH_3(CO)CH_2 \cdot COOC_2H_5$, which is used as a starting point for the synthesis of **ketones** of the type $CH_3(CO)CHR'R''$ and acids of the type $R'R''CHCOOH$ where R′ and R″ are hydrocarbon **radicals.** The ethyl ester of acetoacetic acid is made by treating ethyl acetate (see **Esters**) with sodium. (R.K.S.)

ACETONE. Acetone ($CH_3 \cdot CO \cdot CH_3$) is a colorless, odorous liquid, boiling point 56° C., miscible in all proportions with water, alcohol, or ether. Acetone reacts with many chemicals in a marked manner, (1) with **phosphorus** pentachloride, yields acetone chloride ($(CH_3)_2CCl_2$), (2) with **hydrogen chloride** dry, yields both mesityl oxide ($CH_3COCH{:}C(CH_3)_2$), liquid, boiling point 132° C., and phorone ($(CH_3)_2C{:}CHCOCH{:}C(CH_3)_2$), yellow solid, melting point 28° C, (3) with concentrated **sulfuric acid,** yields mesitylene (C_6H_3-$(CH_3)_3$) (1,3,5), (4) with **ammonia,** yields acetone amines, e.g., diacetoneamine ($C_6H_{12}ONH$), (5) with **hydrogen cyanide,** yields acetone cyanhydrin ($(CH_3)_2$-$CHOH \cdot CN$), readily converted into alpha-hydroxy acid ($(CH_3)_2CHOH \cdot COOH$), (6) with sodium hydrogen **sulfite,** forms acetone sodium bisulfite ($(CH_3)_2COH \cdot SO_3Na$), white solid, from which acetone is readily recoverable by treatment with sodium carbonate solution, (7) with **hydroxylamine** hydrochloride, forms acetoxime ($(CH_3)_2C{:}NOH$), solid, melting point 60° C., (8) with **phenylhydrazine,** yields acetonephenylhydrazone ($(CH_3)_2C{:}NNHC_6H_5 \cdot H_2O$), solid, melting point 16° C., anhydrous compound, melting point 42° C., (9) with **semicarbazide,** forms acetonesemicarbazone ($(CH_3)C{:}NNHCONH_2$), solid, melting point 189° C., (10) with magnesium methyl iodide in anhydrous ether ("**Grignard's solution**"), yields, after reaction with water, trimethylcarbinol ($(CH_3)_3COH$), a tertiary alcohol, (11) with ethyl thioalcohol and hydrogen chloride

dry, yields mercaptol ($(CH_3)_2C(SC_2H_5)_2$), (12) with **hypochlorite, hypobromite,** or **hypoiodite solution,** yields chloroform ($CHCl_3$), bromoform ($CHBr_3$) or iodoform (CHI_3), respectively, (13) with most reducing agents, forms isopropyl alcohol ($(CH_3)_2CHOH$), a secondary alcohol, but with **sodium** amalgam forms pinacone ($(CH_3)_2COH \cdot COH(CH_3)_2$), (14) with **sodium** dichromate and sulfuric acid, forms **acetic acid** (CH_3-$COOH$) plus **carbon dioxide** (CO_2). When acetone vapor is passed through a tube at a dull red heat, **ketene** ($CH_2{:}CO$) and **methane** (CH_4) are formed. Acetone is made (1) by heating **calcium** acetate at 400° C., calcium carbonate being simultaneously formed, (2) by passing **acetic acid** vapor over a heated catalyzer, e.g., **barium** carbonate, **manganese** carbonate, (3) by fermentation of **starch** by specific bacteria, normal-**butyl alcohol** being simultaneously produced, (4) in the water condensate (approximately 0.5% acetone) in the destructive distillation of wood, and, (5) in the urine of persons having **diabetes.** Acetone may be detected by the addition of acetic acid and sodium nitroprusside (trace). The appearance of a violet color in the interface between this solution and a layer of ammonium hydroxide indicates acetone Acetone is used (1) as a solvent, e.g., for **acetylene,** (2) as a solvent for **cellulose** and glyceryl esters in the manufacture of celluloid, smokeless powders, airplane dopes, varnishes, (3) in the preparation of **chloroform, iodoform, sulfonal.** (R.K.S.)

ACETOPHENONE. Aldehydes, Ketones and Related Compounds.

ACETYL CHLORIDE. Chlorine.

ACETYLENE. Acetylene, ethyne (C_2H_2 or $CH{:}CH$) is a colorless gas, of characteristic odor, moderately poisonous, boiling point −84° C., density, 1.17 grams per liter at 0° C. and 760 mm (specific gravity 0.91, air equal to 1 00), slightly soluble in water or alcohol, very soluble in acetone (300 volumes of acetylene in 1 volume acetone at 12 atmospheres pressure), burns when ignited in air with a luminous sooty flame, requiring a specially devised burner for illumination purposes, forms an explosive mixture with air over a wide range (about 3% to 80% acetylene), explosive when compressed to 2 or more atmospheres, but safe when dissolved in acetone, of high fuel value (1455 B.T U. per cubic foot). Acetylene reacts (1) with **chlorine,** to form acetylene tetrachloride ($C_2H_2Cl_4$ or $CHCl_2 \cdot CHCl_2$) or acetylene dichloride ($C_2H_2Cl_2$ or $CHCl{:}CHCl$), (2) with **bromine,** to form acetylene tetrabromide ($C_2H_2Br_4$ or $CHBr_2 \cdot CHBr_2$) or acetylene dibromide ($C_2H_2Br_2$ or $CHBr{:}CHBr$), (3) with **hydrogen chloride** (bromide, iodide), to form ethylene monochloride ($CH_2{:}CHCl$) (monobromide, monoiodide), and 1,1-dichloroethane, ethylidene chloride ($CH_3 \cdot CHCl_2$) (dibromide, diiodide), (4) with water in the presence of a **catalyzer,** e.g., mercuric sulfate, to form **acetaldehyde** ($CH_3 \cdot CHO$), (5) with **hydrogen,** in the presence of a catalyzer, e g., finely divided nickel heated, to form **ethylene** (C_2H_4) or **ethane** (C_2H_6), (6) with metals, such as copper or nickel, when moist, also lead or zinc, when moist and unpurified. Tin is not attacked. Sodium yields, upon heating, the compounds C_2HNa and C_2Na_2. (7) With ammonio-**cuprous** (or silver) salt solution, to form cuprous (or silver) acetylide (C_2Cu_2), dark red precipitate, explosive when dry, and yielding acetylene upon treatment with acid, (8) with **mercuric** chloride solution, to form trichloromercuric acetaldehyde ($C(HgCl)_3 \cdot CHO$), precipitate, which yields with hydrochloric acid acetaldehyde plus mercuric chloride. Acetylene is made by reaction of **calcium** carbide and water, calcium hydroxide being simultaneously formed, and is formed when the gas in a Bunsen burner burns at the base of the burner; and when hydrogen is passed through a carbon **arc** (about 7% acetylene in the exit gas). Acetylene may be detected by the formation of explosive copper acetylide Acetylene is used (1) as a fuel with oxygen for high temperature flames, (2) as an illuminant, (3) in the manufacture of **acetaldehyde,** from which a variety of chemicals is prepared, (4) in the manufacture of chloro-derivatives, thus:

Acetylene → vinyl chloride by HCl, Cu_2Cl_2, NH_4Cl
vinyl acetylene by same, which yields chloroprene
→ tetrachloroethane by Cl_2, which yields trichloroethylene ($CHCl{:}CCl_2$), pentachloroethane ($CHCl_2 \cdot CCl_3$), perchloroethylene ($CCl_2{:}CCl_2$), hexachloroethane ($CCl_3 \cdot CCl_3$). (R.K.S.)

ACETYLSALICYLIC ACID. A **drug** commonly known as "aspirin" (See **Salicylic Acid.**) It is used for relief of milder forms of pain, especially joint and muscle pain. It also tends to reduce fever. It does not harm the heart, contrary to popular opinion. This drug is used in massive doses in acute rheumatic fever. (R S M.)

ACHENE. An achene is a single-seeded **fruit,** which does not split when mature, and which has the seed free from the ovary wall except at the point of attachment. (R.M.W.)

ACHEULEAN. Paleontology of Man.

ACHILLES, TENDON OF. In man the prominent tendon at the back of the ankle, extending from the muscle of the calf to the heel. Technically it is the tendon which attaches the gastrocnemius and soleus muscles to the calcaneum or heel bone. The name derived from human anatomy is used in relation to other vertebrates. (A.W L)

Tendon of Achilles.

ACHLORHYDRIA. Absence of **hydrochloric acid** in the **stomach.** This may occur normally in older people, and in certain diseases, such as **cancer** of the stomach, and pernicious **anemia.** (D M.H.)

ACHOLIA. Absence or lack of secretion of **bile.** (R.S.M.)

ACHONDRITES. A form of stony meteorites without **chondri,** and having textures similar to those of some terrestrial rocks (R.M.F.)

ACHRAS SAPOTA. Sapodilla. Sapotaceae. A large tree native to the forests of Central and tropical South America, the fruit of which is an edible berry. Its greatest value is in its **latex** product, which yields chicle. The chicle-gathering industry is centered in Yucatan and Central America. The tapping is done in the rainy season. The tapper climbs to a height of 30–50′, and with a machete cuts a series of connecting zig-zag diagonal gashes in the bark as he descends. At the bottom of this series of cuts he attaches a cup, into which the latex flows. The crude substance is collected, boiled down to eliminate much of its water and the coagulated product pressed into 20–25 lb. blocks. This substance, chicle, varies in quality from the best grade, which is milk-white in color, to pinkish or darker grades, which have received less care in preparation. Each tree yields about 2½ lbs. of chicle during one season and may be tapped every 6 years. The blocks of chicle are shipped largely to the United States, where they are melted and cleaned, flavored and sweetened, and then marketed as the familiar chewing gum. This use of the latex of the

Sapodilla is not new, since the Aztecs and their predecessors knew of it and used it When first introduced into the United States it was tried as a rubber substitute, but proved unsuitable. (R.M.W.)

ACHROIT. Tourmaline.

ACHROMATISM. Chromatic Aberration.

ACICULITE. Aikinite.

ACICULUM. A strong internal **seta** found in the **parapodia** of annelid worms. (A W.L)

ACID ANHYDRIDES. Acids, Carboxylic.

ACID ROCK. According to A. Holmes an igneous rock which contains 66% **silica** is said to be acidic. The term is gradually going out of use. Since the geologist uses acid in a different sense from the chemist, Clarke has proposed persilicic for igneous rocks which are relatively rich in silica. (R.M.F.)

ACIDOSIS. A condition occurring in the body in which **acids** are absorbed or form in excess of their elimination or **neutralization.** The alkali reserve of the body is disturbed, the first step being a decrease in amount of bicarbonate (see **Carbon**) in the **blood.** The opposite condition results from excess formation or ingestion of **alkalis,** or from prolonged loss of acid from the stomach. The resulting condition is known as alkalosis. In this condition the alkali reserve is increased over the normal limit.

Ordinarily, excess acid or alkali formed or taken into the body does not cause either of these conditions. This is due to the ability of the body to protect itself automatically by preserving the acid-base **equilibrium.** This is accomplished by several mechanisms. In general, the balance is maintained by elimination, oxidation, excretion and neutralization. The buffer substances in the blood—the **salts, haemoglobin** and **protein**—act to lessen the change toward increased acid or alkali concentration. Further, there is a reserve of alkali to take care of any excess acid. This reserve of alkali consists of sodium bicarbonate, di-potassium phosphate and protein salts. Acidosis only occurs when the buffer substances and alkali reserve are depleted.

Excess acid or alkali can be eliminated by the kidneys and by the respiratory mechanism through its power to throw off greater or lesser concentrations of **carbon dioxide.** Neutralization of acid occurs with **ammonia** formed by the body **metabolism.** These are all normal bodily processes and the mechanism of equilibrium can still be maintained in abnormal conditions without producing an acidosis or alkalosis unless certain adverse factors enter into the picture.

Acidosis may occur in many conditions, usually those of serious nature. They are (1) starvation or inadequate intake of water or food (especially **carbohydrates**), or during acute **infections,** (2) after prolonged **anaesthesia,** (3) in diseases accompanied by severe **diarrhea** and vomiting, (4) in severe untreated **diabetes,** (5) in advanced kidney and heart disease.

Alkalosis may result from (1) prolonged vomiting with excess loss of **hydrochloric acid** from the stomach, (2) prolonged increase in the respiratory rate as is seen in certain disorders and in higher altitudes, (3) excess ingestion of alkalis by mouth as might occur in the treatment of peptic ulcer and in other conditions. This may also occur through prolonged use of alkali products by the laity due to the pernicious advertising of these products on the radio and in advertisements for treatment of imaginary and non-existent "acid conditions" and indigestion. (D.M.H.)

ACIDS, BASES AND SALTS. These are chemical compounds classified as **electrolytes.** Acids are electrolytes which furnish **hydrogen ions,** e.g., $HCl \rightarrow H^+ + Cl^-$. Bases are electrolytes which furnish **hydroxyl ions,** e.g., $NaOH \rightarrow Na^+ + OH^-$. Salts are electrolytes which furnish neither hydrogen nor hydroxyl ions, e.g., $NaCl \rightarrow Na^+ + Cl^-$. Salts are formed by the combination of equivalent weights of an acid and a base, a process called neutralization. The result is the formation of a salt and the combination of the hydrogen and hydroxyl ions to form water. $HCl + NaOH \rightarrow NaCl + H_2O$.

Water as an electrolyte occupies a unique position in that it furnishes both hydrogen ions and hydroxyl ions in equal amounts. In pure water the concentration of each of these ions is 10^{-7} moles per liter. The product of the hydrogen times the hydroxyl concentration is always constant and equal to 10^{-14}. When the hydrogen ion concentration is greater than 10^{-7} due to the presence of an acid, the hydroxyl ion concentration becomes less than 10^{-7} and the solution is said to be acidic. When the hydroxyl ion concentration is greater than 10^{-7} due to the presence of a base the hydrogen ion concentration adjusts itself to a value less than 10^{-7}. Thus the hydrogen ion concentration is a measure of the acidity or basicity of a solution. It is usually defined by stating the pH which is the negative logarithm of the hydrogen ion concentration (in moles per liter). The process of neutralization, whereby an acid and a base in **solution** react to form a salt—actually hydrogen ion of the acid and hydroxyl ion of the base react to form water leaving the **cation** of the base and the **anion** of the salt by recombination—is discussed elsewhere. (See **Reactions Involving Recombination of Ions.**)

Upon evaporation of the solvent, the salt is obtained as such, frequently as crystals, sometimes with, sometimes without water of crystallization. (See **Reactions Involving Water.**)

A salt can be defined as "a system built from oppositely charged ions which do not neutralize each other" (Kilpatrick, 1935). In this sense **hydrochloric acid** (H^+Cl^-) and **sodium** hydroxide (Na^+OH^-) are salts. Acids are those salts whose cation is hydrogen ion, H^+ (probably acid (H_3O^+) dissociating to proton (H^+) plus base (H_2O)), and bases those whose anion is hydroxyl, OH^- (probably acid (water) dissociating to proton (H^+) plus base (OH^-)). A salt (1) when dissolved in an ionizing solvent, e g., sodium chloride in water, is a good conductor of electricity, and (2) when in the solid state forms a **crystal** lattice, e.g., sodium chloride crystals possess a definite lattice structure for both sodium cations (Na^+) and chloride anions (Cl^-), determinable by examination with x-rays.

A broader definition than that confined to solutions is demanded in some fields of chemistry, for example, in high temperature reactions of acids, bases, salts. In the formation of metallurgical **slags,** at furnace temperatures, **calcium** oxide is used as base and **silicon** oxide and **aluminum** oxide, as acids, and calcium aluminosilicate is produced as a fused salt. Sodium carbonate and silicon oxide when fused react to form the salt sodium silicate with the evolution of carbon dioxide. In this sense:

$$\left[\begin{array}{l}\text{Oxide of any}\\ \text{element func-}\\ \text{tioning as a}\\ \text{metal, that is,}\\ \text{as a base.}\end{array}\right] \text{ plus } \left[\begin{array}{l}\text{Oxide of any}\\ \text{element func-}\\ \text{tioning as a}\\ \text{non-metal, that}\\ \text{is, as an acid.}\end{array}\right] \text{ yields [Salt]}$$

Iron and **sulfur** when heated react to form the salt ferrous sulfide. In this sense:

[Metal] plus [Non-metal] yields [Salt]

Salts are, therefore, prepared (1) from solutions of acids and bases by neutralization, and separation by

evaporation and crystallization, (2) from solutions of two salts by precipitation where the solubility of the salt formed is slight, e.g., **silver** nitrate solution plus sodium **chloride** solution yields silver chloride precipitate (almost all as solid) and sodium nitrate as sodium cations and nitrate anions in solution (recoverable as sodium nitrate solid by separation of silver chloride and subsequent evaporation of the solution), (3) from fusion of a basic oxide (or its suitable compound—sodium carbonate above) and an acidic oxide or its suitable compound—ammonium **phosphate** since ammonium and hydroxyl are volatilized as ammonia and water, thus: ammonium sodium hydrogen phosphate $\begin{matrix} NH_4 \searrow \\ Na \rightarrow P^{5+}O_4 \\ H \nearrow \end{matrix}$ yields sodium **metaphosphate** $Na—P^{5+}O_3$ upon heating), (4) from reaction of a metal and a non-metal.

Reactions of acids as such in solution without decomposition of anion, are dependent upon the presence of hydrogen cation (H^+) and the anion of the acid

Reactions of bases as such in solution without decomposition of cation, are dependent upon the presence of the cation of the base and hydroxyl anion (OH^-).

Reactions of salts as such in solution, without decomposition of cation or anion, are dependent upon the presence of the cation and the anion of the salt.

Acids in general (exceptions are common) attack metals, **oxides, carbonates, sulfides, sulfites,** with the formation of a salt and, in the respective instances, hydrogen, water, **carbon dioxide, hydrogen sulfide, sulfur dioxide.** For Ionization Constants of Acids, see **Carboxylic Acids, Amines and Amides** for Nitrogen acids), of Bases, see **Amines and Amides** (for Nitrogen bases) (R K S)

ACIDS, CARBOXYLIC, AND RELATED COMPOUNDS (Acid Anhydrides, Lactones, Lactides).

Carboxylic **acids** (containing carboxyl group—COOH) are of wide variety as to constitution, physical properties, methods of preparation, and uses, well illustrated by reference to some of the particular acids, such as formic, acetic, stearic, oleic, benzoic Several hydroxy acids (containing hydroxyl group, $-OH$, and carboxyl group, $-COOH$) are found in important natural materials Such acids are tartaric, citric, malic, lactic. The ionization constants of some organic acids and of **phenol,** which constants indicate the relative strength of these acids, are as follows, arranged in decreasing acidic strength:

Acid	Ionation Constant of Acid
Trichloroacetic	2×10^{-1}
Dichloroacetic	5×10^{-2}
Oxalic	4×10^{-2}
Malonic	2×10^{-3}
Chloroacetic	2×10^{-3}
Phthalic	1×10^{-3}
Tartaric	1×10^{-3}
Salicylic	1×10^{-3}
Citric	8×10^{-4}
Malic	4×10^{-4}
Formic	2×10^{-4}
Lactic	1×10^{-4}
Benzoic	7×10^{-5}
Succinic	7×10^{-5}
Acetic	2×10^{-5}
Carbonic	3×10^{-7}
Hydrocyanic	7×10^{-10}
Phenol	1×10^{-10}

Acids that are insoluble or slightly soluble in water may usually be titrated after dissolving in alcohol, and the amount of sodium hydroxide standard solution required to neutralize a given weight of the acid is characteristic, and an indication of the particular acid involved.

Substituted chloro-, bromo-, iodo-, amino- and cyano-, thio-, phospho-, acids will be found under the elements **chlorine, bromine, iodine, nitrogen, sulfur, phosphorus,** respectively.

Primary **alcohols** or **aldehydes,** upon **oxidation,** yield the corresponding carboxylic acids, and methyl **ketones** yield acetic acid, among other products. Regulated reduction of carboxylic acids yields the corresponding aldehydes or primary alcohols.

When the sodium or calcium salt of carboxylic acids is heated with **sodium** hydroxide or **calcium** oxide the **hydrocarbon** containing one less carbon atom than the acid is formed, e.g., sodium acetate yields **methane,** sodium benzoate yields **benzene** (and Na_2CO_3 or $CaCO_3$).

Acid **anhydrides** and acid or acyl **chlorides** are important organic reagents, e g, acetic anhydride ($(CH_3CO)_2O$), benzoyl chloride (C_6H_5COCl).

When hydroxy- or amino-acids lose water or ammonia, respectively, characteristic reactions occur, as follows:

Hydroxy- or Amino Acid	Acid	Product
Alpha-hydroxy	$CH_3CHOHCOOH$	Lactide: $H_3C\ CH—CO—O$ $O—CO—HC\ CH_3$
Beta-hydroxy	$CH_3CHOHCH_2COOH$	Unsaturated acid. $CH_3CH{:}CH\ COOH$
Gamma hydroxy	$CH_3CHOHCH_2CH_2COOH$	Gamma-lactone $CH_3CHCH_2CH_2CO$ —O—
Alpha-amino	$CH_2NH_2\ COOH$	Lactim $CH_2—NH—CO$ $CO—NH—CH_2$
Beta-amino	$CH_2NH_2 \cdot CH_2 \cdot COOH$	Unsaturated acid $CH_2{:}CH\ COOH$
Gamma-amino	$CH_2NH_2\ CH_2\ CH_2\ COOH$	Gamma-lactam. $CHCH_2CH_2CO$ —NH—

(R.K.S.)

ACIDS, INORGANIC. See individual acids.

ACINIFORM GLANDS. The glands of **spiders** which produce the silk used to enclose the prey. (A.W.L.)

ACME. **Screw Thread.**

ACMITE-AEGIRITE. Acmite is a comparatively rare rockmaking mineral, usually found in nephelite **syenites** or other **nephelite** or **leucite** bearing rocks, as phonolites. Chemically it is a **soda-iron** silicate, and its name refers to its sharply pointed **monoclinic** crystals. Bluntly terminated crystals form the variety aegirite, named for Aegir, the Icelandic sea god.

Acmite has a hardness of 6 to 6.5, specific gravity 3.5, vitreous luster, color brown to green, transparent to opaque.

The original acmite locality is in Norway. Greenland furnishes fine specimens. United States localities are Magnet Cove, Arkansas, and Libby, Montana, where a variety carrying **vanadium** occurs. (E.S.C.S.)

ACNE. *Acne vulgaris* is a chronic infection of the **sebaceous glands** in the skin. The exact cause of this disease is not known. It is usually first seen in certain susceptible individuals with the onset of **puberty.** Because of its occurrence at this time, many observers believe that the primary cause is bound up with physiological and biochemical changes associated with sudden increase in function of the sex glands. It usually disappears on reaching adult life, although in certain individuals the disease becomes chronic. It is most often seen in people with oily skins. The external opening on the skin of the sebaceous gland becomes narrowed, the sebaceous material cannot escape and the retained material serves as a source of irritation, secondarily infecting the surrounding tissue. Acne may cause permanent scarring. It is most successfully treated by **x-rays** and **ultra-violet rays** or sunlight, although vaccines, local treatment of the skin, glandular and hygienic methods are also useful in certain cases. It is not contagious.

Acne rosacea is a much less-common skin disorder characterized by a red bulbous nose, and inflammation and infection of the flush area of the face. Its etiology is unknown. (D.M.H.)

ACOELA. An order of free-living flatworms in which the alimentary tract is without a cavity. (A.W.L.)

ACOELOMATA. Animals without a **coelom.** The term is applied especially to the flatworms, nemertine worms, and roundworms; these animals have attained the mesoderm in which the body cavity develops but it remains a more or less continuous mass with small spaces if any. (A.W.L.)

ACONINE. **Alkaloids.**

ACONITINE. **Alkaloids.**

ACONTIA. Filaments bearing stinging cells in **sea anemones.** They can be shot out through the mouth or through special pores when the animal is stimulated. (A.W.L.)

ACORN TUBE. A small vacuum **tube** in a glass envelope shaped somewhat like an acorn and designed to have a minimum of **interelectrode capacitance** and lead inductance. Such characteristics are essential for successful operation at very high frequencies. (See **Ultra High Frequencies.**) (L.R.Q.)

ACOUSTICS. In the broader sense, acoustics is the physics of **sound,** treated in all its aspects. Commonly, however, the term is restricted to a study of the transmission of sound through various media or in various enclosures or coduits, including the effects of reflection, refraction, interference, diffraction, and absorption.

Of especial importance is the acoustics of buildings and auditoriums. Sound from a source within an enclosure tends to build up to a maximum of intensity, limited only by leakage (as through open doors or windows) and by the dissipation of the energy through air viscosity and absorption. It is thus much easier to make one's self heard in a small, closed room than out of doors. In a large enclosure, an important factor is "reverberation," that is, the re-echoing of sounds among the various exposed solid surfaces, which, if too protracted, may impair the distinctness of audition. Sabine defines the "reverberation time" as the period in which the intensity falls to one millionth of its steady value after the source is suddenly silenced. He obtained an empirical formula for the time in seconds, as follows: $T = 0.164V/a$. Here V is the volume of the room in cu. meters, while a is the sum of the equivalent absorptions of the various exposed surfaces, each equal to the product of the area of the surface in sq. meters by its "acoustic absorptivity" (ratio of absorbed to incident sound energy). Sabine found the absorptivity of plaster to be 0.033, glass 0.027, wooden floor 0.061, linoleum 0.120, etc., and the absorption of an audience to be 0.44 sq. meter per person (equivalent to 0.44 sq. meter of a perfect absorber), of each empty wooden seat 0.008 sq. meter, of each upholstered seat 0.30 sq. meter, etc. It is thus possible to predict by Sabine's law the reverberation time of an auditorium before it is built, and to judge whether it will be good for piano music (for which the best value is about 1.1 sec.) or for speaking (for which a smaller value is desirable). Another factor in auditorium acoustics is concerned with "focusing" the sounds from the stage upon the audience by means of properly shaped walls and ceiling, a problem which Sabine studied by means of photographs of sound waves in small model enclosures.

The investigation of such problems as the passage of sound through simple tubes, or tubes having branches, or through cavities of various shapes, such as musical instruments or resonators, reveal certain remarkable analogies to the theory of a-c circuits. Thus we encounter the property known as acoustic impedance; with its components, acoustic resistance and acoustic reactance, the latter being dependent upon the acoustic inertance (an-

alogous to inductance) and acoustic compliance (sometimes called acoustic capacitance). These correspond to analogous properties of a-c circuits, in which the electric impulses may be compared to acoustic waves with electricity as the medium. The acoustic resistance, inertance, and compliance depend, respectively, upon the viscosity, the density, and the elasticity of the medium. It is an interesting fact that by causing sound to pass through a suitably designed conduit, such as the two-branched or shunted "Quincke tube," certain frequencies may be suppressed, much as electric oscillations are suppressed by electric wave filters. This effect is due to the interference of wave trains following different routes. (L.D.W.)

ACRASPEDOTE. A medusa without a **velum,** such as the common **jellyfishes.** (A.W.L.)

ACRIDINE. **Pyridine and Related Compounds.**

ACRIFLAVINE. An acridine (see **Pyridine and Related Compounds**) **dye,** reddish-yellow in color, which is used in dilute solution in the treatment of infected or contaminated wounds. It possesses germicidal and antiseptic properties and, when used in the proper dilution, will not injure body tissues. In weak solutions it is also used for irrigation of diseased body cavities, as, for instance, the urinary **bladder** when **cystitis** is present. (R.S.M.)

ACROCYST. A chamber formed of the **blastostyle** of some species of **hydroids,** in which the eggs develop. (A.W.L.)

ACRODONT. **Dentition.**

ACROLEIN. **Aldehydes, Ketones, and Related Compounds.**

ACROMEGALIA or **ACROMEGALY.** A disease of the **pituitary gland** characterized by overgrowth of the skull, thickening and coarsening of the skin and facial features, enlargement and protrusion of the lower jaw, and enlargement of the flat bones, particularly the hands and feet. There is also a general enlargement of the heart and abdominal organs.

The etiology is an increase and overfunctioning of the cells staining with acid dyes, the acidophilic group of cells in the anterior pituitary gland, usually with the formation of an acidophilic **adenoma.** If the overfunction occurs before the growth of the long bones is complete, gigantism occurs; if it occurs in adult life, acromegaly is the result. (D.M.H.)

ACRYLIC ACID. **Alcohols and Ethers.**

ACTINIUM. Symbol: Ac. A radioactive element, and also a series of radioactive elements. (See **Radioactive Changes.**)

ACTINOLITE. The term for a **calcium-iron-magnesium amphibole,** the formula being $Ca_2(Fe,Mg)_5(OH)_2(Si_4O_{11})_2$, but the amount of iron varies considerably. It occurs as bladed crystals or in fibrous or granular masses. Its hardness is 5–6, specific gravity 2.9–3.2, color green to greyish green, transparent to opaque, luster vitreous to silky or waxy. Iron in the **ferrous** state is believed to be the cause of its green color. Actinolite derives its name from the frequent radiated groups of crystals. Actinolite is found in **schists,** often with **serpentine** and in **igneous** rocks probably as the result of the alteration of **pyroxene.** The schists of the Swiss Alps carry actinolite. It is also found in Austria, Saxony, Norway, Japan, and Canada in the provinces of Quebec and Ontario. In the United States actinolite occurs in Massachusetts, Pennsylvania, Maryland, and as a **zinc-manganese** bearing variety in New Jersey. (E.S.C.S.)

ACTINOMYCOSIS. A disease of man and certain domestic animals ("lumpy jaw" of cattle) caused by a pathogenic **fungus** commonly known as the ray fungus. The organism is not infrequently carried in the normal mouth without harm. Infection usually occurs by invasion from the mouth. Rarely, the source of infection may be outside the body. Actinomycosis is not contagious.

Clinically, several forms occur, depending on the site of localization. The cervico-facial involving primarily the face and neck, the abdominal, and pulmonary are the common types. Any viscus may be involved, however. The lesions are always multiple with chronic **abscesses** which burrow, spread, leave sinus tracts, and heal with the production of large amounts of fibrous tissue. The organism is found in the **pus** in actinomycotic abscesses as pin-point-sized yellow granules.

The mortality is high in the abdominal and pulmonary types; the commoner cervico-facial type has a better prognosis.

Treatment is surgical plus long continued use of **sulfonamide drugs.** In the past, iodides have been used, and recently **penicillin,** the latter with some success. (D.M.H.)

ACTINOMYXIDA. **Sporozoa.**

ACTINON. Symbol: An. A radioactive element of the actinium series. (See **Radioactive Changes.**)

ACTINOZOA. **Anthozoa.**

ACTINULA. A larval form of **hydroid,** resembling a **polyp** with a short stalk. (A.W.L.)

ACTION. In certain discussions of dynamics there is need of an expression for the product of twice the mean total **kinetic energy** of a system of particles, during a specified interval of time, by the duration of the interval. This product is called the "action." Mathematically, it is expressed by

$$S = 2\int_{t_0}^{t} E_K dt,$$

in which E_K is the kinetic energy and t_0 and t are the times of beginning and ending of the interval. The c.g.s. unit of action is the erg-second. The well known "Planck's constant h" is the common designation for the elementary quantum of action.

Maupertuis enunciated a law, known as the "principle of least action," which states that when a dynamic system is left to itself, unaffected by outside forces, so that its total energy cannot alter, any spontaneous change within the system takes place in such fashion that the action has the least possible value during the interval covered by the change. (L.D.W.)

ACTIVATION. **Cathode.**

ADAMANT. The term adamant was used by Theophrastus about 300 B.C. to mean **lodestone.** Chaucer as well as other medieval writers used it similarly. There seems to have been some confusion as to the exact nature of adamant, some regarded it as referring either to lodestone or **diamond** or to a mythical substance combining the properties of both. Curiously enough there is a rare variety of bort (black diamond) which is magnetic, due to the mechanical admixture of particles of **magnetite.** Whether this sort of black diamond was known to the ancients is wholly a matter of conjecture. The long continued association of the idea of hardness with the word adamant has led to our modern usage of the term as well as the derived, adamantine, **referring** to the luster of substances of high refractive indices. (E.S.C.S.)

ADAMANTINE SPAR. **Corundum.**

ADANSONIA DIGITATA. Baobab. Bombaceae. A tree of tropical Africa, the baobab has an extremely large trunk (the diameter sometimes exceeding 30′), but

does not attain great height. The natives often excavate the light, easily worked wood and use the hollow so formed for shelter. The large fruit has a mucilaginous pulp which is often eaten; and the bark yields a fiber used for making cloth and rope. (R.M.W.)

ADAPTABILITY. A property of living matter through which it makes adjustments to its environment. It is accomplished chiefly through four fundamental properties: irritability, conductivity, contractility, and secretion. The first enables it to receive impressions from surrounding factors. Through the second all parts of the living body are in communication with the parts capable of receiving stimuli from without. The last two are the more common means of response. Contractility is the source of movement by which spatial adjustments of the body in relation to its surroundings are accomplished, and secretion is a means of producing special substances, such as digestive fluids, involved in the animal's reactions.

Adaptability is expressed in all of the actions of an organism, and in a more permanent way in the **adaptation** of the individual and species to its mode of life. (A.W.L.)

ADAPTATION. The process of modification of the living organism to adjust it to the conditions of its environment. Also an inherited character that enables the organism to meet certain environmental conditions.

All living things are adapted for a mode of life characteristic of their kind, under equally characteristic environmental conditions. They receive from previous generations a heritage (see **Heredity**) that fits them for this mode of life, and all characters in the hereditary complex that are of definite use are adaptive. Wings, for example, are an essential flight adaptation, and fins or some similar appendage are commonly found as adaptations for swimming. Other characters such as the colors and patterns of butterfly wings are usually of no apparent value and may be called non-adaptive or incidental.

Regardless of its adaptive heritage, however, each individual encounters some fluctuations in its environment to which it must adjust itself. The resulting changes in its body are adaptive, no less than its inherited structures. They are the acquired characters of biological literature, and have also been called individual adaptations. Human beings commonly experience two fine examples of this kind of adaptation in the calluses formed by the skin in response to friction, and the deposition of pigment, or tanning, as a protection against excessive ultra-violet light. A less evident result of exposure to ultra-violet light is a protective thickening of the epidermis, probably as important as the accompanying increase in pigmentation.

The relation of adaptations of both kinds to individual life is evident in any living thing. Beyond this field they are of great importance in theories of **evolution**, the one as the extensive result of evolutionary processes of the past and the other as a possible factor in the accomplishment of changes of evolutionary significance. (A.W.L.)

ADAPTIVE (RADIAL) EVOLUTION. Fossil Invertebrates and Fossil Reptiles.

ADAPTIVE RADIATION. A principle of evolutionary development formulated by Henry Fairfield Osborn. It assumes that a limited stock of animals in a restricted area tends to become broken up in the course of time into species adapted to various special habitats. Thus, as originally applied to the **mammals**, the ancestral stock is supposed to have been a small walking species with generalized teeth and omnivorous habits. From it the running and jumping species, burrowers and fliers, and species adapted to eat flesh or to eat vegetation are supposed to have evolved.

Although originally applied to the mammals the principle has been found to apply equally well to other groups, such as the insects. In some cases divergent or branching evolution has been noted, as well as radiating development from a common central stock. (A.W.L.)

ADDAX. Mammalia, Artiodactyla. An **antelope,** *Addax nasomaculatus,* of northern Africa and Arabia. (A.W.L.)

ADDENDUM. In a gear tooth, the distance from the pitch circle to the outer circle or top of the tooth. (H.C.H.)

ADDER. Reptilia, Serpentes. A term loosely applied to various **snakes,** both poisonous and non-poisonous. Among the poisonous species are the resplendent adders of Asia, which are near the American coral snakes, and the deadly crait and raj-samp of India, also known as the blue adder and banded adder, respectively. Australia also has two poisonous species, the death adders (*Acanthophis*), and the deadly puff-adder, *Bitis arietans,* is found throughout Africa. In North America the last name is applied to the harmless hog-nosed snakes, although spreading adder is perhaps more commonly used. (A.W.L.)

ADDICT. One who makes a habit of taking a narcotic **drug,** and comes to require it to maintain a sense of well-being. The narcotics chiefly used by addicts are **morphine, heroin,** and **cocaine.** (D.M.H.)

ADDISON'S DISEASE. A chronic disease due to destruction of the **cortex** of the **adrenal glands,** and diminution of the cortical **hormone.** It is characterized by marked weakness, wasting, brown pigmentation of the skin and **mucous membranes,** disturbances of the digestive tract and low **blood pressure.** The blood **electrolyte** balance is upset, with low chlorides, low sodium and high potassium. The disease is gradual, with progressive exhaustion and debility, eventually resulting in death if treatment is not given.

At autopsy, **tuberculosis** of the adrenal glands is the most common finding, although primary **atrophy,** or other destructive lesions may be found

Treatment is with cortical hormone and salt—which produce a prompt remission in the acute disease; both of these must be continued throughout life much as insulin must be supplied to a diabetic With adequate therapy, the patient with Addison's disease may lead a relatively normal life for years. (D.M.H.)

ADDITION. Addition is one of the fundamental operations with **numbers,** by which two or more numbers are combined to give a number; the result is called the sum.

Addition of numbers is subject to several fundamental rules or so-called laws: the commutative and associative laws, and in combination with **multiplication,** the distributive law.

The commutative law for addition of numbers is expressed by the formula

$$a + b = b + a$$

for any two numbers a and b; in words, the sum of any two numbers is the same in whatever order they are added. A similar statement applies to the sum of more than two numbers.

The associative law for addition of numbers is expressed by

$$(a + b) + c = a + (b + c)$$

for any three numbers a, b, c; in words, the sum of any three numbers is the same in whatever manner they are grouped. This is easily extended to more than three numbers.

The absolute value of a positive number is the number itself, and the absolute value of a negative number is its numerical value regardless of algebraic sign.

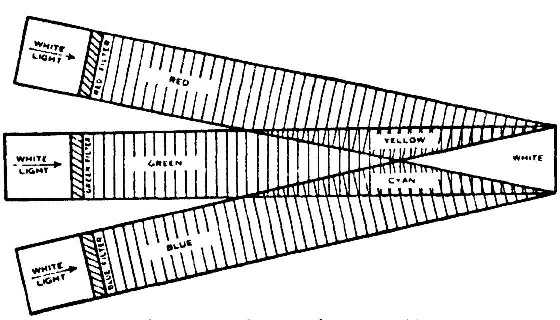
To add two numbers having like signs, add their absolute values and prefix the common sign.

To add two numbers having unlike signs, take the difference of their absolute values and prefix to it the sign of the number having the larger absolute value. (L.L.S.)

ADDITIVE COLOR PROCESS. A system of color photography in which the color synthesis is obtained by the addition of colors one to another in the form of light rather than as colorants. This color addition may take place (1) by the simultaneous projection of two or more (usually three) **color images** onto a screen, (2) by the projection of the color images in rapid succession onto a screen or (3) by viewing minutely divided juxtaposed color images. The principles of color analysis for a subject to be reproduced by an additive color process are discussed more fully under **color photography.** In the case of a 3-color process, three color records are made from the subject recording, in terms of silver densities, the relative amounts of red, green and blue present in various areas of the subject.

When the additive synthesis is to be made by simultaneous projection, positives are made from the color separation negatives and projected with a triple lantern onto a screen through red, green and blue filters. The registered color images give all colors of the subject due to simple color addition, red plus green making yellow, red plus blue appearing magenta, etc.

When the additive synthesis is made by successive viewing, the same three color images must be flashed onto the screen in such rapid succession that the individual red, green and blue images are not apparent. Simple color addition is again obtained but this time use is made of the persistence of vision to "mix" tne colors.



(*Neblette, Photography, 4th ed.*)

The third type of additive synthesis makes use of the fact that small dots of different colors, when viewed from such a distance that they are no longer individually visible, form a single color by simple color addition. The three color images in this type of process are generally side-by-side in the space normally occupied by a single image. The red record image will be composed of a number of red dots or markings of differing density which in their sum total will compose the red record image. Alongside the red markings will be green and blue markings, without any overlapping. When viewed at such a distance that the colored markings are at, or below, the limit of visual resolution, the color sensation from any given area will be the integrated color of the markings comprising the area—an additive color mixture.

All three types of additive color synthesis have been used commercially but, even with their high color fidelity, the expensive and inconvenient viewing or projecting devices have seriously limited the use of the first two types of addition. The third method, a color mosaic formed photographically, has been the most successful of the additive color processes and has found widespread use in the mosaic **screen processes** and in the **lenticular process.** (H.C.C.)

ADENINE. Akaloids.

ADENITIS. Inflammation or infection of glandular tissue. The term generally is applied to inflammation of the **lymph** glands. Cervical adenitis is inflammation of the glands of the neck, axillary adenitis is inflammation of the glands of the **axilla;** inguinal adenitis is inflammation of the glands of the groin; mesenteric adenitis is inflammation of the glands in the mesentery of the small intestine. The infection can be local, originating in the glands or by drainage into the glands from a nearby inflammation, or it can accompany a systemic disease. (R.S M.)

ADENOIDS. An increase in the normal **lymphoid tissue** in the nasopharynx (see **Pharynx**), which is sometimes referred to as the third or pharyngeal tonsil The condition usually accompanies enlargement of the tonsils and, as with their enlargement, chronic infection plays an important part in its development. The disease, usually occurring during childhood, is easily recognized when fully developed by the dull facial expression, inability to blow the nose, mouth-breathing, snoring, and nasal twang to the voice. It is usually accompanied by frequent head colds and ear infections. The treatment is surgical removal; this is usually carried out at the same time as tonsillectomy. (D.M.H.)

ADENOMA. A benign **tumor** consisting of an encapsulated overgrowth of epithelial cells of a glandular structure. Adenomata may occur in the **endocrine glands,** the gastro-intestinal tract, the **respiratory system,** the breast, and wherever glandular **epithelium** occurs. (See **Gland.**) (D.M.H)

ADHESION. This term is used both in medicine and in physics.

In medicine, adhesion refers specifically to an abnormal adherence of tissues of the body, either directly, surface to surface, or by bands of connective **tissue.** This most commonly occurs as a result of inflammation, as in **joints,** where adhesions between the lining membranes (synovial membranes) can produce stiffness and pain. In the peritoneal cavity following various degrees of peritoneal infection, bands or adhesions can occur between the peritoneal coats of solid organs or intestines These occasionally cause intestinal obstruction requiring operative treatment. In the chest, as a result of various types of **pleurisy,** adhesions often form between the **pleura** covering the lung and the lining of the interior of the chest cavity.

In physics, the terms adhesion and cohesion designate intermolecular forces holding matter together. The tendency of matter to hold itself together or to cling to other matter is one of its most characteristic properties. Adhesion and cohesion are merely different aspects of the same phenomenon, which is apparently of the nature of an intermolecular attraction. We speak of cohesion as an interaction between adjacent parts of the same body and as acting throughout the interior of its substance, while adhesion refers to a similar interaction between the closely contiguous surfaces of adjacent bodies.

There is reason to believe that as two neutral molecules or atoms approach each other, their mutual potential energy reaches a minimum value at a certain equilibrium distance; so that work would be necessary either to push them closer or to pull them farther apart, because of forces which are probably electrical. (See **Least Energy Principle.**) The distribution of molecules, ions, or atoms in a solid is determined by this type of equi-

librium, and the regular spacing of crystal structure and the architecture of the molecule itself are dependent upon it. Any force tending to diminish the equilibrium distance meets with the rapidly increasing reaction of compressive elasticity, while any force tending to increase it is opposed by cohesion, which increases at first and then rapidly diminishes toward zero as the point of fracture is reached.

The behavior of bodies which are aggregates of crystals or of fibers is complicated by the friction and the adhesion of the adjacent particles, so that the ultimate strength of a material is not a safe measure of its true cohesion. A filament of spun quartz may be much stronger when freshly drawn than later when crystallization replaces its initial cohesion by the adhesion between separate crystals; and yarn is not nearly so strong as the cotton or wool fiber composing it.

Adhesion increases with closeness of contact. This explains why one must bear down with a pencil to make a mark on paper, why fine dust adheres more firmly than coarse sand, and why a liquid or a gum usually sticks to a solid better than another solid does.

Cohesion in liquids is usually less, and in gases it is always much less, than in solids. Aside from the pressure in liquids due to external causes, there is presumably a very great internal or intrinsic pressure, due to intermolecular attraction, but not capable of direct measurement by means at our disposal. The clearest evidences of its existence are the work required for thermal **expansion** and the phenomenon of **surface tension.** (R.S.M., L.D.W., D.M.H.)

ADHESIVES. Materials such as glue which cause two surfaces to become united are known as adhesives. There is a wide variety of these materials, and a large number make use of water as the medium in which they are used. These include glue, starch, dextrin, gum arabic, casein, sodium silicate, and rubber latex. Usually glue is used hot and is odorous, whereas casein can be used cold and is odorless. A typical preparation is made of 100 parts by weight of casein, 10 of alum, 5 of sodium carbonate in 500 of water. Many organic proteins, of which glue is one, are useful as adhesives, including the residues from the extraction of oils from seeds, such as soy bean.

Media other than water are used in the case of such adhesives as rubber. These are made with varying degrees of fluidity and of rubber content, depending upon their use, as for adhesive tape. The principal solvents are chlorinated hydrocarbons, carbon disulfide, coal tar hydrocarbons, petroleum hydrocarbons, and ethyl ether. In this order there is progressively decreasing solubility for rubber, and increasing viscosity with the same rubber content.

Adhesives are sometimes classified, according to the purpose for which they are used, into those (1) for bonding rigid surfaces, such as wood, metal, glass, and porcelain, where the bond does not have to be flexible. Water as a medium is generally satisfactory in such cases; and (2) for bonding flexible surfaces, such as paper, cloth, and leather, where it is important that the bond possess as high a degree of flexibility as the less flexible of the bonded surfaces. In the book-binding and shoe-manufacturing trades there is need to make temporary bondings in the processing, and rosin may be used to increase the tackiness even though rosin has a deleterious effect on rubber over a period of time.

Several of the solvents mentioned for rubber are also effective media for adhesives made of nitrocellulose, cellulose acetate, or numerous synthetic plastics, in which field great advances have been made. In cementing synthetic plastic transparent sheets the use of an organic solvent softens the surfaces sufficiently so that, when pressure is applied and the solvent is evaporated, the two surfaces adhere.

Resistance to temperature changes and to humidity conditions are frequently determining factors in the selection of the proper adhesive for given materials. (R.K.S.)

ADIABATIC PROCESSES. Changes in matter which take place without transfer of heat. When heat is imparted to or withdrawn from a body of matter, the body generally experiences changes of temperature, pressure, and volume, and sometimes a change of state. These changes severally involve the absorption or the release of energy, which may be regarded respectively as positive and negative energy increments, and the algebraic sum of which is equivalent to the quantity of heat supplied or withdrawn. If the body in question could be provided with perfect thermal insulation, so that no heat could enter or leave it, then any change requiring energy, which might take place within the body, would necessarily be effected at the expense of energy yielded by other internal changes. But a rise of temperature might be caused by heat generated in compression. Processes of this sort, unaccompanied by any transfer of heat across the insulating boundaries of the body, are said to be adiabatic.

For an ideal gas, the pressure and the volume maintain, during an adiabatic expansion or compression, a relationship in which the pressure changes proportionately more with volume than for an isothermal change. This adiabatic relation, for a very slow change, is represented by the formula pv^γ = constant, in which γ is the ratio of the **specific heat** of the gas at constant pressure to that at constant volume (for air, about 1.41). Corresponding formulas are readily obtained for pressure and temperature and for volume and temperature by utilizing the **ideal gas law.** It may be shown that such **reversible** adiabatic **processes** are also isentropic, that is, they take place without change of **entropy.** Adiabatic processes, though hardly realizable in practice, are often considered in thermodynamic reasoning. (L.D.W.)

ADIABATIC PROCESSES IN THE ATMOSPHERE. When a parcel of air is moved from one position to another with respect to surrounding air, in such a manner that energy does not flow across the boundaries of the parcel, thermal changes taking place within the parcel are said to be adiabatic changes. Any process in the atmosphere occurring adiabatically is known as an adiabatic process.

Adiabatic processes during which the air involved remains unsaturated throughout the process are relatively simple. Adiabatic processes involving condensation or evaporation are considerably complicated by heat of condensation. The first law of thermodynamics applied to a parcel of unsaturated air of unit mass stipulates:

$$dq = c_v dT + A p dv$$

which, when combined with the gas equation, becomes

$$dq = (c_v + AR)dT - \frac{ART}{p} dp.$$

For the adiabatic process, this becomes

$$\frac{dT}{T} = \frac{AR}{c_p}\frac{dp}{p}$$

which, upon integration, becomes

$$\frac{T}{T_0} = \left(\frac{p}{p_0}\right)^{\frac{AR}{c_p}} = \left(\frac{p}{p_0}\right)^{.288}.$$

Temperature and dew-point changes within a moving parcel are of primary meteorological importance. Dry adiabatic horizontal transfer of a parcel from higher to lower or lower to higher pressure is of only minor consequence because of the comparatively small magnitude of pressure change. Dry adiabatic vertical transfer of a parcel, however, is one of the important meteorological processes. Temperature decrease in a rising

and increase in a sinking parcel amounts to very nearly 9.8° C. per kilometer, or 5.4° F. per 1000′. Dew-point changes in a vertically moving unsaturated parcel are considerably less. Dew point decreases in rising air at a rate between 0.7° F. per 1000′ and 1.0° F. per 1000′, depending on the air temperature, and increases in sinking air at the same rate.

Adiabatic changes in a saturated parcel (as long as the parcel remains saturated) are known as moist adiabatic or pseudo-adiabatic changes in contrast to dry adiabatic changes in an unsaturated parcel of air. Pseudo-adiabatic changes are by no means constant or simple. In a parcel rising pseudo-adiabatically the temperature decrease is always less than the dry adiabatic temperature change by an amount depending on the weight of the water being condensed and the temperature at which condensation occurs. Condensation releases the latent heat of vaporization within the parcel which partially counteracts dry adiabatic cooling. The rate of cooling in rising saturated air varies from about 1.8° F. per 1000′ in warm air at relatively high altitudes to 5 3° F. per 1000′ in very cold air at sea level. This range of cooling rates in saturated air is the direct result of the variance in the amount of water resident in a given mass of air at full saturation. Very cold air can retain only a slight amount of water whereas very warm air can hold relatively large quantities. Values of resident water vapor at saturation range from 0.01% by weight in arctic air to 3% by weight in tropical air.

Sinking saturated air remains saturated only for a comparatively short distance during which it is heated pseudo-adiabatically at a rate determined by the amount of evaporation occurring within the parcel. As soon as it becomes unsaturated, the sinking parcel descends dry-adiabatically. **Foehn winds** are examples of both pseudo-adiabatic and dry-adiabatic changes Air flowing uphill is cooled dry-adiabatically until saturated, after which it is cooled pseudo-adiabatically until it reaches the hilltop. On the lee side, the air descends dry-adiabatically. Observable results of the true foehn wind are abundant clouds and rain or snow on the windward side and clear, warm air on the lee side of a mountain range.

Dew points in saturated air rising pseudo-adiabatically decrease at the same rate as the temperature. Dew points in saturated sinking air increase at the same rate as the temperature until the air parcel is no longer saturated; then they rise slowly as previously described in connection with sinking saturated air.

A large percentage of all clouds and nearly all precipitation result from adiabatic ascent of air

Assuming increasing positive values with altitude the following relations hold.

1. Dry adiabatic temperature change with altitude:

$$\frac{\partial t}{\partial h} = -\frac{gK}{R} = -9.8^\circ \text{ C./km.}$$

where t = Temperature of parcel.
g = Gravitational constant

$$K = \frac{c_p - c_v}{c_p} = .288.$$

R = Gas constant.

2. Dry adiabatic dew-point change with altitude

$$\frac{\partial t_d}{\partial h} = -1.71 \left[1 + \frac{2t_d}{237.3} - \frac{t}{273}\right] {}^\circ\text{C./km.}$$

where t_d = Dew-point temperature in °C.
t = Air temperature in °C.

3. Pseudo-adiabatic temperature change with altitude

$$\frac{\partial t}{\partial h} = -g\left(\frac{A + .621\frac{e}{p}\frac{L}{Rt}}{c_p + .621\frac{L}{P}\frac{de}{dt}}\right) {}^\circ\text{C./km.}$$

where t = Temperature of the parcel in centigrade.
g = The gravitational constant.
A = Heat equivalent of work.
e = Water vapor pressure.
p = Air pressure
L = Heat of condensation
c_p = Specific heat at constant pressure for air.

(P.E.K.)

ADIPOCERE. Waxy matter formed by the chemical transformation of bodies protected from air by burial in moist places or by submergence in water. Grave wax. (A.W.L.)

ADIPOSE FIN. A fleshy **fin** without supporting spines, occurring behind the dorsal fin in some fishes. (A W.L)

ADIPOSIS. An excessive accumulation of fatty tissue in the body. This condition is usually caused by over-indulgence in food; in some cases heredity and disinclination to exercise play a part. In a few instances, disturbances in the endocrine glands, particularly the **pituitary** and **thyroid** are responsible for **obesity.** (D.M.H)

ADJUSTED MOMENTS. **Sheppard's Correction.**

ADJUTANT. Aves, Ciconiiformes. *Leptoptilus.* A name applied to stork-like birds (**Aves**) of several species. They occur in Africa and the Oriental region where they are valuable as scavengers From at least one species the soft downy feathers known as marabou are secured. (A.W.L.)

ADLERSTEIN. **Geothite.**

ADMIRALTY METAL. **Brass and Bronze.**

ADMITTANCE. Admittance is the reciprocal of **impedance,** hence is that quantity in an **alternating-current circuit** by which the voltage may be multiplied to give the current. It may be computed from the circuit constants by the following equation.

$$Y = \sqrt{G^2 + B^2}$$

where G is the conductance (a positive number) and B the susceptance (positive number for capacitance and negative for inductance) of the circuit. These are computed from:

$$G = \frac{R}{R^2 + X^2} = \frac{R}{Z^2}$$

$$B = \frac{X}{R^2 + X^2} = \frac{X}{Z^2}$$

R being the **resistance** and X the **reactance** of the circuit

In many types of calculations, particularly in communication circuits, it is frequently more convenient to use admittance rather than **impedance.** In parallel circuits the admittances of the various branches are added as shown to give the total admittance:

$$Y_0 = \sqrt{(G_1 + G_2 + \cdots)^2 + (B_1 + B_2 + \cdots)^2}$$

$$I_1 = VY_1,\ I_2 = VY_2, \text{ etc., } I_0 = VY_0$$

where V is the impressed voltage and I the current in the circuit. (L.R.Q.)

ADOBE. An extremely fine-grained wind-blown **clay** particularly characteristic of the arid and semi-arid south-western United States, Mexico and South America. Used by the south-western Indians and Mexicans for huts and buildings from pre-historic times. (R.M.F.)

ADOLESCENCE. The period between **puberty** and maturity; usually between the ages of 12 and 20 years. (D.M.H.)

ADRENAL GLAND (SUPRARENAL GLAND). One of the **glands** of internal secretion. The two adrenal glands are small, triangular structures situated on the upper portion of each kidney just below the diaphragm. They are composed of two portions: the internal portion, called the medulla; and the outer portion, called the cortex. Each portion has a separate secretion and function Epinephrine is secreted into the blood stream by the medullary portion. This medullary portion of the gland is derived from the same embryonic cells that form the sympathetic **nervous system.** Epinephrine stimulates this nervous system and the reverse is also true, that is, stimulation of this nervous system also causes additional epinephrine to be poured forth into the system. Fear, anger, excitement, sudden physical exertion, etc., are stimulating factors, both to the sympathetic nervous system, and, in turn, to the secretion of epinephrine.

The cortex of the gland secretes a hormone concerned with the regulation of carbohydrate metabolism, and the metabolism of sodium and potassium. The adrenal cortex is necessary to life. **Addison's disease** occurs when its hormone production is insufficient. (D.M.H.)

ADRENALINE (EPINEPHRINE) ($C_6H_3(OH)_2$-$CHOHCH_2NHCH_3$). One of the secretions of the **adrenal glands.** Adrenalin is the trade name for epinephrine. It is usually used either by local application or by hypodermic injection in 1:1000 solution. It is inactive when taken orally.

Normally, a sufficient amount of this substance is secreted by the gland to maintain normal tone of the blood vessels. During exercise and especially with fear, anger, danger or sudden muscular activity, the glands are stimulated and larger amounts are discharged into the blood stream. This stimulates the sympathetic nervous system with the following results: blood pressure is increased quickly and markedly, respirations are quickened and deeper, and smooth muscle is contracted. These actions are favorable for muscular exertion but unfavorable for digestion, as may easily be understood. The same reaction is seen when adrenalin is given by hypodermic injection.

Adrenalin is used medically to increase the blood pressure and restore tone to the blood vessels. It is the most rapidly acting circulatory stimulant of marked power, but owing to its transient action, it is used only in emergencies. It is used in cases of failure of the normal heart as may occur following electric shocks, etc., where it is given in dilute solution into the heart blood. Adrenalin is sometimes used to shrink mucous membranes of the nose when congestion is present. It is sometimes used to control bleeding from an oozing surface, through its action of constricting blood vessels.

A common use, which is specific, is to prevent or treat foreign **protein** reactions, as are seen when serum is given to a sensitive person, and in **hives,** hay fever and **asthma.** In the latter diseases its action is often dramatic, for the drug is a powerful dilator of constricted bronchi and the attack is usually aborted temporarily at least. (See **Hormones.**) (D.M.H.)

ADSORPTION. Adsorption is a type of adhesion which takes place at the surface of a solid or a liquid in contact with another medium, resulting in an accumulation or increased concentration of molecules from that medium in the immediate vicinity of the surface. For example, if freshly heated charcoal is placed in an enclosure with ordinary air, a condensation of certain gases occurs upon it, resulting in a reduction of pressure; or if it is placed in a solution of unrefined sugar, some of the impurities are likewise adsorbed, and thus removed from the solution. Charcoal, when activated (i.e., freed from adsorbed matter by heating) is especially effective in adsorption, probably because of the great surface area presented by its porous structure. Its use in gas masks is dependent upon this fact. **Penicillin** is recovered in one stage of the process by adsorption on activated carbon.

When **colloidal** hydroxides, notably **aluminum** hydroxide, are precipitated in a solution of acidic **dyes,** that is, those containing the groups —OH or —COOH, the dye adheres to the precipitate, yielding what is termed a lake. The "adsorption" of dirt on one's hands results from the unequal distribution of the dirt between the skin of the hands and the air or solid with which the skin comes in contact. Water is frequently ineffective in removing the dirt. The efficacy of soap in accomplishing its removal is due to the unequal distribution of dirt between skin and soap "solution," this time favoring the soap and leaving the hands clean.

At a given fixed temperature, there is a definite relation between the number of molecules adsorbed upon a surface and the pressure (if a gas) or the concentration (if a solution), which may be represented by an equation, or graphically by a curve called the adsorption isotherm. The degree of adsorption depends upon (1) the composition of the adsorbing material, (2) the condition of the surface of the adsorbing material, (3) the material to be adsorbed, (4) the temperature, and (5) the pressure (if a gas). A notable case in point is carbon. Of the finely divided varieties of carbon there are important sugar charcoal, bone black or animal black, blood charcoal, wood charcoal, coconut-shell charcoal, activated carbon. The temperature of preparation of adsorbent charcoal is an important factor, high temperatures being deleterious, and the removal (or non-removal) of gases by passing steam over the heated carbon, which operation increases the adsorptive power. Bone black is used for removing the coloring matter from raw sugar solutions. Fusel oil is removed from whiskey and poison gases from air by adsorption with the proper form of carbon. By cooling carbon in a vacuum to the temperature of liquid air, the concentration of residual gas is greatly decreased. Dewar (1906) found that 5 grams of charcoal (presumably coconut-shell charcoal) at the temperature of liquid air reduced the pressure of air in a 1-liter container from 1.7 mm. to 0.00005 mm. This is now a standard method for the production of a high vacuum, as in the **neon** lighting tube. Travers (1906), using **carbon dioxide** gas and animal charcoal, found that the concentration of gas divided by the third power of the concentration of adsorbed gas is a constant. In other cases the power to which the concentration of adsorbed gas must be raised is approximately 3 to 2.

Besides carbon, other important adsorbents in use are infusorial or diatomaceous earth, fuller's earth, clay, activated silica, and activated alumina. All surfaces that behave indifferently towards non-electrolytes have the ability to adsorb **electrolytes.**

Adsorption plays an important role in the process of **dyeing,** and in contact catalytic processes such as the conversion of **sulfur dioxide** to trioxide, and of **nitrogen** plus **hydrogen** to **ammonia.** In the case of insoluble organic acids (containing —COOH group) and substances containing hydroxyl (—OH) groups on the surface of water, the film is oriented so that the —COOH or —OH groups are attracted into the surface of the water, while their hydrocarbon ends project away from the surface of the water showing no tendency to dissolve (Langmuir).

The heat of adsorption, or wetting in this case, of starch by water is 29 **calories** per gram of dry starch. The heat of adsorption of various vapors and adsorbents has been measured. Since increase of temperature reduces adsorption, the adsorption process is accompanied by the evolution of heat. It appears that the heat liberated for a given volume of liquid filling the capillary spaces of a given adsorbent is practically constant. The heat of adsorption of hydrogen is, on **nickel, palladium, platinum, copper,** 11,700, 18,000, 13,800, 9500 calories

respectively per gram mol (2 grams) of hydrogen; and of **carbon monoxide** on platinum 35,000 calories per gram mol (28 grams) of carbon monoxide; and of **ethylene** on copper 9500 calories per gram mol (28 grams) of ethylene.

Occlusion is a type of adsorption, or perhaps more properly absorption, exhibited by metals or other solids toward gases, in which the gas is apparently incorporated in the crystal structure of the solid. Palladium thus occludes extraordinary quantities of hydrogen, with the simultaneous liberation of much heat. (L.D.W., R.K.S.)

ADULARIA. Feldspar.

ADULT. A full-grown animal. In species with a pronounced **metamorphosis** the last stage is known as the adult or in insects as the imago. Sexual maturity is characteristic of most adults but some are without sexual functions and in some species reproduction may take place in an earlier developmental stage. (A.W.L.)

ADVECTION. The transfer of air and air characteristics by horizontal motion. Fog drifts from one place to another by advection. Cold air moves from polar regions southward. Large-scale north-south advection is more prominent in the northern hemisphere than the southern, but west to east advection is prominent on both sides of the equator. (P.E.K.)

ADVECTION FOG. Fog formed because of horizontal flow of air of high dew point over much colder surfaces. (See **Fogs.**) (P.E.K.)

ADVENTITIOUS BUDS. Buds which appear elsewhere than in the leaf axils or above them. They may appear anywhere in the internode, or on roots or even on leaves, and develop either naturally or as a result of injury. The dense bunches of buds, which frequently appear on burls or in witches'-broom, may be adventitious. The buds which appear at the tops of thistle roots, particularly when the natural top of the plant is cut off, are adventitious. So also are the buds which develop on the leaves of the Begonia and **Bryophyllum.** The practice of pollarding, or cutting off the branches of a tree in such a way as to leave only the main trunk or perhaps the stumps of a few large branches, results in the development of dense groups of adventitious buds. These grow into adventitious branches which in certain willows may be long and supple and so useful in manufacturing wicker furniture. The habit of forming adventitious buds on roots is of material value, since in consequence it is possible to propagate many plants by means of root cuttings.

Pollarded trees (*Catalpa*). Numerous branches developed from adventitious buds when the stem was cut.

Adventitious **roots** also exist. They may appear from the stem where they arise in the **pericycle,** or from other tissues of the plant. The roots which appear on slips or stem cuttings are adventitious. (R.M.W.)

ADVENTITIOUS ROOTS. Adventitious Buds.

AECIOSPORES, AECIA. Rust, Fungi.

AEOLIAN DEPOSITS. Sediments and **sedimentary** rocks which are largely, if not entirely, composed of wind-blown material. Desert sands are typical aeolian sediments, characterized by relatively uniform, well-rounded particles whose surfaces are usually covered with microscopic pits due to their mutual bombardment during transportation. This pitting gives each sand grain a frosted appearance. Wind-blown sediments frequently show characteristic **cross-bedding,** ripple marks (miniature dunes) and wind-faceted pebbles (**glyptoliths**). Further evidence of their origin is the absence of fossils. Aeolian deposits are usually largely composed of **quartz** sand. An important fine-grained wind-blown deposit is **Loess.** Extensive desert deposits are also composed of **gypsum,** salt, etc. (R.M.F.)

AERATION. Aeration is an artificial method in which water and air are brought into direct contact with each other. The purpose of aeration is to release certain dissolved gases, which often cause water to have obnoxious odors or disagreeable tastes. It is also used to furnish oxygen to waters which are deficient in this element. Aeration may be accomplished in many ways. One method consists of spraying the water into the air. The same result may be obtained by allowing the water to flow in thin sheets down a slope arranged as a series of horizontal steps.

The principle of aeration is used in the treatment of sewage by a method known as the activated **sludge** process. The **sewage** is allowed to flow into an aeration tank where it is mixed with a predetermined volume of sludge. Compressed air is introduced which agitates the mixture and furnishes oxygen which is necessary for certain biological changes which take place. Sewage may also be aerated by mechanically actuated paddles which rotate the liquid and constantly bring a fresh surface in contact with the atmosphere. (C.W.C., F.T.M.)

AERENCHYMA. Spongy tissue occurring chiefly in the stems of many aquatic or marsh plants. This tissue is formed by the **phellogen** layer, and in many cases results from the separation of the cell walls, leaving extensive intercellular spaces, as in *Decodon* Such porous tissue gives great buoyancy to the stem and so helps keep the leaves up in the air and permits gas diffusion within the plant. The term aerenchyma is frequently applied to any loose porous tissue found in plants, as for example that occurring in **lenticels.** (R.M.W.)

AERIAL MAP. Photogrammetry.

AERIAL PHOTOGRAMMETRY. Photogrammetry.

AERIAL SURVEYING. Photogrammetry.

AEROBE OR AEROBIC BACTERIA. Most species of **bacteria** can grow only when there is available to them free oxygen. These are called aerobic bacteria. (Compare **Anaerobe.**) (R.M.W.)

AERODYNAMIC CENTER. This term is used with reference to airfoils and wings. It is a point, lying on the aerodynamic chord, about which the pitching **moment coefficient** has the most constant value as attitude varies. Although different airfoils exhibit some variation in aerodynamic center, most of them have a center at or near 25 per cent of the chord aft of the leading edge. (F.T.M.)

AERODYNAMIC EFFICIENCY. There is no single, rigid, and definite meaning ascribed to this term.

However, in general, it might be said that aerodynamic efficiency measures the ratio of the useful effect on a body exposed to air in motion as compared to the total effort required or to the undesirable reactions unavoidably incurred. Thus, one automotive vehicular shape would be more efficient than another when it transported, for example, five persons with equal comfort at the same speed but with less expenditure of power to overcome wind resistance than the other. Or, again, the aerodynamic efficiency of an **airfoil**, such as that employed in an airplane wing, can be measured by the ratio of the lift created to the drag entailed in creating this lift (see **Aerodynamics**). (F.T.M.)

AERODYNAMIC FORCES. Aerodynamics; Airfoil; Lift; Drag; Induced Drag; Trim.

AERODYNAMICS. Fluid mechanics is the study of reactions between fluids and solids immersed in them. Aerodynamics is a phase of the mechanics of fluids, its study being limited to the reactions caused by relative motion between the fluid and solid, with the fluid being air. Sometimes this strict definition is broadened so that *aerodynamics* may also include the reactions of gases other than air. The scope of the subject of aerodynamics is, nevertheless, broad. It encompasses the flow of gases in conduits, the effects of winds on static structures such as building, chimneys, and bridges, and the effect on moving bodies of the atmosphere through which they move. Thus the air resistance of automobiles, the flight of airplanes, and the sway of suspension bridges are examples of aerodynamic action. The field of study and application in which the subject attains its maximum importance and encounters its greatest problems is **aeronautics**. Consequently, the emphasis of the present writing is in the direction of aeronautics, particularly aviation. Normally, the object, such as wing, fuselage, wheel, etc., is in motion through still or relatively quiet air. The aerodynamic forces are the same as those prevailing had the object been at rest and the fluid moving past it at the same relative velocity. As this *inversion* is usually beneficial to comprehension of aerodynamics, it is common to employ it. This employment extends not only to visual picturization of aerodynamic forces created by air streams upon stationary airfoils and other objects, but also is customarily employed in testing these objects in moving streams. This is true of the **wind tunnel**.

As air is the common fluid of aerodynamics, a study of its properties is an excellent starting point. Most of the properties of air are described elsewhere in this volume. There is one physical concept of fundamental importance to the study of aerodynamics. It is *viscosity*. Possibly this will surprise the reader, who may have previously comprehended air as a frictionless fluid having zero viscosity—as indeed it is in many respects. Air is nearly a perfect gas. Its viscosity is only .00019 poises under standard conditions compared with .01 poise for water, and 1 poise for oil (light). There are many fields of aerodynamic study in which the air can be considered as frictionless; in fact, practically all aerodynamics except that associated with the conditions existing in a very thin layer immediately adjacent to the solid object may rest on this concept. In aerodynamic expressions the absolute viscosity, μ, is usually associated with mass density, ρ as a ratio. This is called the kinemetic viscosity, ν, which has a magnitude of .000157 ft.^{2} per sec. in standard sea level atmosphere.

At subsonic air speeds it is customary to consider the air as incompressible, and to rely on **Bernoulli's Theorem** of the interchangeability of static head and velocity head. This permits the employment of the **principle of continuity** for flow, represented by the equation

$$AV = \text{constant},$$

which means, symbolically, that the product of the cross-sectional area of flow and the velocity is a constant at all points in the path taken by a finite quantity of the fluid. If the fluid were compressible, this continuity would be

$$\rho AV = \text{constant}.$$

A streamtube in air may be visualized as an imaginary conduit through which the condition of continuity of flow of the incompressible fluid takes place. Although the flow is steady the tube is not necessarily of uniform size, but where its sectional area decreases we would anticipate an increase of velocity; furthermore, a consideration of Bernoulli's Theorem would indicate that these diminished sections of the streamtube were regions of lower static pressure than elsewhere. Although a streamtube is ordinarily imagined to have a circular cross-section, it will be convenient here to think of a streamtube as having a rectangular cross-section. If we have enough of these streamtubes, all of the same width, but whose heights may vary, as velocity varies, we might imagine them stacked, one on another, as shown in the figure, and be thus encompassing the whole flow of air through a given region. It will be convenient to think of the edges of these streamtubes as equivalent to the **streamline** pattern which is so useful in the study of the effect of air flows past solid objects. It follows that where the stream lines approach each other there is a region of lower pressure and higher velocity; conversely when they diverge. Thus converging streamtubes (and stream lines) are like nozzles, while diverging are like diffusers. The reader may then judge fluid pressure upon viewing a streamline pattern by the density of stream lines. This is readily done, qualitatively, if not quantitatively.

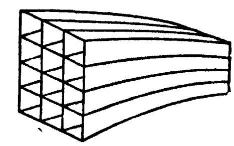


Fig. 1. Stacked streamtubes.

It is in order now to state the nature of elementary streamline patterns and explain how a complex streamline pattern may be considered to be the result of the addition of two potential forces, each capable of producing a different character of stream line in the same region. A simple potential pressure can cause a plain rectilinear streamline pattern. A cylinder rotating in still air will drag with it a circulatory pattern of flow, the stream lines of which could be represented by a series of concentric circles. The circulation stream pattern is of great importance because an airfoil is a shape which automatically induces a circulating component of air flow, which when superimposed upon a rectilinear stream provides the typical stream line pattern around an airfoil. The lifting streamline pattern of the typical airfoil could be induced in the absence of the airfoil by imposing some specific circulatory pattern of stream flow upon a rectilinear field, and this fact has been put to useful service in theoretical consideration of the aerodynamics of airfoils.

In Fig. 2*a*, a rectilinear flow is passing a static cylinder. At some distance from the cylinder the flow is unaffected by the presence of the cylinder, and the streamtubes remain of constant size throughout, but it is obvious that between this undisturbed region and the cylinder, the intermediate tubes must be smaller in order that all can be accommodated in the space immediately above and below the cylinder. The action of the individual streamtube approaching a point abreast of the center line of the cylinder is, therefore, that of a nozzle which has increased the air speed and decreased its pressure. Hence, above and below the cylinder, static pressure is less than in the free, unaffected stream. If the cylinder were in rotation, tending to set up its concen-

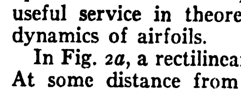

Fig. 2*a*. Cylinder at rest.

tric field of stream lines, the resulting streamline pattern would be like that shown in Fig. 2*b*, where, on one side of the cylinder, there is a reduction of static pressure due to crowding together of the streamlines, whereas on the other side there may be no change of pressure, or even an increase. Briefly, then, the presence of a circulatory component of flow in a rectilinear field is to produce a net transverse force on the object since it will be subjected to unbalanced static pressure of the fluid against its surfaces. This is the force which causes a spinning tennis ball to assume a sharply curved trajectory, and this is the force which causes the lift to exist upon an airplane wing.

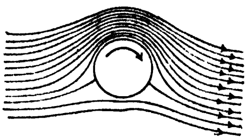

Fig. 2*b*. Rotating cylinder.

The influence of viscosity of air in aerodynamics is confined chiefly to the action of air in the **boundary layer.** Within this boundary layer (which, although extremely thin, constitutes the atmosphere immediately adjacent to the solid) the frictional qualities of air are of importance in determining the air flow. The thin boundary layer might be imagined subdivided into a great many lamina of air parallel to the surface and extending out to the limits of the boundary layer. A non-turbulent boundary layer is considered, although, as will be developed later, the boundary layer may become turbulent under certain conditions except for the lamina immediately adjacent to the stationary surface. As Fig. 3 displays, the laminar velocity, u, increases above the surface until, at the edge of the boundary layer, it equals the free stream velocity. The smaller the viscosity of the fluid, the thinner the boundary layer will be. Consequently it is extremely thin for air, but what goes on in this boundary layer is of utmost importance in aerodynamics. The first layer of air sticks or adheres to the surface, and lamina above it successively slide on each other, exerting drags that are proportional to the viscosity. The rate of change of the velocity between adjacent lamina is a measure of the unit shearing force between them, and is the unit skin friction when the lamina considered is the one in motion nearest the stationary surface. This occurs at practically zero boundary layer thickness. A curve joining the tips of velocity vectors plotted for the different lamina in the boundary layer is called a velocity profile. If u is the variable velocity, increasing from O to V across the boundary layer, then du/dy is the rate of change of velocity (also the tangent to the velocity profile) and, through the application of one of the Newtonian principles, the unit shear stress,

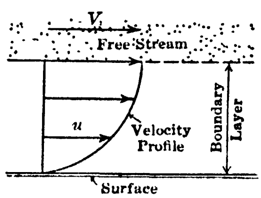

Fig. 3. Velocity profile.

$$\tau = \mu\left(\frac{du}{dy}\right)_{y=0}.$$

The proximity of streamlines to a stationary surface is now seen to produce a reaction resulting from the static pressure p existing in the flow nearest the surface, and a skin friction τ, which is, of course, tangential to the surface. The combination of these two is a force oblique to the surface. The foregoing statement premises an adherence of the streamlines to the surface, for, if they have separated from the surface, the region between will be filled with vortices of random motion, and the surface pressure cannot be definitely predicted from the character of the streamline flow. It is apparent that aerodynamic reaction is a function of μ, ρ, V, and the extent of the surface area on which the reaction takes place. Usually some one dimension l is taken to describe the size of the surface. In Engineering units the aerodynamic force F is pounds, μ is poises, ρ is slugs per square feet, and l is feet. To discover the relationship existing between the reaction and its controlling factors, it is customary to set up the dimensional relationship:

$$|F| = |\rho^a\mu^bV^cl^d|$$

and employ the methods of dimensional analysis to discover the value of a, b, c, and d. It is found that

$$|F| = \left|\left(\frac{\nu}{Vl}\right)^b\rho V^2l^2\right| \quad \text{dimensionally}$$

and

$$F = K\left(\frac{\nu}{Vl}\right)^b\rho V^2l^2 \quad \text{numerically,}$$

in which ν = Kinematic viscosity
K = A dimensionless constant
$\frac{Vl}{\nu}$ = **Reynolds number** (also dimensionless)

The product, $2K\left(\frac{\nu}{Vl}\right)^b$, is frequently given as a dimensionless coefficient C. The exponent b is of such magnitude that the Reynolds number has a minor (but not negligible) effect on C. The coefficient is affected primarily by the attitude of the body in the airstream If it is completely symmetrical, as is a sphere, this variation is non-existent, and C is a true constant except for the above-mentioned minor effect of Reynolds number variation. However, the non-symmetrical shape of an airfoil causes large and typical variations of C, depending on the attitude with which the airfoil is presented to the airstream. The force F would then be $C\frac{\rho V^2}{2}S$, or CqS, in which q is dynamic pressure, and S is some significant surface of the object. (See **Angle of Attack.**)

Flow within a streamtube may be laminar or slightly turbulent. It was stated that, in laminar flow, drag per unit area is $\mu\left(\frac{du}{dy}\right)_{y=0}$, but turbulent flow produces higher skin friction because the velocity profile is fuller close to the surface on account of turbulent energy interchange between lamina. Though at the beginning of contact between airstream and surface true laminar flow existed, it has been found that at a certain critical value of Reynolds number, determined chiefly by the linear dimension of contact passed over, the boundary layer suddenly becomes turbulent and thickens In spite of the higher skin friction, the drag on **bluff bodies** may actually become less with turbulence, because of an action, within the turbulent boundary layer, resisting separation of the stream lines from the surface. Viscous drag gradually slows down the fluid in a laminar boundary layer, and if contact with the surface is maintained over sufficient length, the innermost parts of the boundary layer will be brought to rest. This becomes the *separation point.* If a negative pressure gradient exists beyond the separation point, as it often does, there will be a reverse flow towards the separation point, all of which will produce a breaking away of the streamlines from the surface, leaving the surface between the two separation points, on either side of the body, in contact with air of random vortices and low pressure. Referring to Fig. 4, because of the vortices the pressure at n has failed to build up to the pressure at m (as it would have had the fluid been frictionless and without premature separation point), resulting in the creation of a downstream dragging force. This is characteristic of any body having a turbulent wake. Early turbulence in the

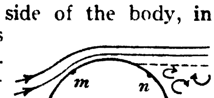

Fig. 4 Low-pressure wake.

boundary layer is desirable, so that the greater average momentum of boundary layer air can carry it against skin friction farther around the bluff surface, and so delay the separation point and narrow the turbulent wake. Thus the coefficient of drag for a sphere $\left(C \text{ of } Cq\frac{\pi d^2}{4}\right)$ is about .5 for laminar boundary layer and .1 for turbulent, with the transition occurring at a Reynolds number of approximately 300,000.

The applications of aerodynamics are varied and numerous, and stretch from scientific research to commercial design. Many of them are described specifically in this volume, and the reader is invited to consult the following: **Circulation, Airfoil, Boundary Layer, Stagnation Point, Stream Line, Drag, Lift, Vortex, High Lift Devices, Kármán Vortices, Downwash.** (F.T.M.)

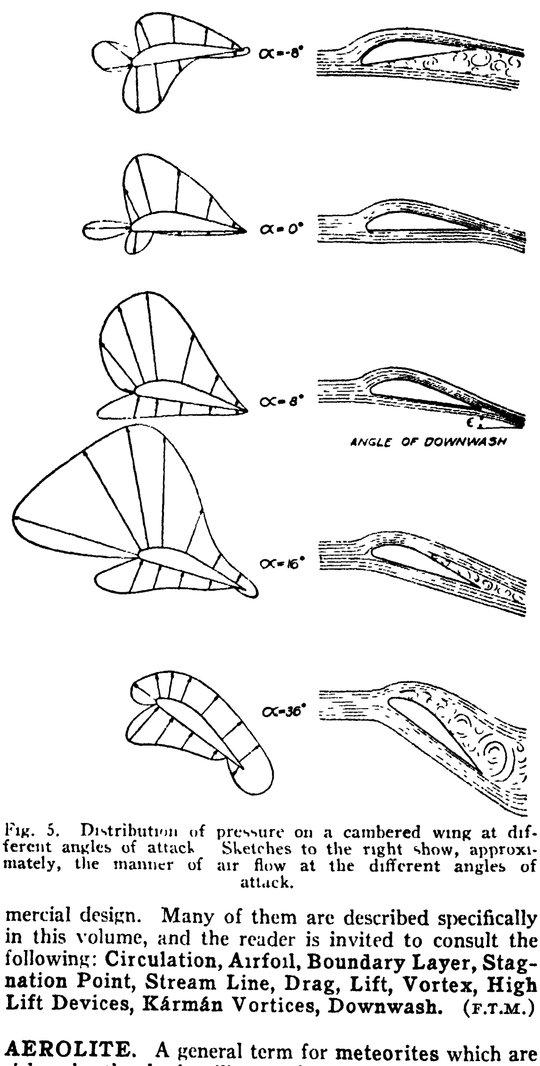

Fig. 5. Distribution of pressure on a cambered wing at different angles of attack. Sketches to the right show, approximately, the manner of air flow at the different angles of attack.

AEROLITE. A general term for **meteorites** which are richer in the basic silicates than in nickel and iron. (F.M.F.)

AERONAUTICAL ENGINES. An aeronautical engine is any engine which, by virtue of design or adaptation, successfully meets the special requirements of the propulsion of aircraft. These special requirements are:

1. Weight. Low weight per hp developed.
2. Reliability. This applies especially in aviation, but is not to be disregarded in aerostation (see **Aeronautics**).
3. Stamina. Aircraft engines must be able to deliver continuously at least 75% of their full power without overheating or excessive wear.
4. Frontal Area. A minimum frontal area should be presented to the windstream.
5. Rotative Speed. The rotative speed cannot be increased above about 2000 rpm without adding reduction gearing because of the poor efficiencies of **propellers** operated at high speeds.
6. Ability to continue functioning when placed in other than normal horizontal position, and when subject to accelerations as during acrobatic flying.
7. Compensation for changes of atmospheric conditions at altitudes equal to the highest altitude at which the airplane can be flown.
8. Balance. Freedom from shaking and vibrating forces.
9. Thermal Efficiency. This affects the amount of fuel that needs to be carried.
10. Ease of maintenance and overhaul.

It has not been possible to achieve the best in all these requirements in any single engine, but many available aeronautical engines exhibit an excellent combination of many of them. Owing to the comparative rarity of **airships**, the airship engine is here accorded only passing notice. The blimps are powered by the smaller stock airplane type engines, but special engines are usually designed and built for dirigibles.

One of the most important requirements of the airplane engine is the necessity for achieving all the other requirements with due regard to keeping the weight at a minimum. Generally speaking, reliability, stamina, balance, etc., are opposed to low weight per horsepower, so that the design of an aeronautical engine becomes a compromise between the other desirable features and weight. The low weights of today's engines are achieved by the use of special alloy metals, careful designing, and extensive testing. The larger engines will be higher per unit output than the smaller ones, because the weight of auxiliaries, such as magnetos, carburetors, and the like, does not vary directly in proportion to output, but is nearly as much in small engines as in large ones. The weight of large aeronautical engines is usually between 1 and 2 lbs. per hp. The smaller sizes weigh between 2¼ and 3¼ lbs. per hp. As there must be a horsepower for at least every 25 lbs. of airplane weight, it can easily be seen that the engine is no small part of the weight of an airplane. As a matter of fact, 25 lbs. per hp. would represent an airplane greatly underpowered, judged from modern standards. Fifteen pounds per hp. is more nearly an average figure for the small sportsman or trainer type of airplane, 10–12 lbs. per hp. for the high-speed transports, and as low as 6–7 lbs. per hp. for high-performance military airplanes. This requirement of lightness has led to the perfection of the internal combustion engine of the **Otto cycle** type as the leading aeronautical engine. While Diesel and steam types of prime movers both have successfully flown aircraft, and may become very important to the aircraft of the future, the gasoline engine is preeminent in this field at the present time. Its commanding position is principally due to its superiority in weight per horsepower developed. In many other points it is inferior, as it uses a type of fuel that has high fire and explosion hazard, it requires auxiliaries which are delicate and easily thrown out of adjustment, and suffers a loss of output at increasing altitude. These disadvantages, however, only serve to emphasize the importance attached to weight.

Reliability in the **Otto engine** may readily be secured, but usually only at the expense of increasing the weight, and to secure the maximum possible reliability, the weight would be prohibitive. Hence the aircraft engine cannot be entirely reliable, although manufacturers have been able to achieve remarkable results in this direction. Airplanes acting as public carriers should, for night schedules, be multi-motored, and able to maintain altitude with one motor out. This feature is of less importance in daytime flying, as the pilot, confronted with engine trouble, will usually be able to select an emergency field and land safely, an achievement prac-

tically impossible at night. The spark plug element of the ignition system is one of the less perfect components of an engine, but the whole electrical ignition system is such that it is deemed best to duplicate it, so common practice on standard engines is to have two spark plugs in each cylinder, and two independent sources of voltage to these plugs. It has not been expedient from the standpoint of cost or weight to duplicate all the auxiliary systems of the gasoline engine.

Unlike the automobile engine, which may operate over long periods of time at only 25–35% of full power output, the aeronautical engine must deliver its "cruising" power steadily, and be able to deliver full power for a period of several minutes' duration. The airplane engine is called on for a full power output during the period of take-off and climb to some altitude at which the pilot feels it safe to throttle back. The throttled power output, however, is rarely less than 65% full power for cross-country work, and it is not usually possible to maintain altitude in an airplane with the power output less than 50% of rated. For these reasons, a high degree of stamina, which involves special attention to the cooling and lubricating systems, as well as to the wearing parts, must be incorporated in aeronautical engines.

The parasitic drag of an aeronautical power plant is dependent on its cooling system. Between 25 and 35% of the heating units in the fuel must be passed through the cylinder walls in order to keep them cool enough, and this heat must ultimately be dissipated to the atmosphere. If this is done by extending the outside surface of the cylinder to form fins and moving an airstream across them, the more effective the cooling, the greater the parasite **drag** involved. If a liquid cooling medium is interspersed between cylinder and atmosphere, as is the case in liquid-cooled engines, the engine may be completely enclosed in a well streamlined fuselage or nacelle, but a radiator must be placed in the windstream at some point, and becomes a source of drag. The radiator resistance of very large engines is less than the drag of air-cooled engines of equivalent power, and hence the liquid-cooled engine is favored for high-speed, high-powered airplanes. Special low drag types of radiators have been employed on high-speed racing planes, where neither engine drag nor radiator drag can be tolerated. These surface radiators, however, are altogether too fragile and expensive to be considered for any other service than the special one of high-speed racing, wherein the working life of the aircraft may not extend beyond a test period and a record-breaking flight over a measured mile or similar short course.

A most serious defect of the internal combustion engine is its decrease in **volumetric efficiency** and developed power when it is supplied with air of decreasing density. Such is the case when an airplane climbs steadily. It eventually arrives at an altitude where the decrease in engine horsepower leaves no excess power over that required to maintain horizontal flight, and no further climb is possible. The **airplane** is then said to have reached its "ceiling." This ceiling varies upward from 10,000 feet above sea level, depending upon the horsepower, weight, and wing area of an airplane. It may be increased several thousand feet with a **supercharger.** Since flight at high altitudes (i e., stratosphere flight) holds forth much of promise for the aeronautical industry of the future, the supercharged internal combustion engine, or an external combustion cycle, such as the steam cycle, will be favored types.

The average thermal efficiency of the aeronautical engine is 25% at full rated power, and individual engines depart only slightly from this value. The gasoline tanks must hold sufficient gasoline to provide about .09 gal. for each horsepower used per hour.

Practically all cylinder arrangements that have been used for internal combustion engines are to be found in aircraft practice, but many of them are seldom seen. The more common cylinder arrangements are shown in Fig. 1. The radial arrangement of cylinders is probably used more than any other at the present time.

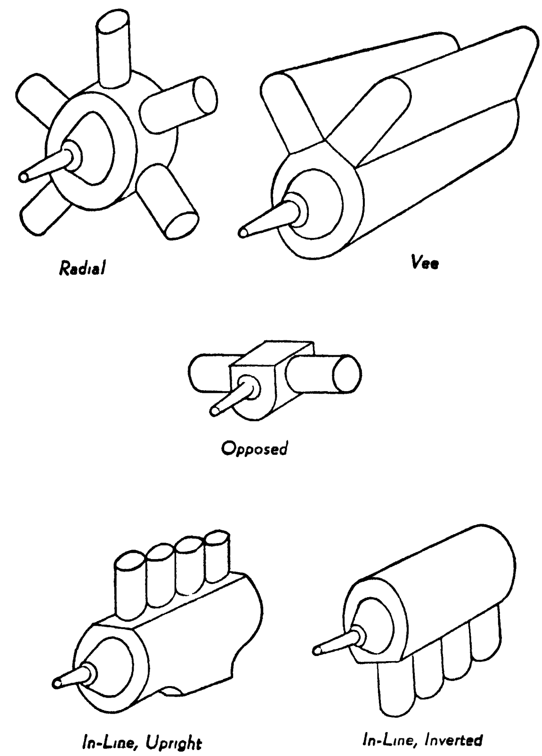

Fig. 1. Aeronautical engine cylinder arrangement.

The radial aeronautical engine is always air-cooled. In fact, one of the principal advantages of the radial arrangement is the presentation of each cylinder, individually, to the cooling airstream, whereas in-line arrangements, while presenting a lower frontal area, have problems of cooling introduced by the fact that only the front cylinder meets an undisturbed airstream. The radial engine has a short cylindrical crankcase to which are attached, with axes radial to the crankcase, cylinders to the number of 3, 5, 7, or 9. The cylinders are nearly evenly spaced around the circumference of the crankcase. The crankshaft, which passes through the center of the crankcase, has a single throw and is supported on two main bearings and one thrust bearing. The front end of the crankshaft protrudes from the crankcase and on it is mounted the propeller hub. Through gearing, the crankshaft drives the valve lifting cams, the magnetos, the oil pump, and many other needed accessories. A radial engine of the four-cycle type must be built with an odd number of cylinders because it fires on alternate cylinders, and the four-stroke cycle requires two full revolutions before all cylinders have fired Thus, in a seven cylinder engine, in which the cylinders are numbered consecutively 1, 2, 3, . . . 7, the firing order is 1-3-5-7-2-4-6. Radial engines using 6, 14 and 18 cylinders have been built, but they are really twin threes, twin sevens, or twin nines, and their crankshafts have two throws. Since some cylinders of a radial engine must project from the lower part of the crankcase, no integral oil sump is possible, but rather the oil is withdrawn from the lower part of the crankcase by a sump pump and delivered to an external oil tank where it is stored and cooled, and from which it is taken by the pressure oil pump and delivered back to the bearings and other parts of the engine. The piston and connecting rod arrangement is interesting in that there is one

master rod which bears upon the crankshaft, while the remaining cylinders have articulated connecting rods, that is, they bear upon pins in the big end of the master connecting rod. All this is clearly shown in Fig. 2, in which the cylinder having the master rod is vertical, a customary arrangement. Except for the connecting rods the cylinders are identical.

The in-line cylinder arrangement, in which the cylinders are mounted in a line over a crankshaft which has as many throws as there are cylinders, is used in both air- and liquid-cooled engines. For engines of equivalent output, the in-line engine tends to be heavier because of the longer crankcase and crankshaft, but presents a much lower frontal area and is more susceptible to streamlining than the radial type. Six cylinders in line, however, are about the maximum that can be successfully cooled, and these must be equipped with a special cowling containing air scoops and deflectors to direct cool air over the cylinders and to discharge heated air from the forward cylinders so it will not tend to heat those behind. In-line, air-cooled engines are frequently made inverted, that is, having the cylinders projecting downward from the crankcase. Advantages of improved forward visibility and high thrust center are secured by inverted designs. The upright engines may have self-contained oil sumps, but inverted engines must have external oil tanks.

Small 4- and 6-cylinder air-cooled engines are frequently made horizontally opposed. This type is excellent as a light plane engine. It rarely exceeds 150 hp., whereas the air-cooled in-line engine is found up to 500 hp., and the radial as high as 2200 hp., in stock models. The vee arrangement of cylinders is frequently used in multi-cylinder water-cooled engines, and occasionally in air-cooled engines. The present trend, however, is to employ liquid-cooled engines only in the larger powers.

The constant effort of aeronautical engine designers to reduce the weight per horsepower has not left much place for the commoner materials of construction, such as cast iron. While a few small air-cooled engines will have cast iron cylinders, standard practice in this field indicates the use of forged steel cylinder barrels, to which are attached cast aluminum alloy cylinder heads by bolting, screwing, shrinking, or combinations of these. Questions of cooling, volumetric efficiency, and manufacturing cost dictate the use of overhead valves in these engines, consequently the cylinder heads contain the ports, valve seats, and spark plugs. Aluminum bronze rings are inserted to form the valve seats as aluminum does not possess sufficient strength to resist the pounding action of the valves. Pistons are aluminum alloy, and connecting rods are duralumin or drop forged alloy steel. Crankcases are cast or forged aluminum, usually machined all over, while crankshafts are of special alloy steel, such, for instance, as nickel chromium steel. Valves offered difficult problems as they tended to warp, leak, pit, break, and stick under the severe service conditions of aeronautical engines. Engine manufacturers have, with the cooperation of parts manufacturers and metallurgists, succeeded so well in solving these problems that the latest engines produced satisfy, to a high degree, all the requirements mentioned in the introduction to this article. (See also **Gas Turbine, Rocket, Reaction Propulsion, Valve Gear, Carburetor Types, Ignition System, Otto Engine, Spark Plug, Airplane Engine.**) (F.T.M.)

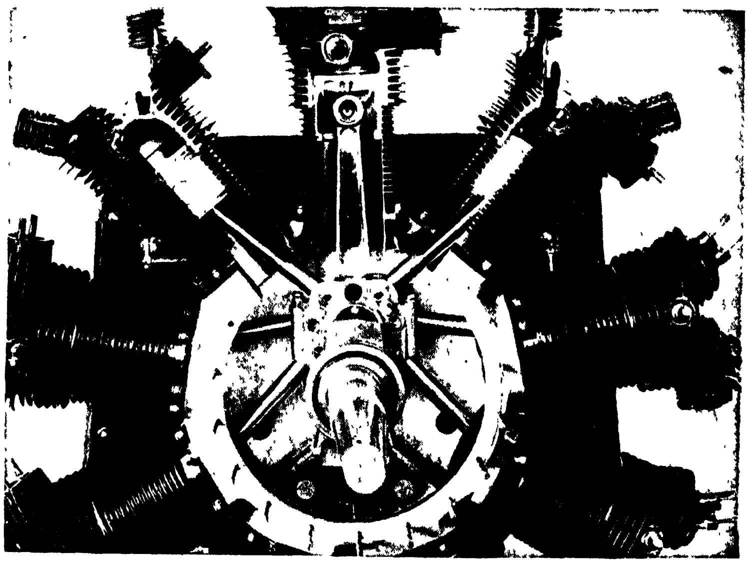

Fig. 2.

AERONAUTICS. Aeronautics encompasses all that pertains to the study, design, manufacture, maintenance, testing, and use of aircraft. Since the term aircraft includes any machine or device for navigating the air, aeronautics is seen to be a term embracing a broad field of human activity. One general method of aeronautical classification is based on the method of sustention of the aircraft, namely:

1. Aviation, where lifting is obtained from the dynamic action of air in motion relative to wings.
2. Aerostation, in which lift is obtained by the buoyancy of a volume of light gas.

Aviation is therefore that branch of aeronautics which pertains to heavier-than-air craft, such as fixed wing **airplanes, gliders, autogiros, ornithopters, helicopters.**

Aerostation is that branch of aeronautics which pertains to **airships,** free **balloons,** and captive balloons.

Not included in either of the above categories is the rocket type of aircraft.

The following outline will serve to give the reader an idea of the activities in the whole field of aeronautics.

1. Study of aircraft, theoretical and practical.
   a. Education in aviation schools and colleges Flying instruction, ground school work for mechanics and craftsmen, business and commercial studies, technological or engineering education.

   b. Research, in developing new aircraft types, improving present types, investigating meteorological conditions, etc.
      (1) Governmental agencies (Army, Navy, National Advisory Committee for Aeronautics).
      (2) Universities.
      (3) Manufacturers.
2. Design. Design of aircraft, landing fields, hangars, aircraft equipment, communication systems, etc. This activity is found mainly in factories manufacturing aircraft, but is also, to a lesser extent, carried on by individual experimenters and various government agencies.
3. Manufacture.
   a. Processing raw materials. Manufacturing of special alloy metals, selection and seasoning of wood, manufacture of finishing materials, extraction of helium, etc.
   b. Fabricating. Shaping raw materials to the final form in accordance with design drawings.
   c. Assembling. Building the finished aircraft, hangar, radio transmitter, etc.
4. Testing.
   a. Ground testing of materials, methods, engines, etc.
   b. Flight testing of the aircraft structure, of instruments, of power plants, of transport schedules, and of communication systems.
5. Maintenance, inspection, and repair of flying equipment, and of ground equipment.
6 Use.
   a. Military. Observation, bombing, pursuit, patrol, direct ground offense.
   b. Civilian. Non-commercial. For personal transportation, pleasure flying, and air racing
   c. Scheduled air transport. An important phase of the aeronautic industry, which acts as a public carrier of persons, mail, and cargo, on definite time schedules between specified points, and over specified routes, in so far as exigencies of weather conditions permit.
   d. Fixed base operation. Special for-hire charter trips, of both business and sporting nature.
   e. Miscellaneous.
      (1) Forest patrol.
      (2) Executive transport.
      (3) Advertising.
      (4) Freight transportation to otherwise inaccessible regions.
      (5) Map photography.
      (6) Crop dusting, etc.
7. Regulation and control. United States Civil Aeronautics Administration and State Aeronautical Commissions or Bureaus. Supervision of the aeronautical industry for the purpose of promoting general public safety against the hazards of aeronautical transportation, including:
   a. Setting up standards of design and construction of aircraft and other aeronautical equipment.
   b. Inspecting design and construction, and certifying equipment, i.e., licensing.
   c. Supervising the airworthiness of aircraft.
   d. Examining operating personnel, pilots and mechanics, for competence and physical condition.
   e. Developing and maintaining airways.
   f. Developing new and improved aeronautical equipment. (F.T.M.)

AERO-THREAD. **Screw Thread.**

AESCULAPIUS. The god of healing in ancient Greek mythology. (R.S.M.)

AESTIVATION. Summer dormancy, the antithesis of the more familiar **hibernation.** (A.W.L.)

AFRICAN CRESTED RAT. Mammalia, Rodentia. *Lophiomys.* A rare species of **rat** of northeastern Africa, related to the wood-rats of North America. (A.W.L.)

AFRICAN JUMPING HARE. Mammalia, Rodentia. *Pedetes.* A South-African species with large hind legs. (See **Rodentia.**) It belongs with the **jerboas** near the true mice and not with the hares as the name suggests. (A.W.L.)

AFRICAN LEMUR. **Galago.**

AFRICAN SLOW LEMUR. **Potto.**

AFTERBIRTH. The membranes and **placenta** expelled from the **uterus** a short time after the birth of the child. (R.S.M.)

AFTERGLOW. **Electrodeless Discharge.**

AGAMA. A large South African **lizard** of the genus *Agama.* (A.W.L.)

AGAMONT. A single-celled animal of a generation which reproduces asexually. (See also **Gamont.**) (A W.L.)

AGAR-AGAR. A gelatine-like substance which is prepared from various species of red **algae** growing in Asiatic waters. The prepared product appears in the form of cakes, coarse granules, long shreds, or in thin sheets. It is used extensively alone or in combination with various nutritive substances, as a medium for culturing **bacteria** and various **fungi.** It is sometimes recommended as a mild laxative. (R.M.W.)

AGARICS. Agaricaceae. Fungi. This family of **fungi** is probably better known than any other, since it contains most of the plants commonly described by the names toadstool and mushroom, which popularly and mistakenly denote poisonous and edible fungi, respectively.

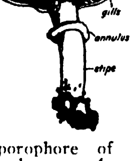
The Agarics are mostly fleshy fungi of that very definite structure, the familiar parasol-like toadstool This is composed of convex pileus or cap, usually supported on an evident stalk. The underside of the cap shows a series of radiating plates, or gills, which are formed in agaric fungi only, and so serve to separate them from all others. The two sides of the gills are covered with the microscopic spore-bearing bodies called basidia, which are club-shaped or cylindrical cells bearing **spores,** generally four each. Agarics vary in size from delicate species with a cap a millimeter or so in diameter, supported by a slender thread-like stalk, to massive forms twelve inches in diameter: the larger species form millions of spores.

The spores float in the air for considerable distances, and finally come to rest on some solid substance Should this be favorable for germination, the spore puts out a slender tube, which elongates rapidly and penetrates the substratum, from which it absorbs substances necessary for its continued growth. Gradually this thread-like body, known as the mycelium, spreads through extensive masses of substratum, branching frequently as it does so.

Finally there is accumulated in the mycelium a supply of reserve food sufficient for fruiting: then, if atmospheric conditions, such as moisture and temperature, be suitable, the familiar toadstool appears, it being only the reproductive stage of the fungus. Its rate of growth is often phenomenal, as is also the force it may exert in its growth. Seemingly delicate bodies not only break open the hard-packed surface of the ground, but also may push aside pebbles of considerable weight. Not infrequently whole rings of toadstools appear in a field, springing to maturity in a single night—these are the familiar **fairy rings,** resulting from the growing outward from a com-

mon source of the unseen mycelium and not from the dancing of fairy forms.

When the young fruit-body first comes up it is completely enclosed in a membranous skin known as the velum. As enlargement continues this skin is broken. Often traces of the velum remain in the form of flakes on the upper surface of the cap, and as a ring or annulus around the stalk. Attempts have been made to find in these characteristics a means for separating the edible from the poisonous species. However, no reliable distinction is found here. Actually, unless one is absolutely sure of the identity of a given species, the only safe rule is complete abstinence. Classification is based on the color of the spore-masses, and also the determination of the way in which the gills are attached to the stalk, the color changes shown as a cut or broken surface dries, and various other means.



Sporophore of a mushroom, *Agaricus campestris.*

A few species of Agarics, notably *Agaricus (Psalliota) campestris,* are extensively cultivated, and justly esteemed as food. Other species are violently poisonous, particularly species of the genus *Amanita.* Yet certain Siberian people use *Amanita muscaria,* a poisonous species, to produce a form of intoxication. Another common mushroom, the Inky-cap, a species of *Coprinus,* has been used as a writing fluid, the substance of the toadstool breaking down into a fluid mass containing vast numbers of black spores. (See **Basidomycetes.**) (R.M.W.)

AGATE. Agate is a variety of **chalcedony** whose variegated colors are distributed in regular bands or zones, in clouds or in **dendritic** forms, as in moss agate.

The banding is often very delicate with parallel lines of different colors, sometimes straight, sometimes undulating or concentric. The parallel bands represent the edges of successive layers of deposition from solution in cavities in rocks.

As agate is an impure variety of quartz it has the same physical properties as that mineral. It is named from the river Achates in Sicily where it has been known from the time of Theophrastus.

Agate is found in many localities; India, Brazil, Uruguay and Germany are notable for fine specimens.

Onyx is a variety of agate in which the parallel bands are perfectly straight and can be used for the cutting of cameos. Sardonyx has layers of sard (red carnelian) alternating with lighter-colored layers of onyx. (E.S.C.S.)

AGAVE. Amaryllidaceae. A large genus of plants, particularly abundant in Mexico, in which the thick rigid leaves form a basal rosette from the center of which rises the tall flower stalk. Because of the time required to store sufficient food reserves for flowering, certain species, notably *Agave americana,* are called **century plants** from the belief that they flower but once a century, actually flowering may occur in from 5 to 50 or more years. Once started, the flower stalk develops very rapidly, requiring immense quantities of sap. In Mexico, the flower stalk is cut off early in its formation and the stump scooped out to form a cup into which quantities of sweet sap exude. This sap is collected and fermented to form pulque, a strong drink with an unpleasant odor. Distilled pulque gives a more potent drink, mescal. From the leaves of several species, particularly *Agave sisalana* and *A. fourcroydes,* are obtained fibers. These fibers occur as **sclerenchyma** sheathes surrounding the vascular bundles in the leaves. To obtain the fibers, the leaves are cut off and the spiny tip and margin removed. Machines then heat and scrape the leaves and wash them until the clean fibers are obtained. These are then dried either in the sun or by artificial heat, and are ready for export under the name of sisal or henequen, according to the species from which they were obtained. Many species of Agave are cultivated for their ornamental value. (R.M.W.)

AGE OF THE EARTH. Chronology.

AGE-HARDENING. Precipitation Hardening.

AGGLOMERATE. A term proposed by Sir Charles Lyell in 1831 for coarsely graded volcanic ejectamenta similar in appearance to ordinary **conglomerates** or **breccias.** An extremely thick and widespread accumulation of so-called agglomerates occurs on the borders of the Yellowstone Park. These deposits, however, include numerous beds of water-laid pebbles, gravels and sands, the latter containing fossil plants of early **Tertiary** age. (R.M.F.)

AGGRADATION. In geology, the deposition of sediment by a river in its valley. (See also **Alluvial Fans.**) (R.M.F.)

AGGREGATE. The solid particles which form the major portion of the volume of **concrete** are called aggregate. The aggregate may be classed as fine or coarse depending upon the size of the individual particles. The specifications for the concrete on any project will give the limiting sizes which will distinguish between the two classifications. Fine aggregate generally consists of sand or stone screenings while crushed stone, gravel, **slag** or cinders are used for the coarse aggregate. The aggregate should be strong, clean and free from clay or organic matter since the strength of concrete depends upon the strength of the individual particles as well as the efficiency of the cement as a binder. (C.W.C.)

AGGREGATE GLANDS. Silk glands of **spiders** which produce the viscid spiral lines of the web. (A.W.L.)

AGONIC LINE. The line of no magnetic variation (declination) or deviation of the compass from true north. (See also **Geomagnetism** and **Isogonic Chart.**) (R.M.F.)

AGOUTI, AGUTI. Mammalia, Rodentia. Large **rodents** of the genera *Dasyprocta* and *Myoprocta* found in Central and South America and the West Indies, where they live chiefly in the forests. They are hunted for their flesh. (A.W.L.)

AGRANULOCYTOSIS (Agranulocytic Angina, Malignant Neutropenia, Granulocytopenia). A syndrome characterized by a marked decrease in white blood cells, particularly those of the granulocytic series (see **Blood**). The clinical picture is one of high fever and ulcerative lesions of the skin and **mucous membranes** which may become gangrenous. The mortality is high. There is an idiopathic type whose etiology is unknown, but the majority of cases are traceable to a toxic reaction to any of a number of drugs. Chief among these are aminopyrine, a common pain-relieving drug, arsenicals, gold salts, dinitrophenol, benzol and certain of the **sulfonamides,** particularly sulfanilamide. Treatment is supportive. (D.M.H.)

AGRICULTURAL CHEMISTRY. Agricultural chemistry is that branch of the science of chemistry which deals with the chemical processes connected with the growth of plants and animals, and the preparation of these and their products for market. Since plants are dependent upon air and soil, and upon water and climate for their growth, these are matters of prime importance in connection with crop cultivation. The maintenance of proper soil involves the study of the various chemical types of plant food, of fertilizers, and the effect of small percentages of various elements. The cultivation of

plants also necessitates battling against injurious pests and diseases. The preparation of plant and animal product calls for examination of preparation methods as such, for example, in the case of milk products, butter, cheese, lactose, casein, and of the storage and transportation conditions, for example, meats, eggs, fruits, vegetables. (See **Soils: Fertilizers; Reactions Involving Recombination of Ions, Hydrogen Ion Concentration; Poisons; Foods; Photosynthesis; Biochemistry.**) (R.K.S.)

AGUE. Recurrent chills and **fever,** usually of **malarial** origin. (R.S.M.)

AI. **Sloth.**

AIGRETTE. The tuft of slender feathers found on the back of the **egret** during the breeding season. (A.W.L.)

AILANTHUS. Simarubaceae. Tree of Heaven, or Tree of the Gods. A genus of trees having large pinnate leaves, small flowers and winged fruit One species, *Ailanthus glandulosa,* a native of China and Japan, has been extensively introduced into cities in the eastern United States, because of its ability to withstand the gas and smoke of the city, and is often found growing to large size in most unlikely habitats. An objectionable feature is the unpleasant odor of the male flowers. (R.M.W.)

AILERON. The aileron is one of the three **aerodynamic** surfaces of an **airplane** which are variable in attitude at the will of the pilot, and the purpose of which is to provide the required degree of maneuverability of the aircraft. The aileron is that surface which produces rotation about the longitudinal axis of the fuselage. This motion is known as roll, and is necessary to correct other rolls produced unintentionally, as by gusts, and is also employed to accomplish such maneuvers as banks or sideslips, both of which require a certain degree of roll executed under the control of the pilot.

The conventional type of aileron is a flap attached to a portion of the trailing edge of the **wing,** usually towards the extremities. This flap is rotatable around its forward axis, upwards and downwards, and in effect changes the **camber** of the airfoil. The result is a change of pressure on the wing much greater than that which could be obtained by pressure on the aileron alone. The principal defect of this type of aileron is that it becomes relatively ineffective when, for safety's sake, it is needed to be most effective; that is, when the airplane approaches the stall, or is stalled With adequate control of roll during a **stall,** many serious accidents involving the tailspin could have been avoided. Except for this point, the trailing edge aileron is highly satisfactory. Its aerodynamic efficiency, simplicity, reliability, freedom from flutter, and balance are better than in other types, such as wing tip ailerons, spoiler ailerons, etc., which in consequence have not been widely accepted. (F.T.M.)

AIMLESS DRAINAGE. Type of drainage or stream pattern which occurs in low swampy lands. Particularly characteristic of glaciated regions of low relief. (R.M.F.)

AIR. The term air is frequently used as synonymous with **"atmosphere** of the **earth"** and it is in that sense that we shall use it here. The earth's atmosphere consists of a vast body of gases, vapors, and suspended matter of total mass about 5.1×10^{15} tons, or somewhat less than one-millionth part of the total mass of the earth. The height to which the air extends can be estimated only by the effects which it produces. On purely theoretical grounds, since according to the **kinetic theory** of gases some molecules attain velocities great enough to escape not only from the earth but also from the **solar system,** we may say that the atmosphere of the earth extends out into space until it mingles with the interstellar gases of the **milky way.** The **twilight** arch has been observed to a height of about 45 miles, **meteors** become visible about 75 miles, on the average, above the surface of the earth, and **aurorae** have been observed up to more than 600 miles.

Most of our knowledge of the composition of air is based upon samples that have been taken at the surface of the earth. There air is composed chiefly of oxygen and nitrogen (and this is probably true to a height of 70 kilometers). Air also contains a variable proportion of water vapor, and small quantities of other gases. In many engineering calculations, air is considered to be composed only of nitrogen and oxygen, and the proportions assumed for such calculations are, by weight, 76.8% nitrogen and 23.2% oxygen; and, by volume, 79.1% nitrogen, and 20.9% oxygen. A more detailed analysis of air (without taking into consideration the variable amount of water vapor) is given below:

AVERAGE COMPOSITION OF AIR *

(At, or near to, the surface of the earth)

Substance	Percentage (By volume of dry air)	Percentage (By weight of dry air)
Nitrogen	78.09	75.54
Oxygen	20.93	23.14
Argon	0.93	1.27
Carbon Dioxide	0.03	0.05
Neon	0.0018	0.0012
Helium	0.0005	0.00007
Krypton	0.0001	0.0003
Hydrogen	0.00005	0.000004
Xenon	0.000008	3.6×10^{-5}
Ozone	0.00005	1.7×10^{-6}

* Paneth, *Quart J R. Met Soc.* **63,** 436 (1937).

Carbon dioxide is produced by the combustion of **carbon-containing fuels** and from the decay of organic matter. Its concentration in the air would be much greater if it were not consumed by vegetation in the process of **photosynthesis,** by which oxygen is liberated In this way, the steady addition to the atmosphere of carbon dioxide by the combustion of fuels, and by the breathing of men and animals, is counteracted, and the oxygen-carbon dioxide ratio of the air is maintained.

The content of water vapor in the atmosphere varies greatly in amount, depending upon the locality, the season of the year, and the hour of the day, due to local

WATER VAPOR CONTENT OF NATURAL AIR

(Monthly Averages at Pittsburgh, Pa)

Month	Average Temperature (°F)	Concentration of Water in Air (Grains per cu ft)	Volume of Water (Gallons per hour at air rate of 20,000 cu ft. per min)
Jan.	37.0	2.18	87
Feb	31.7	1.83	73
Mar	47.0	3.40	136
Apr	51.0	3.00	120
May	61.6	4.80	102
June	71.6	5.04	238
July	70.2	5.60	224
Aug..	73.6	5.16	206
Sept.	70.4	5.68	227
Oct.	56.4	4.00	160
Nov.	40.4	2.35	94
Dec.	36.6	2.25	90

and general states of the weather. On account of the great importance, meteorologically and industrially, of the amount and variation of water vapor in the atmosphere, extensive studies have been made by weather bureaus and various industries.

The amount of water vapor contained in the air may be expressed as the relative humidity, which is simply the fraction actually present of the amount of water required completely to saturate the air. The amount of water necessary to saturate 1 lb. of dry air is shown by the following table:

WEIGHT OF WATER NECESSARY TO SATURATE ONE POUND OF DRY AIR

Temperature (°F.)	Weight of Water (Lb.)
40	.00520
45	.00632
50	.00765
55	.00920
60	.01105
65	.01322
70	.01578
75	.01877
80	.02226
85	02634
90	.03108
95	.03662
100	.04305
105	.05052

The temperature of the air decreases, in general, with altitude up to about 10 or 12 kilometers within the layer, known as the "troposphere," in which convection currents and storms occur (see **Winds**). Above this is the "stratosphere," a region of unknown height within which a uniform temperature of about −55° C. (−67° F) obtains, and in which there are no clouds, little wind, and no storms. Nearly all of the water vapor and dust are in the lower half of the troposphere; the stratosphere being very clear and excessively dry (see **Humidity**).

The various data cited above on the composition of the air are based upon samples taken at or near the surface of the earth. However, it is thought that at higher altitudes, notably above 70 kilometers, there is a marked increase in the concentration of the lighter gases, and it is believed that whatever air exists above 100 kilometers consists largely of hydrogen and helium. It is also thought that there is more ozone in the stratosphere than near the earth, and that it is due to the action of **ultra-violet** radiation on oxygen. Through some agency, perhaps **cosmic rays** or else **electrons** from the **sun**, the upper atmosphere is much more highly ionized than the lower (see **Ionosphere**). The earth's negative charge and the electricity in the upper atmosphere give rise to a vertical potential gradient, amounting to about 1.1 volts per cm. at the surface, but rapidly diminishing with altitude (see **Aurora Borealis** and **Lightning**).

By means of instruments carried up by sounding balloons and from other sources of information such as, for example, the pioneer stratospheric flights, it is known that the atmosphere varies greatly with altitude in many respects such as (1) density, (2) pressure, (3) temperature, (4) motion, (5) composition, (6) electrical condition, and a number of other characteristics. The density, of course, is determined by the composition, pressure, and temperature. The pressure decreases with increasing altitude as is shown in the following table.

The standard density of air at 32° F. and 14.7 lbs. pressure is .081 lb. per cu. ft. Its gas constant is 53.4 cu. ft. per °F., and its composite molecular weight is 28.84. (See **Atmosphere.**) (F.T.M., R.K.S., L.D.W., W.K.G., P.E.K.)

VARIATION OF AIR PRESSURE WITH ALTITUDE

Altitude (Ft.)	Pressure (In. of Mercury)	Pressure (Lbs. per sq. in.)
Sea Level	29.92	14.7
1,000	28.86	14.2
5,000	24.89	12.2
10,000	20.58	10.1
15,000	16.88	8.3
20,000	13.75	6.8
25,000	11.10	5.4
30,000	8.88	4.4
.	. . .	.
50,000	3.44	1.7

AIR-BLADDER. A pouch found in some fishes (**Pisces**), derived from the gut and filled with a mixture of gases, chiefly oxygen and nitrogen. It regulates the buoyancy of the body. Embryological development and structural relationship indicate a common evolutionary origin for the air-bladder and lungs. (A.W.L.)

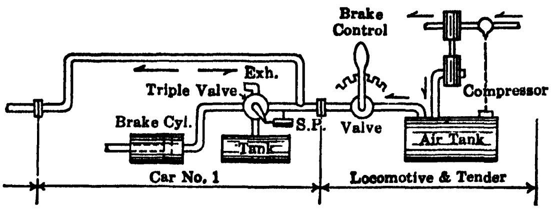
AIR BRAKES. This could refer to air-operated mechanical brakes, or to surfaces whose aerodynamic drag provides a retarding force, such as the fan-type dynamometer.

Airplanes which may be expected to make very steep and prolonged dives are fitted with air brakes to limit the maximum diving speed. Dive bombers furnish the principal example of this. They need to approach their target at high altitude for safety from hostile gunfire, then dive on it almost vertically. The speed during the dive could rise to unsafe magnitude for an aerodynamically "clean" airplane. To control the terminal velocity in a dive, these aircraft have movable surfaces resembling large flaps (see **High Lift Devices**) which can be lowered, that is, set at a sharp angle to the wing chord, during a dive. But whereas flaps are designed to increase the maximum lift coefficient, and increased drag is incidental, air brakes are designed to produce as much drag as possible, hence are often perforated to assist the production of a turbulent wake.

Passenger automobiles and light trucks have **brakes** actuated by foot pedal pressure through the medium of mechanical or hydraulic linkage. The magnitude of brake pressure required is low enough so that the moderate mechanical advantage of these brake systems is adequate. Automotive buses, large trucks and truck-trailer vehicles are not readily and safely controlled with the aforementioned brakes, so frequently have an air brake system. This is generally a pressure system. A small engine-driven air compressor keeps a storage tank charged at moderately high pressure. The brake pedal operates a valve which admits the high-pressure air to one side of a diaphragm. Resultant distortion of the diaphragm furnishes a powerful force to operate either a mechanical or hydraulic brake system.

The safety of railway transportation is guarded by air brakes. In 1872 George Westinghouse patented his famous railway air brake which, with improvements made from time to time, has become the standard railway braking system. This air brake system applies the brakes when the air pressure is lowered. Air pressure is thus a force to release brakes and any accidental breakage of the air lines, including car-to-car couplings, will result in application of the brakes.

The elements of this air brake system will be described with reference to the accompanying figure. A steam-driven compressor on the locomotive is governed to maintain a constant air pressure in the locomotive storage tank, say about 90 lbs. per sq. in. The air brake line connects this tank with a "triple valve." This is a servo-piston-operated valve with openings to the train air line, to a car storage tank, to the brake operating cylinder, and to the atmosphere. When the brakes are



Railway air brake system.

off, line pressure is charging the car tank and the servo-piston has the triple valve turned so as to connect the brake cylinder with the atmosphere. To apply the brakes line pressure is relieved by operation of the brake control lever, whereupon the triple valve is turned to admit car tank air pressure into the brake cylinder.

This simple system has been considerably modified in practice as longer and heavier trains were formed. The need for uniform brake application along the length of the train, and of a graduated energy absorption by the wheel brakes, have required the addition of compensating elements. Some train systems are electropneumatic in nature. (F.T.M.)

AIR CHAMBER. Pumps.

AIR COMPRESSION. The compression of air by mechanical means, and the raising of it to some desired pressure above that of the atmosphere, is effected, usually, by an approximate adiabatic change of state. The cycle of operation of an air compressor of the piston and cylinder form is briefly as follows Beginning with the piston ready to start on the compression stroke, the piston compresses the air until the pressure rises to slightly above the discharge pressure, when the spring-loaded discharge valve opens and the remainder of the compression stroke is a delivery of the compressed air through the discharge valve at approximately constant pressure. At the end of the compression stroke, the discharge valve returns to its seat, but there is a small amount of high-pressure compressed air retained in the **clearance** space between the piston and the end of the cylinder. On the suction stroke of the piston this clearance air must first expand to the suction pressure before the spring-loaded inlet valve opens. The remainder of the suction stroke is then the induction of the air to be compressed in the cylinder. At the end of the suction stroke the inlet valve returns to its seat, and the piston is ready for another compression stroke.

If the ideal compression were possible, it would be represented by the following equation showing the relation between pressure and volume:

$$PV^{1.4} = \text{a constant}.$$

A compression of this nature may heat the air to temperatures which would interfere with reliable action of an air compressor and introduce lubrication dfficulties, were there no provision for cooling the cylinder walls. Therefore, in compressors we find the cylinders to be externally finned or water-jacketed so that sufficient cooling is secured to keep the temperatures from becoming excessive. The extraction of heat from the cycle in this way modifies the conditions of compression from the ideal to some change more nearly represented by

$$PV^n = C,$$

in which n usually lies between 1.35 and 1.4. The ratio of the temperature before and after compression is expressed by the following equation, the temperatures being degrees Fahrenheit absolute.

$$\frac{T_2}{T_1} = \left[\frac{V_1}{V_2}\right]^{n-1}.$$

In compression to high pressures, the temperature rise may be too great to permit the compression to be carried to completion in one cylinder, even though it is cooled as mentioned above. In high-pressure compressors, the compression is carried out in stages, with a partial increase of the pressure in each stage, and cooling of the air between the stages. Two- and three-stage compression is very common where pressures of 300–1000 lbs. per sq. in. are needed.

The volume of clearance air should be made as small as possible in order to improve the **volumetric efficiency** of the compressor, since the clearance air must expand to the suction pressure before the cylinder can begin to be charged.

The mechanical construction of air compressors varies with the amount of compression required. Piston and cylinder compressors are usually employed for the highest pressures. In small sizes these are frequently single-acting, but are made double-acting in larger sizes. High compression pressures also may be produced by centrifugal action. (See **Air Compressor.**) Light pressures, such as are required in draft and ventilating systems, are obtained most economically by the use of fans of the centrifugal or propeller type

There is a type of compressor intermediate between the fan and the piston types. It is the rotary compressor or **blower,** which, operating by displacement, produces a positive air pressure, and, at the same time, is a compressor in which there are no reciprocating parts.

The compression of air and other gases may also be secured by the employment of steam jets if an admixture of vapor in the compressed gas is not undesirable. High-pressure steam is blown through nozzles which create a high-velocity jet. The gas to be compressed is led into the regions about the nozzle discharge where it is entrained in the steam jet. The mixture then travels into a diffuser for compression and attendant velocity reduction Although the compression thus achieved is of limited magnitude, staging the compression in a series of nozzles, with intermediate coolers for partial condensation of vapor, allows moderate compression ratios to be achieved. (F.T.M.)

AIR COMPRESSORS. *Reciprocating.* A common type of air compressor is the piston and cylinder compressor in which a reciprocating piston positively displaces the air from a cylinder during its discharge stroke Compressors for charging tanks of air used to inflate pneumatic tires at the numerous automotive service stations are of the reciprocating type Being of small capacity they are generally single acting and air cooled (by exterior fins) since those features are common in small compressors. Larger compressors, unless for extremely high pressure, are usually double acting and frequently cooled by water jackets. One or two cylinder arrangements are conventional, with a tendency to secure large capacity by increased bore and stroke rather than by multiple cylinders. Pistons are reciprocated by a crankshaft and connecting rod mechanism commonly deriving motion from the driving source by belt Valves are spring-loaded to open upon slight differential pressures

The compressor cycle is shown in Fig 1. The discharge stroke which begins at A builds up the pressure to B where it exceeds the receiver pressure sufficiently to

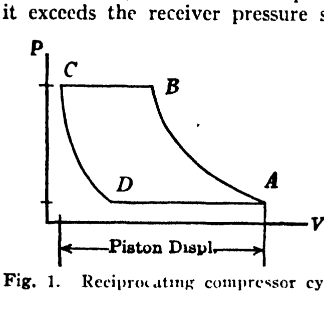


Fig. 1. Reciprocating compressor cycle.

open a discharge valve. Discharge then takes place at a constant control pressure from B to C. The volume C is the clearance volume of the compressor. The air in the clearance volume must expand to D during the suction stroke before the inlet valve will open. Thus the volume of air drawn in per stroke is only that from D to A. Obviously the compressor should have as small a clearance as possible in order to obtain good volumetric efficiency, especially at high discharge pressures. Small compressors may be operated with high compression ratios (8–12) if desired because cooling is more effective in small cylinders and mechanical strength is readily provided. Large volumes compressed to ratios exceeding 4 will need a multi-stage compressor to permit cooling between stages and to lessen the structural loads on the large first stage cylinders.

Rotating. Rotating compressors may be subdivided into four classes, known as fans, blowers, centrifugal compressors and turbo-compressors.

Fans are limited to low pressures where compression is negligible but large volumes are delivered.

Blowers are defined as machines for compressing air at pressures up to 35 lbs. per sq. in. gauge Centrifugal and turbine type compressors may be built to deliver high pressures by providing sufficient stages; however, reciprocating compressors are commonly employed for pressures exceeding 50 lbs. per sq. in.

Centrifugal Compressor. A rotating impeller mounted in a casing and revolved at high speed will cause a fluid which is continuously admitted near the center of rotation to experience an outward flow and a pressure rise due to centrifugal action.

Assume that an impeller with radial blades of depth $r_2 - r_1$ is revolving at a speed of ω radians per minute. This is illustrated in Fig. 2 Consider that a compressible

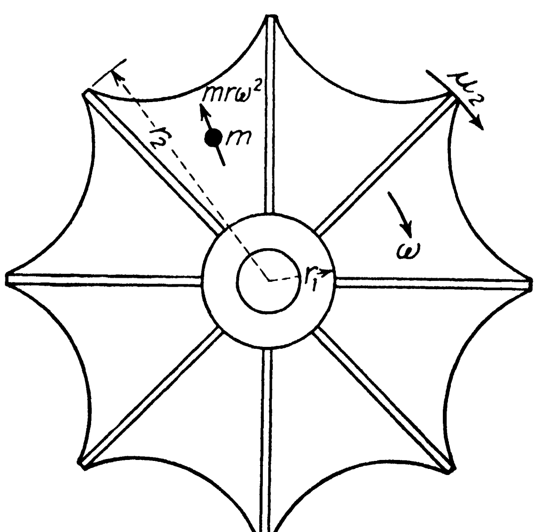

Fig. 2. Impeller for centrifugal compressor.

fluid (a gas) is admitted at the center and flows into the impeller radially. Relative to the impeller blades it has an outward radial flow, finally emerging with some absolute velocity v_2 which is partially diffused into pressure. In addition a pressure gradient must exist to balance the sum of all the incremental $mr\omega^2$ inertia forces arising from the inward acceleration $r\omega^2$ given each particle of the fluid. The interrelation of r, ω, P, can readily be developed by considering the power required as (1) that necessary for the thermodynamics of compression, and (2) that which would account for the action of the impeller in effecting certain momentum changes on the fluid.

Without detailing the algebraic procedure, it may be stated that the ability of an impeller to raise the fluid pressure is expressed by the ratio of discharge to inlet pressure, i.e., P_2/P_1

$$\frac{P_2}{P_1} = \left[1 + \frac{\eta z u_2^2}{gRT_1}\right]^{\frac{1}{z}}.$$

g = 32.2.
R = 53.4 for air.
z = A gas coefficient, about 0.286 for air.
T_1 = Inlet temperature, degrees Rankine.
η = Energy coefficient. This would be 1.0 if the flow through the impeller were non-turbulent and frictionless. Typically, η = .75 to .85.
u_2 = Impeller rim velocity, ft. per sec.

For pressure ratios higher than can be obtained from the action defined above, several impellers may be mounted on the same shaft and enclosed in a compound casing with passages arranged to lead the output from one impeller to the "eye" of the next. This multi-staging principle is used to produce pressures above the capability of a single impeller compressor. Multi-stage compression may have cooling between the stages so the overall compression may be more isothermal than adiabatic. If compression were isothermal

$$\frac{P_2'}{P_1} = e^{\frac{\eta u^2}{gRT}}.$$

(See also **Supercharger, Airplane Engine.**)

Turbo-compressors. This is a multi-stage **axial-flow** compressor, so called because of the resemblance, in action, to a reversed turbine. Fig. 3 shows a turbo-com-

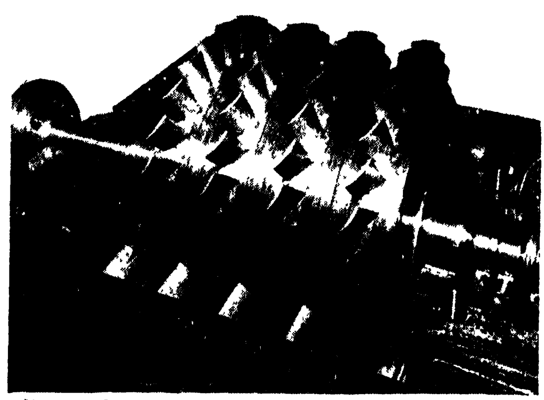

Fig. 3. Turbo-compressor rotor. (*General Electric Co.*)

pressor, while Fig. 4 illustrates the compressing action. Air flows over a set of stationary airfoils (arranged circumferentially as fixed blading, with an angle of attack α. As the airfoil **aspect ratio** is small, the **downwash** created is considerable. Downwash turns the air stream through angle ϵ, which results in a flow channel

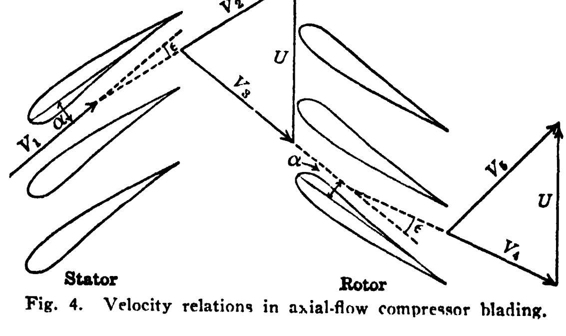

Fig. 4. Velocity relations in axial-flow compressor blading.

of increasing cross section. The diffusion thus effected slows down the air velocity to V_2 and increases pressure. The moving airfoils (rotor blades) receive this air stream at V_3 as a result of the vectorial combination of air stream velocity V_2 and blade speed U. Relative to the moving airfoils the downwash again causes a diffusion of velocity and another increase of pressure. The relative velocity V_4 leaving the moving blades produces an absolute final velocity of V_5 because of blade motion. Suitable combinations of U and α enable V_5 to duplicate V_1 and permit a similar following stage. The blade height in the following stage is decreased because of the smaller specific volume of the compressed air. Increasing α will increase the pressure rise without much decrease in volume. The turbo-compressor should be designed for conservative α's for two reasons. First, an operation near the stalling angle would be hazardous as small variations of α might occur which could **burble** the airfoils and cause an unstable, rough, or even hazardous condition to exist. Secondly, turbo-compressors may be employed under conditions where utmost efficiency is imperative (as in gas turbine power units) and α should create the optimum favorable balance between good downwash and minimum turbulent airfoil wake. Turbo-compressors have been built with energy efficiencies as high as 85%. They may be operated effectively at high speeds, i.e, 5000–10,000 rpm. (F.T.M.)

AIR CONDITIONING. Air conditioning is the artificial treatment of air in buildings to render the living conditions of persons within the building more comfortable and healthful, or to ensure better conditions for the production and storage of materials. Complete air conditioning involves adjustment and control of the following operations performed on the air supply of a building

1. Heating or cooling.
2. Humidification or dehumidification.
3. Ventilation.
4. Cleaning.

While portions of this complete program of conditioning were often used in past years, it has only been recently that the importance of complete air conditioning has been fully understood. That a change of air in a room has beneficial effects is quite generally understood and the ventilation of buildings has been a subject of considerable study Although it is quite obvious that dust and obnoxious fumes have no place in either industrial or domestic rooms, little has been done towards the filtering of air supplies. One new and important fact brought out within recent years has given great stimulus to more scientific handling of the air conditioning problem It is that, in addition to temperature and air movement, the relative **humidity** is a very important factor in determining the comfort of the occupant of a room Experimental research of the American Society of Heating and Ventilating Engineers indicated that air conditions which yielded equal degrees of warmth to human subjects plotted as straight lines on the common psychometric chart. These lines are called "comfort lines" The meaning of this fact is that a person may feel equally comfortable at two different temperatures, provided the humidity of the air at these two temperatures differs by the proper amount. The reason for the influence of humidity on comfort is that the nearer to a completely saturated state the air in a room becomes, the less tendency there is for evaporation to take place from the body. This evaporation plays no small part in determining hot weather comfort, and is a factor in surface cooling of the skin. On the other hand, in cold weather the atmosphere in an artificially heated room is very likely to prove deficient in moisture unless some special means for increasing the moisture content is provided. Some physicians believe that failure to humidify properly the air within heated buildings is an important contributing cause of the common cold during the winter season.

Complete air conditioning, then, will involve the following equipment. a ventilating system for giving motion and circulation to the air; a furnace or heater to raise it to proper temperature in cold weather; a refrigerator, or cooler, to temper it for hot weather comfort; a humidifier, or dehumidifier; an air washer, or filter. This complete service is frequently applied to industrial buildings, theaters, auditoriums, etc., but has not been employed to any appreciable extent in homes. One reason for this, of course, is the cost of such equipment for the average home. Another is lack of information on the benefits realized from an air conditioning installation; another, the widespread use of vapor or hot water heat, which is not readily converted to an air conditioning system.

It is interesting to note the reversion to the once obsolete warm air heating system, on the basis of its adaptability to partial or complete year-round air conditioning. The warm air heating system, once discredited as obsolete and inferior to other types, is returning to a position of some considerable importance through the employment of positive fan-created air circulation—eliminating many real defects in the gravity system—and the use of thermostat-operated automatic controls preventing fluctuations of temperature. Moisture can be added to the air at the furnace in the winter time, and to the required degree. The same system may be employed in the summer time, either with refrigerating coils in the return circuit, or with water sprays, or simply with the induction of air from without the building. Under any of these operating conditions, of course, the air passes through filters for the removal of dust.

Just as the air conditioning of industrial and public buildings has proven to be practical and profitable, so will, in all probability, air conditioning be an important feature in the new homes of the future. (F.T.M)

AIR GAP. This term is commonly used in connection with various **magnetic circuits** and denotes a gap left in the magnetic material In the construction of various **chokes** and **transformers** used in communications circuits a short gap is usually left in the core material to prevent the material being saturated by the d c. which often flows in such circuits. (See **Amplifiers** and **Power Supplies.**)

In rotating electrical machinery the rotating part of the magnetic circuit must, of course, be separated by a gap. In these machines this gap is kept as small as consistent with adequate mechanical clearance. In most instances the gap introduces no desirable electrical or magnetic characteristics and necessitates the application of additional electrical energy to overcome its **reluctance.** (L.R.Q.)

AIR HUNGER. Breathlessness or craving for air when insufficient **oxygen** is supplied to the **tissues** of the body. (R.S.M.)

AIR LIFT. An air lift is a water pumping method whereby water may be raised from a well through the medium of compressed air. The drop pipe in the well is supplied at the bottom with compressed air from a small air pipe, and the effect of mixture of air and water at the bottom of the drop pipe is to bring water to the surface. This is accomplished either by the water acting as pistons, trapping intermediate layers of air, the expansion of which drives the water pistons to the surface, or it may be accomplished by the mingling of air and water, forming a mixture which is sufficiently lighter than the undisturbed water in the well so that the mixture rises above the surrounding water In order for this rise to reach the surface the discharge pipe must be submerged in the water of the well an amount varying from 100–300% of the actual lift. The **pumping**

efficiency of the system is very low, but it is very suitable for handling gritty or corrosive waters. (F.T.M.)

AIR LOCK. An air lock is an air-tight compartment in which the air pressure may be regulated to any desired intensity. When men are required to work in regions where the air pressure is above (or below) that of the atmosphere, an air lock must be provided to permit passage of the workmen from the open atmosphere to the pressure region. Thus, in the case of **caissons,** where workmen must labor under a high enough pressure to equalize the **hydrostatic** pressure existing at the bottom of the caisson, or in tunnels where flooding is avoided by forcing compressed air into it at sufficiently high pressures to hold the water back, the air lock is a feature essential to the maintenance of pressure during the admission of workmen. It is also used when entering boiler rooms of steamships where, to supply forced draft to the boilers, the entire boiler room is sometimes held at a pressure slightly above that of the atmosphere.

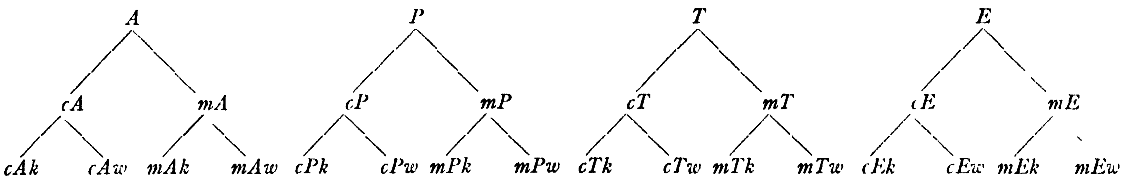
In construction work, the air lock is a chamber of sufficient size to hold the number of men that must be accommodated in it at one time. It is provided with well braced doors having sealing-type edges and tightening locks. The chamber is equipped with valves for admitting and releasing air and with safety devices to prevent excessive pressures endangering the lives of the occupants. The air lock must have two air-tight doors, one leading to the atmosphere, the other leading to the pressure region. These doors open inward so that the pressure in the air lock tends to tighten them against the frame. To enter a pressure region, a caisson for example, the workmen enter the air lock, after which the door leading to the atmosphere is tightly fastened. Compressed air is then slowly admitted until the pressure in the air lock equals that in the caisson, after which the connecting door may be opened without trouble or loss of air from the working chamber. After the workmen enter the caisson, the air lock door is tightly closed, after which the air lock may be opened from the outside without affecting conditions within the caisson.

In contrast to air locks, the decompression chamber such as is used in deep sea diving has one door. The diver, on emergence from the water, is briefly subjected to atmospheric pressure, and must be rushed to the decompression chamber and quickly subjected to pressures approximating those encountered in diving. The pressure is then slowly released, the rate of decompression being such as to prevent the malady known as "the bends." Pressures in the decompression chamber are ordinarily much higher than those for which air locks need to be built. (F.T.M.)

AIR MASSES. Very large parcels of air, ranging from about 500–5000 miles in lateral dimensions and from several thousand feet to several miles deep, which have properties (temperature, humidity, thermal structure) that vary only slightly, or vary linearly, from point to point within the parcel, are known as air masses. Air masses develop over large relatively homogeneous geographical areas where air is stagnant for a sufficient period to acquire the characteristics of that region. These regions are either continental or maritime and are known as air-mass source regions. After an air mass begins to move from its source region it acquires modifying features characteristic of the surface over which it travels. Modification continues until the air mass loses its identity in the general atmospheric circulation.

Classification of air masses begins from latitudinal consideration. There are four major zones which contribute primary classifications: 1. Arctic. 2. Polar. 3. Tropical. 4. Equatorial.

These are subdivided into Maritime (*m*) and Continental (*c*), depending upon the exact source region. Finally, each air mass must be classified as either cold (*k*) or warm (*w*). A cold air mass is one which is colder than the surface over which it is traveling and is therefore being heated from below. A warm air mass is one which is warmer than the surface over which it is traveling and is therefore being cooled from below. Capital letters are used to designate the zone location of an air-mass source: *A*, Arctic; *P*, Polar; *T*, Tropical; *E*, Equatorial. Small letters are used for appropriate subdivisions: *m*, maritime; *c*, continental; *w*, warm; *k*, cold. Small letters placed before and after the capital letter serve as descriptive symbols for the air masses.



Over North America, except for extreme northern and southern parts, only Polar and Tropical air masses occur. Areas east of the Rockies are dominated by continental Polar and maritime Tropical air masses whose contrasting features are the cause of most of the stormy weather of this section. Pacific Coast regions are almost continually under the influence of maritime Polar and maritime Tropical air masses which are cool in summer and warm in winter.

Cold air masses tend to produce cumuloform clouds, showers and thunderstorms. The visibility is relatively unobstructed by pollution or haze; it often exceeds 50 miles at ground levels and several hundred miles from aircraft in flight. Fog is infrequent. Winds are frequently gusty from mid-morning to sunset. Flying air is rough up to considerable height. Precipitation, when it occurs, is showery, often with sunshine between bursts of rain or snow.

Warm air masses favor the formation of fogs, low clouds and drizzle. Visibility is more or less universally restricted by pollution and haze which are held in a shallow surface layer by the air mass stability. Cloud forms are generally stratified types ranging from fog to altostratus. (P.E.K.)

AIR MEDICINE. The study of physiological and pathological changes (anoxia, "bends," etc.) associated with flying. (D.M.H.)

AIR PLOT. A plot showing the movements of an airplane relative to the air is known, in **navigation,** as an air plot. It is similar in every respect to the old-fashioned method for obtaining the **dead reckoning** (DR) position of a sea-borne ship, disregarding the effects of ocean currents.

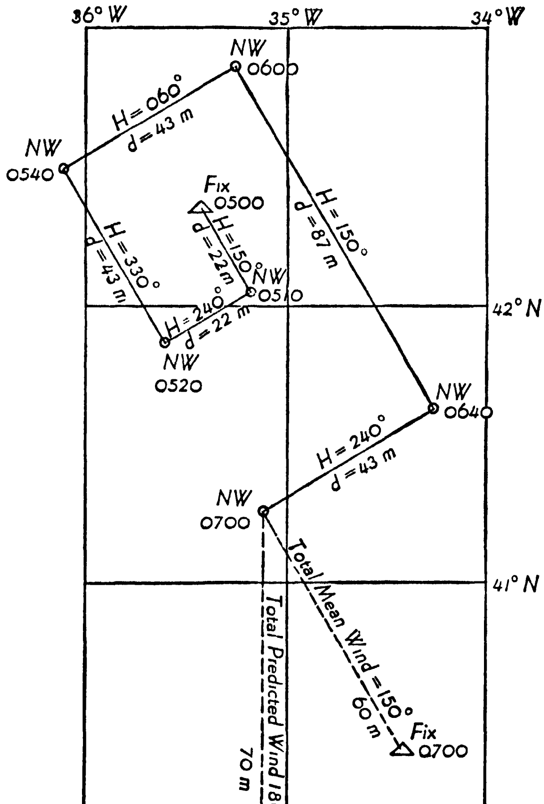
The air plot is made up of a series of distance **vectors,** added in the usual manner, the direction of each vector being a **heading** of the plane and the length is proportional to the distance moved through the air along the heading (distance = **air speed** × time on heading). The summation of the vectors gives a no wind (NW) position of the plane at any time. To obtain the DR position of the plane it is only necessary to add the total wind vector, whose direction is that of the motion of the air and whose length is the total movement (wind speed × total time since departure) of the air, to the

NW position. Such a method avoids the necessity of constructing the velocity-vector diagram to obtain course and speed along course for each heading, as is necessary in the standard method for obtaining a DR position in air navigation.

The air-plot method has been in use with British aviators for many years and is rapidly gaining favor in all air services. In cases where the plane is frequently changing headings, the air-plot method saves from 30–60% of the time involved in obtaining the DR position by standard methods. Furthermore, in the frequent cases where the predicted wind for high altitude is very inaccurate, the air plot provides a method for determining the wind.

The solution of the following problem indicates the advantages and value of the air plot. On a day when the predicted winds are uncertain, a plane is to search an area centered about a point in latitude L = 42° 22′ N and longitude Lo = 35° 25′ W. The plane, flying with true air speed TAS = 130 knots at altitude 10,000′, is over the point at 0500 and heads 150°. The altitude and air speed are maintained but the plane alters headings at the given times as follows: 0510 heading 240°, 0520 heading 330°, 0540 heading 060°, 0600 heading 150°, 0640 heading 240°. The air plot, properly labeled is shown in the figure from which the NW position at 0700 is found to be L = 41° 15′ N and Lo = 35° 07′ W.

The predicted wind at the altitude of flight is from 000° and speed 35 knots. From the 0700 NW position a vector in direction 180° and of length 70 miles is drawn. This is shown as a dotted line in the figure and represents the total movement of the plane due to the predicted wind in the two hours from 0500. This gives a dead-reckoning position in latitude 40° 05′ N and longitude 35° 07′ W.



Scale figure for air plot.

A fix is obtained at 0700 in latitude 40° 23′ N and longitude 34° 27′ W. If a vector is drawn from the NW position to the fix, it will represent the actual movement of the air in the interval from 0500 to 0700. From the diagram this is found to be in the direction 150° and 60 miles long. Since this represents 2 hours total motion of the air, we have a mean wind from 330°, speed 30 knots.

To obtain the DR position, using the standard methods of dead reckoning, would have required the plotting of at least four velocity-vector diagrams to obtain the course and ground speed on each heading. Each of these would have taken at least twice as much time as is required to plot an air vector and, after the courses and ground distances had been obtained, the geographic-motion vector diagram would have had to be plotted. Then to obtain the mean wind, the assumed air motion would have had to be subtracted from the DR position to obtain the NW position, which has to be used with the fix to obtain the actual total wind motion. (W.K.G.)

AIR POCKETS. Bump, Air.

AIR PREHEATER. There are many devices of which the purpose is to heat air for some specific usage. However, in speaking of air preheaters, what is ordinarily meant is the heater employed for raising the temperature of air used for **combustion** of a fuel. This may occur in some industrial process such as preliminary heating of the air supplied to **blast furnaces**, but the most frequent use of air preheaters today is in connection with steam **boilers**. This type of air preheater is a heating surface installed between the boiler flue gas outlet and the stack. In arrangement the heating surface is composed either of tubes with flue gas inside and the air to be heated outside, or of rectangular plates spaced about one-half inch apart, leaving alternate gas and air passages. Its use is chiefly justified on economic grounds.

Two principles are employed for heat transfer in air preheaters. The recuperative principle implies transfer of heat through a separating partition, such as the walls of a tube, by continuously recuperating the cool side with conduction of heat from the hot side. Regenerative heaters are those which alternately heat and cool the same mass, regenerating it thermally by passing hot spent gas over its surface. Regenerative heaters are frequently used with blast furnaces, and are composed of two heating chambers in which are piled checkerworks of brick having sufficient heat storage capacity for the purpose. The burned gas leaving the furnace passes through one chamber, heating up the checkerwork, while in the other chamber the heated bricks are being cooled by air passing to the combustion region. When the air-heating chamber is thermally exhausted, valves shift the flow of hot gas through that chamber, and air is drawn through the hot one. (F.T.M.)

AIR PUMPS. The earliest air pump, constructed by von Guericke (1650), differed in no essential way from the ordinary suction water pump, and was capable of producing a vacuum of the order of 1 mm. of mercury. Pumps of this type held the field for two centuries, until Geissler (1855) evolved a practical means of utilizing the Torricellian principle illustrated by the vacuum above the mercury in a barometer. This was also the plan followed in designing the Töpler pump of 1862. The Sprengel mercury pump (1865) is quite different, utilizing the air-trap action of drops of mercury falling into a narrow funnel, after the manner of the ordinary water-jet pump used for filtering, etc. These pumps were used in many pioneer researches with vacuum tubes, etc., but are far too slow and fail to give sufficiently low pressure for much modern work.

Greatly improved forms of mechanical air pump have been devised in recent years. Among these are pumps of the scraping vane type, in which a solid cylinder rotates eccentrically within a hollow cylinder, carrying

the air around by means of a blade or vane protruding radially from one and rubbing against the other; also a rotary mercury pump by Gaede, in which air is imprisoned by spiral compartments dipping into mercury, and forced out by their further rotation. Several so-called molecular pumps belong also to the mechanical class; in these the air is dragged along and expelled by the friction of a cylinder rotating rapidly inside a close-fitting casing. These rapid mechanical pumps are used for many purposes directly, and also as fore pumps or backing pumps for more effective types, in which case they serve to provide a fair vacuum into which the latter may discharge the last removable traces of gas from more highly evacuated enclosures.

The most efficient air pumps at present in use are those of the diffusion type. In most of these the pumping agent is mercury vapor issuing from a suitable boiler, the fast-moving molecules of which carry off the gas molecules diffusing into the enclosure from a side opening, somewhat as falling raindrops clear the atmosphere of dust. In Langmuir's condensation pump, the mercury vapor is prevented from entering the high-vacuum enclosure, or obstructing the diffusion, by a cold-water jacket which condenses the vapor. Such diffusion pumps, with the aid of a fore vacuum, are capable of very rapid exhaustion and are used extensively in the manufacture of x-ray tubes, radio tubes, and lamp bulbs. (L.D.W.)

AIR SPEED. Airplane Speeds.

AIR STANDARD EFFICIENCY. The actual thermal efficiency of **internal combustion** engines depends on many indeterminate factors which render the rational computation difficult, if not impossible. An efficiency may be computed, based on certain assumptions, as follows: first, that the internal combustion engine has no mechanical friction; second, that the compression and expansion in the cylinder are those of pure air, whereas actually the expanding gases are composed of nitrogen, oxygen, steam, carbon dioxide, and carbon monoxide, and the gas compressed is never pure air; third, that the compression and expansion are **adiabatic.** This would imply a heat insulation jacket around the cylinder, but the difficulties of successful lubrication have required all practical internal combustion engines to be positively cooled. The steady flow of heat from the cylinder to the cooling system destroys the possibility of an adiabatic compression or expansion. Based on these three assumptions, thermodynamic theory can be used to yield an equation of efficiency of the cycle, and such is termed the "air standard efficiency." The actual thermal efficiency will, of course, be considerably less than the air standard efficiency. Nevertheless, the air standard efficiency is useful as a measuring stick for the various designs, and it also shows the effect, on efficiency, of varying the compression ratio. The air standard efficiency of the **Otto,** or gasoline engine cycle, is given by the equation:

$$E = 1 - \frac{1}{r^{k-1}}.$$

For the **Diesel** cycle it is:

$$E = 1 - \frac{R^k - 1}{kr^{k-1}(R-1)}.$$

In these formulae, the symbols have the following meanings: r is the **ratio of compression;** R is the cut-off ratio, i.e., roughly, the percentage of the stroke through which fuel injection occurs; k varies, often being assumed 1.3 for hot air, 1.4 for cold air. (F.T.M.)

AIRFOIL. An airfoil is any body whose shape causes it to receive a useful reaction from an air stream moving relative to it. This definition is broad and could include many shapes not ordinarily considered to be airfoils. The term is usually associated with a body of the shape shown in Fig. 1. The cross-section of the airfoil is shown. The dimension perpendicular to this section is called the *span.* Many different airfoil

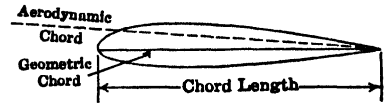


Fig. 1. Airfoil profile.

shapes have been used, proposed for use, or tested. Some of them have flat lower surfaces, while others have convex or concave surfaces. Systems have been devised for classifying and cataloging airfoils of different profiles. (See **Airfoil Classification.**)

The characteristic lifting airfoil profile has a maximum thickness of 10–15% of the chord at 20–40% of the chord aft of the leading edge. Early experiments were made with flat-plate airfoils, and later with thin curved-plate airfoils, but neither possessed as large a ratio of lift to drag as the double-surface cambered airfoil shown. Also an airfoil of finite thickness provides space for the foundation structure of a light weight **wing,** so removing the structural elements from the drag of the air stream.

The value of the airfoil shape to aviation resides in the magnitude and direction of the resultant air reaction on it when employed at attitudes below the stall (about 15° **angle of attack.**) The component of the air reaction normal to the free air stream is several times the magnitude of the parallel component. Thus lifting forces may be generated on wings by the employment of comparatively small propeller thrusts.

The generally accepted demonstration of the origin of lift on an airfoil employs a vortex circulation imposed on a rectilinear velocity field to produce the typical stream flow pattern, after which the aerodynamic forces are analyzed as originating from the impulse required to alter the momentum of the air stream, and the static pressure. Fortunately, it is possible to analyze lift on the premise of frictionless flow. Viscosity effects do not enter until drag is sought. (See **Aerodynamics.**) The dependence of lift of an airfoil of infinite span upon **circulation** Γ, free stream velocity V, and mass density ρ was proved independently by Kutta and Joukowski early in this century. Later Prandtl and others extended the "circulation theory" to cover the lift of finite wings. Joukowski's proof, considerably abbreviated, follows. The inherent tendency of an airfoil to create circulation is replaced by a **bound vortex.** A section of airfoil of unit span length is taken. The two flows are shown covering the same region in Fig. 2. Of

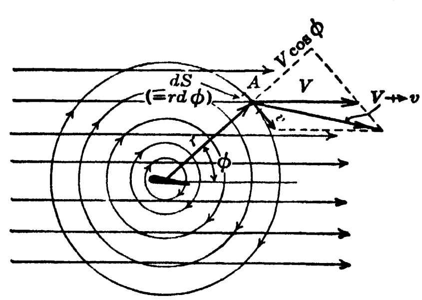

Fig. 2. Circulatory superimposed on rectilinear motion.

course this figure does not represent the actual stream flow pattern since the latter would follow the vectorial combination of these two flows. Consider the region enclosed by the imaginary cylindrical surface at radius r from the vortex center. Let r be large enough to have circulatory velocity v small compared to rectilinear velocity V and integrate for vectorial change in momentum in this cylinder and vertical component of static pressure acting against it.

The velocity of circulation, v, $= \frac{\Gamma}{2\pi r}$ and its combination with V gives the direction and magnitude of the stream line at point A. The mass of air leaving the cylindrical region at A is $\rho ds(V \cos \phi)$ and its vertical component of velocity is $v \cos \phi$. The net vertical momentum in the cylindrical mass of air, due to inflow and outflow is:

$$\oint (\rho r d\phi)(V \cos \phi)\left(\frac{\Gamma}{2\pi r} \cos \phi\right)$$

which simplifies to

$$\frac{\rho \Gamma V}{2\pi} \oint \cos^2 \phi d\phi.$$

Whence, by integration, the vertical impulse force is $\frac{\rho \Gamma V}{2}$. Since the change of momentum is downward the impulse force is upwards, i.e., it is the lift. An integration of the horizontal component of momentum yields zero net momentum

Proceeding next to evaluate the static pressure, note that Bernoulli's Theorem applied at point A is covered by the following statement. Let p be the static pressure at A, and p_0 the free stream static pressure, then

$$p + \frac{\rho}{2}(V \dashv\vdash v)^2 = p_0 + \frac{\rho}{2} V^2$$

After expanding $(V \dashv\vdash v)^2$ and dropping all v^2 terms (since A was chosen to make v small relative to V)

$$p = p_0 - \rho V v \sin \phi.$$

Since the second term on the right-hand side of this equation represents the variation from free stream pressure at point A, the lift (if any) will be the line integral of its vertical component; that is,

Vertical pressure component

$$= \oint (\rho V v \sin \phi)(\sin \phi)(r d\phi)$$

$$= \rho \frac{V\Gamma}{2\pi} \oint \sin^2 \phi d\phi$$

$$= \rho \frac{V\Gamma}{2}.$$

The horizontal integral yields zero net pressure. The total lift per unit of span is the sum of that originating from momentum and that originating from pressure. From the preceding demonstration it is seen that each contributes equally to the total lift, which becomes $\rho V \Gamma$.

Theory and experiment show that Γ is always sufficient to cause the divided flow over the upper and lower surfaces to reunite at the trailing edge without reverse flow.

If the aerodynamic chord of the wing is parallel to the free stream velocity V, the lift is zero and obviously Γ is zero. As the angle of attack is increased Γ increases nearly proportionately The strength of the circulation for an airfoil of chord c at aerodynamic angle of attack α_a is $\frac{1}{2} a V c \alpha_a$, where a is the proportionating factor. Since Lift, L, $= \rho V \Gamma b$ (b = span), it also equals

$$a\alpha_a \frac{\rho V^2}{2}(bc).$$

Call $a\alpha_a$ the coefficient of lift, bc the area S, and $\frac{\rho V^2}{2}$ the dynamic pressure q, then the lift equation becomes.

$$L = C_L q S.$$

The variation of C_L with geometric angle of attack is seen in Fig. 3. The slope of the straight portion is a

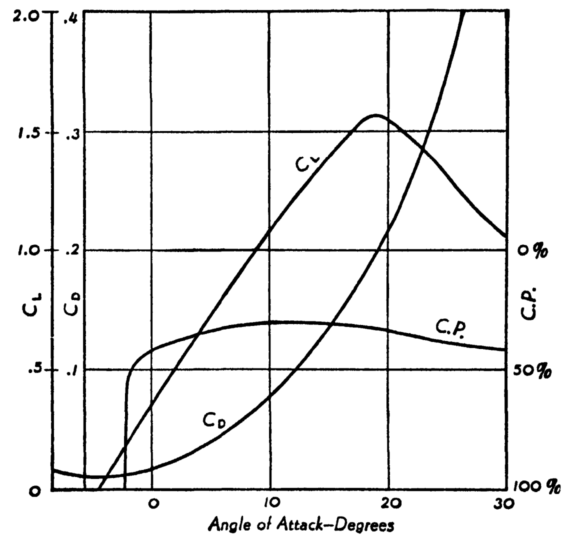

Fig. 3. Common aerodynamic characteristics of a Clark Y airfoil.

per radian. Theory indicates a value of 2π for a and tests agree well with the theory. The lift coefficient increases uniformly with angle of attack until the **stall or burble** point is reached, where it breaks and decreases rapidly with further increase of angle of attack because the high attack angle creates a bluff body and the **stagnation point** advances forward on the airfoil.

The full aerodynamic reaction upon an airfoil is a force of which the lift is the component normal to the free stream velocity. The other component is measured in the direction of the air velocity and is called drag. Drag coefficient has a characteristic parabolic variation, as Fig. 3 shows. The drag equation is analagous to that for the lift:

$$D = C_D q S.$$

If the resultant of all air reactions on an airfoil is consolidated into a single imaginary force, it must act at the **center of pressure** of the airfoil. The figure shows that the location of this center of pressure of an airfoil varies with its attitude.

If the airfoil has a finite span (i.e., definite tips), the **bound vortex**, assumed for the purpose of accounting for lift, is found to extend from the tips downstream as a free vortex. The effect of these tip vortices is to modify the air reaction since a **downwash**, w, is produced at the lifting line (see figure). The effect of

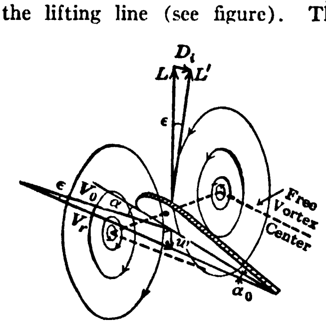

Fig. 4. Perspective of a section of airfoil subject to downwash from the free vortices at the tips.

downwash is to change the lift direction from L to L' since the relative wind, V_r, is now inclined. The angle ϵ is always small so L' may be considered of the same magnitude as L. However, L still remains the significant lift since the free stream velocity is V_0. Consequently, a drag D_i is introduced, although the original assumption of zero air viscosity remains in order.

This *induced drag* is a feature of the motion of ideal, frictionless air over an airfoil of finite span. The longer the span, the less the average effect of downwash (since in vortex motion $v \sim r^{-1}$) and the less the induced drag, but it will not disappear unless the span extends to infinity. By application of hydrodynamic theory beyond the scope of this article, aerodynamicists have shown that:

1. Minimum induced drag for a given lift and span will be had if downwash is of constant magnitude over the span.
2. Constant downwash will result from a bound vortex circulation strength of elliptical spanwise character (see **Vortex Sheet**).
3. Elliptical spanwise Γ occurs on an untwisted airfoil of elliptical planform.
4. With elliptical Γ a simple relation connects induced drag and aspect ratio.

$$D_i = L^2/\pi \mathit{R}.$$

This relation holds for the coefficient, too.

$$C_{D_i} = C_L{}^2/\pi \mathit{R}.$$

As

$$\frac{D_i}{L} = \frac{C_{D_i}}{C_L} = \frac{W}{V_0} \text{ (nearly)},$$

$$\alpha = \alpha_0 + C_L/\pi \mathit{R}.$$

It appears that a finite wing possesses an induced drag of C_{D_i} not possessed by an infinite wing in ideal flow, also an induced angle of attack, requiring the angle of attack α of the finite span to be more than α_0 of an infinite span for the same lift per unit of span. The differences of induced drags of two airfoils of the same profile at the same lift coefficient but with different planforms follow naturally from the above:

$$C_{D_i1} - C_{D_i2} = \frac{C_L{}^2}{\pi}\left(\frac{1}{\mathit{R}_1} - \frac{1}{\mathit{R}_2}\right).$$

It is commonly assumed that the difference between the total drag coefficients of two airfoils of the same profile but different aspect ratios is the difference in induced drag. Likewise the difference in necessary angle of attack to the free stream velocity for the same C_L is.

$$\alpha_1 - \alpha_2 = \frac{C_L}{\pi}\left(\frac{1}{\mathit{R}_1} - \frac{1}{\mathit{R}_2}\right).$$

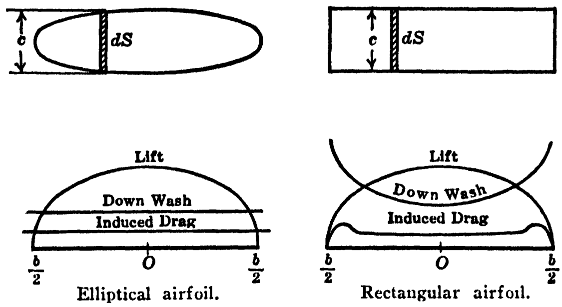
While these induced effects are premised on elliptical planform for the airfoil, they hold very well for rectilinear airfoils with elliptical tips and those with moderate taper ratio.

The lateral or spanwise distribution of lift on an airfoil depends on the planform and the distribution of downwash. Two cases are illustrated—an elliptical airfoil and a rectangular one.

1. The effect of downwash is to reduce the effective angle of attack and hence the lift coefficient. The lift of any lateral element dS is proportional to the product of C_L and c; hence the lift distribution of an elliptical wing is elliptical, while its induced drag, mirroring the downwash, is constant.
2. The downwash strength increases near the tips of a rectangular wing. The lift coefficient accordingly declines and lift falls off at the tip even though chord is maintained. Induced drag is strong at the tips.

This discussion of the origin and nature of aerodynamic reactions on the airfoil is concluded with a brief résumé of qualities of an airfoil which are sought for when it is employed in aviation.

1. High maximum C_L, in order to give low landing speed for a given size wing.
2. Low minimum C_D, so that the high speed, which occurs at small angles of attack, may be the greatest possible.
3. High ratio of C_L to C_D, so that an efficient, economical airplane will result.



Elliptical airfoil. Rectangular airfoil.

Fig. 5. Spanwise variations.

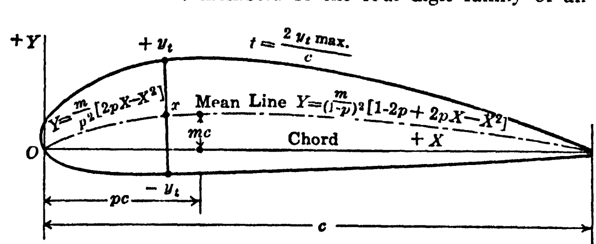
4. Minimum variation of the center of pressure, so that it will not be difficult to construct a stable airplane.
5. A shape well suited to the construction of a strong, but light-weight wing, at minimum cost. (F.T.M.)

AIRFOIL CLASSIFICATION. The shape of an airfoil depends on several controlling dimensions, and the number of variations possible is extremely great. The profiles which have been proposed, experimentally tested, or built into airplane wings, are sufficiently numerous to have caused some attempts at systematic classification. Elementary classifications such as (1) thin, (2) thick, (3) low drag, (4) high lift, (5) single camber, (6) double camber, (7) reflexed, etc., lack sufficient detail to be of much use.

During the evolution of aviation various unconnected classifications grew out of the identification of series of airfoil profiles by those who developed them or by the laboratories that tested and reported their characteristics. Thus there were the Munk series M1, M2, M3, the Göettingen Laboratory series, an RAF series, etc.

From studies made by the **NACA** it was found that when a number of the better and more used airfoil profiles were "straightened," that is, their mean camber lines were made straight lines, and were proportionally reduced so that all had the same thickness, the profiles were almost identical. From this discovery was evolved the idea that an airfoil could be described by a standard thickness function and a camber line function. Two numerical classification systems have been devised, viz, a four-digit and five-digit system.

The **NACA** four-digit system of airfoil classification describes (1) the maximum camber of the mean line, (2) its position on the chord, (3) and (4) the maximum thickness. Thus the 4312 airfoil has a maximum mean camber of 4% of the chord at a position .3 of the chord from the leading edge and a maximum thickness, t, of 12% of the chord. The mean line is composed of two parabolas joined at the maximum camber point, as shown in the figure, with variations in p and m to produce different members of the four-digit family of air-



foils. The thickness function adopted for this classification is:

$$\pm y_t = [t/0.2][.2969x^{1/2} - .1260x - .3516x^2 + .2843x^3 - .1015x^4]$$

The radius of the leading edge is $1.1t^2$.

The five-digit system similarly employs a combination of numbers to describe camber line and thickness. The camber line in this series is composed of a cubic which

becomes tangent to a straight line comprising the rear portion of the mean camber line, or, alternately, to a reflexed cubic. (F.T.M.)

AIRFOIL EFFICIENCY FACTOR. This is a correction factor used to reconcile the theoretical aerodynamics of induction (see **Airfoil**) with experimental data. Induction theory yields 2π for the value of $dC_L/d\alpha$, the rate of change of lift coefficient with angle of attack. Actually, $dC_L/d\alpha = 2\pi e$, where e is "airfoil efficiency factor," usually 90% or more. (F.T.M.)

AIRPLANE, FIXED WING. An airplane is an aircraft of the heavier-than-air type, deriving its sustention from aerodynamic reaction on the sustaining surfaces, and propelled by a force, usually the thrust of an air propeller, which is driven from some adequate source of power. Alternately, reaction propulsion of jets may be employed. The practical airplane of the present time consists of the following components:

1. Wing (or wing cellule, in the case of multi-planes), to provide the required lift.
2. Power unit, consisting of one or more prime movers, usually internal combustion types, attached to an air propeller by means of which a thrust sufficient to overcome the drag of the airplane is produced.
3. Fuselage, or body, which is required to house the crew, passengers, and cargo, and serves as the foundation structure of the airplane. The other components are usually, though not always, fastened directly to the fuselage.
4. Undercarriage for supporting the airplane when on the ground or on the water.
5. Controls for giving maneuverability, and allowing the pilot full control of the motion and performance of the airplane.
6. Stabilizing surfaces for imparting automatic aerodynamic stability to the airplane.

The foregoing components are assembled in a great many different ways in the aircraft of the present time, but a common arrangement has a single **wing**, or monoplane, attached directly to the **fuselage** and braced with **struts**, or more commonly attached without external supports, in which case the wing is designated a cantilever monoplane as will be indicated more fully later on. The power plant (see **Aeronautical Engines**) is mounted in the nose of the fuselage with an air **propeller** bolted directly on the engine **crankshaft.** The fuselage has its maximum section at the point which houses passengers and pilot, and tapers from there to a tail located some distance behind the wing. The tail consists of a horizontal surface and a vertical surface, each divided into fixed and movable portions. The movable tail surface, together with the **ailerons** in the **wings**, are actuated by controls operated from the cabin. When on the ground, this plane rests on two main wheels carried by a short undercarriage of struts and bracing, and upon a tail wheel at the rear. The location of the center of gravity is such that the main wheels carry most of the weight of the plane. In modern aircraft a popular variant of the landing gear is one in which a swiveling wheel is placed at the nose of the fuselage, and the two main wheels are placed just aft of the center of gravity. Such a landing gear, termed a tricycle landing gear, facilitates cross-wind landings.

If we were to imagine an aircraft of this type taking to the air, the operation would be somewhat as follows: The plane is at the end of a level straight runway about 2000′ long, with the engine idling, but warmed up and ready to deliver full power. The plane is heading into the ground wind, if there is one. To **take off**, the pilot opens the throttle wide and operates the movable portion of the horizontal tail surfaces to lift the tail from the ground under the influence of the air blast from the propeller, and hold the longitudinal axis of the airplane horizontal. Meanwhile, under the influence of the propeller thrust, the plane is traveling on its landing gear, with increasing speed, down the runway, being guided in a straight line with the use of the rudder, which is the movable portion of the vertical tail surfaces. As the speed increases, aerodynamic reaction of lift on the wing surface builds up steadily, and after a run of from 600–1500′, depending on the circumstances, the lift is nearly equal to the weight of the airplane, and could readily be made to exceed it by increasing the angle of attack on the wings. At this point the pilot may elect to continue the same take-off attitude until the lift equals the weight of the plane, and the plane leaves the ground, or he may elect to operate the movable horizontal tail surfaces, called the elevator, and thus increase the **angle of attack**, and the lift, so that the airplane will leave the ground at some definite point.

Once in the air, the plane has three degrees of freedom, and the maneuvering of the plane involves simultaneous coordination of controls for three basic airplane motions, the pitch, the roll, and the yaw. Referring to Fig. 1, the three mutually perpendicular axes about

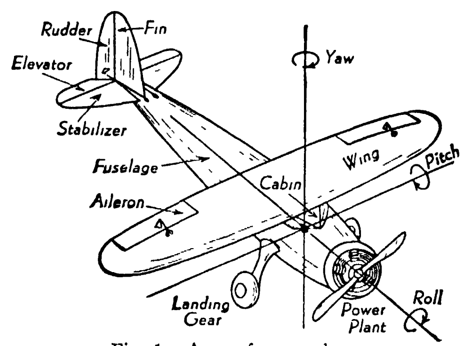


Fig. 1. Axes of an airplane.

which motion of an airplane takes place are the longitudinal axis of the airplane, the horizontal axis, which is parallel to the wing, and the vertical axis. These intersect at a common point, which is the **center of gravity** of the airplane. The rotation to the right or left around the vertical axis is called a yaw, and is obtained by the use of the rudder. Motion about the lateral axis is called pitch, and is controlled by the elevator. Rotation around the longitudinal axis is called roll, and is controlled by the ailerons. Parts of the vertical and horizontal tail surfaces are fixed for the purpose of giving longitudinal and directional stability to the airplane, whereas lateral stability is obtained by setting the wings at a slight dihedral angle.

Stability in an airplane is that ability which the airplane possesses of itself, and without aid from the pilot, of returning to a normal horizontal flight position when once displaced from that position by gusts. An airfoil, alone, is unstable. For instance, a slight unintentional increase of the angle of attack creates aerodynamic forces which tend to increase that angle rather than to decrease it. Nevertheless, stable airplanes can be built incorporating unstable airfoils through the medium of a fixed surface—a tail—placed at some distance behind the wing, or through a large amount of sweepback of the wings, a method employed in the tailless airplane. If, in the conventional arrangement of the components of an airplane, the center of gravity of the entire airplane is placed about one-third of the wing chord aft of its leading edge, and the tail surfaces between two and three chord lengths to the rear of the wings, the airplane will likely be stable, provided, of course, that the proper relation obtains between wing area and tail area.

The operation of the control surfaces, which involves their rotation around a hinge point through an angle of 10 to 20°, is accomplished from the pilot's seat by connecting horns on the control surfaces to controls at the seat by cables, torque tubes, or push-pull tubes. The rudder is operated by foot pedals, the ailerons and ele-

vator by a control column having two degrees of freedom, or a column with one degree of freedom upon which is mounted a rotating wheel. In the wheel type of control, turning the wheel operates the ailerons, while moving the control column operates the elevator. In large airplanes, the force required of the pilot becomes very great unless the control surfaces are balanced by placing their hinges aft of the leading edge or by employing power boost to supplement manual effort.

Most airplanes can be classed structurally as trussed types or stressed skin types. The trussed structure used in the United States utilizes a triangularly framed fuselage of alloy steel or duralumin tubing, either welded or riveted at the joints. This has been a very popular modern type everywhere.

Stressed skin construction has no triangular framework, but rather relies upon the tube-like strength of the outer skin, which is oval or circular in cross-section, and which is made of thin sheet metal, or plywood. Thin sheets of the size required to cover a fuselage would be very weak were they not reinforced at intervals with bulkheads, or diaphragms, and longitudinal stringers. This construction has the advantage of a high strength-weight ratio, but is better adapted to large transport airplanes than to small private-owner types. The attachment of fittings to the stressed skin structure is much more of a problem than in the case of the trussed frame fuselage.

The wing is the most important element of the airplane since it produces the lift which overcomes the weight of airplane and contents and makes flight possible. The wing is a structure over which may be placed a surface of fabric, sheet metal, or plywood. The structure will be so shaped that the covering assumes an **airfoil** shape. One (monoplane) or two (biplane) wings will be rigidly fastened to the fuselage so that the air reaction received by the wing surface, and passed on to the wing structure, can act on the fuselage. The wing structure is sometimes purely cantilever, sometimes externally braced.

All parts of the airplane exposed to the air stream are subject to aerodynamic drag, the sum total of which must be overcome by the propeller thrust in order to maintain speed. The drag of all parts except the wings is parasitic drag, that is, it is the drag of objects which do not create any useful lift. The less this parasitic drag, the less power will be required to propel the airplane at a given speed. By streamlining the struts, concealing fittings, cowling the engine, filetting wing roots and other angular intersections, retracting landing gear, etc., airplane designers have endeavored to reduce parasitic resistance and increase performance. The modern airplane of the low-wing cantilever type, with retractable landing gear, is an example of low parasitic resistance. Speeds of over 400 m.p.h. are thus obtained.

Location of the power plant in an airplane is subject to great variation. The single-engined airplane of the past was almost invariably a tractor type, with the engine mounted in the nose of the fuselage. The present and future may see an increasing use of pusher airplanes, in which the engine is to the rear of the cabin, as this yields a superior arrangement from the standpoint of visibility and access to the cabin. It is also better from the standpoint of noise and odors. For reasons of clearance, the engine of the flying boat, or amphibian airplane, is mounted atop the wing, where the propeller will be in less danger from damage by spray or wave. The multi-motored installations, with two engines, usually have the engines mounted in the leading edge of the wing, one on each side of the fuselage. The third engine in trimotored design is placed in the nose of the fuselage. In four-motor designs, the engines have been spaced in the leading edge of the wing. The National Advisory Committee for Aeronautics found by research that the placing of the engine just ahead of the leading edge of a wing, coupled with careful streamlining of the engine frame into the wing, resulted in the best aerodynamic results—that is, the propulsive efficiency was high, and the aerodynamic characteristics of the wing were but little affected.

The structure for support of the airplane while at rest on the surface, or while taking off or landing, is naturally different in the case of land and water designs. Undercarriage for land planes consists of three or more wheels supporting the weight of the plane, and holding it sufficiently high off the ground, so that there is no danger of contact of the rotating propeller with the ground. As it is possible for the airplane to contact the ground upon landing in a very severe manner, the landing gear must be very rigid and strong, and should be provided with some means, such as pneumatic or hydraulic shock absorbers, to absorb some of the energy of the impact. Whereas two wheels and tail skid, or wheel, have been common practice in the past, a great deal of attention is being given now to three-wheel landing gear, in which the third wheel is ahead of the center of gravity, and the other two behind. The advantage of this arrangement is that brakes may be applied heavily to the two main wheels without any danger of turning the airplane over on its back, as was the case with the older design. It has already been mentioned that advantages of performance are to be secured by retracting landing gear into the fuselage after the airplane has left the ground. This is done on nearly all transport type airplanes, and on a great many sportsman planes as well where high performance at moderate power is desired. Many interesting mechanically, hydraulically, or electrically operated retracting landing gears have been devised and successfully applied. Every effort is made to have these retractable gear absolutely reliable, although it has been proven, in several instances, that an airplane may land on the belly of the fuselage with wheels retracted without serious injury to its occupants, and sometimes with only minor damage to the airplane.

Airplanes designed to land on the water are classed as seaplanes, or flying boats. The seaplane resembles a land plane with the undercarriage removed, and replaced by another of similar design, but with floats in place of wheels. The flying boat is structurally quite different The fuselage, for instance, becomes a hull, and is shaped considerably like the hull of a speed boat. The tail is not carried by the hull, but by special tail-carrying structural members extending backward from the wing The wing is usually above the hull, for water clearance, and the engine either in the leading edge of the wing, or mounted on a stand above it. Amphibians are essentially flying boats, with retractable landing gear to enable their landing on smooth fields when necessary. (F.T.M.)

AIRPLANE, JET PROPELLED. An airplane "flies" by virtue of a lift produced by wings. These same wings, together with the remainder of the airplane, incur a **drag**. The latter includes the price paid for lift. It is the function of the propulsion system to produce a forward thrust at least equal to the drag and, sometimes, for accelerating or climbing maneuvers, to exceed it. The thrust can be derived (1) from an airscrew, (2) from the reaction to a fluid jet, (3) from a component of the aircraft's own weight, as in soaring (**Sailplane**), (4) from a tow as in the case of a **"glider."** Number one is the conventional and usual method, but number two is the present subject. A **jet engine** will produce a reaction force on the engine body, which, being rigidly fastened to wing or fuselage, transmits that force as a propelling thrust. The principles of thrust production are covered under **Jet Propulsion,** so the present section will be confined to the airplane itself.

Most jet planes are powered by combustion **gas turbine** or turbo-jets and are not like rockets. Rocket-powered designs have been built for special military purposes, but cannot be considered to have shown much promise outside a few military applications. Also rock

ets have helped heavily loaded planes into the air and shortened the take-off run of others. (See **Rockets** and **Rocket Assist.**)

But the turbo-jet powers most of the jet airplanes. The airplane itself does not need to be radically altered to use jet propulsion. Stability and control remain about the same, and superficially the jet plane may appear about like any others. The differences are:

1. The jet plane fuel may be kerosene or some other fuel not possessing the fire hazard of gasoline.
2. Since propeller clearance is not a specification, ground clearance—which sometimes dictates the length of undercarriage—is reduced. This is accompanied by a whole group of advantages, structural and aerodynamic. Also, in bi-motored designs, engines can be set close to the fuselage, thus reducing the effect of unbalanced thrust when one engine is out of commission.
3. The front projected area of a large jet engine is smaller than that of the radial engine of equivalent horsepower.
4. Reciprocating engine type of vibration is eliminated.
5. High-powered jet engines are lighter than reciprocating types.
6. The jet plane performance holds up better at extreme altitudes.
7. At high speeds, especially, the jet plane is the more efficient.

No new flight problems are presented to a pilot by the jet engine; in fact controls are simplified. Since the jet plane has a propulsion system that can function near or above the speed of sound, airplane design is not limited to the subsonic range as it probably is with propeller type engines. The jet airplane of the future may have sharp or pointed forward shapes. Wings may no longer have the usual blunt leading edges, fuselages may be tapered to a sharp point, cabins may be wholly submerged in the smooth streamlined fuselage.

At low speeds and altitudes the jet plane compares poorly with the conventional airplane. In take-off, rate of climb, and efficiency in the use of fuel, the reciprocating engine and screw propeller prove to be superior. But let the flight be in the stratosphere at the high speeds of 500 or 600 m p h, and the jet is supreme. (F.T.M.)

AIRPLANE, ROTATING WING. Helicopter; Autogyro.

AIRPLANE EFFICIENCY FACTOR. This term, originally introduced by W. B. Oswald, is intended to reconcile the actual drag variation of a complete airplane with the ideal equation for drag coefficient, viz.,

$$C_D = C_{D_p} + C_{D_i}$$

in which C_D = Airplane drag coefficient
C_{D_p} = Wing profile drag and airplane parasite drag coefficient
C_{D_i} = Induced drag coefficient.

It has been found that the actual C_D vs. C_L (coefficient of wing lift) curve of an airplane is closely fitted by the ideal equation if an arbitrary "airplane efficiency factor" e is introduced, thus.

$$C_D = C_{D_p} + C_{D_i}/e \qquad \text{(F.T.M.)}$$

AIRPLANE SPEEDS. An airplane has three degrees of freedom, and in flight is sustained by a fluid medium which itself may be in motion relative to the ground. This combination provides possibilities for a variety of both critical and non-critical velocities. The speeds of the more important of these are described below.

Design Gliding Speed. Arbitrarily set value of maximum indicated airspeed used in determining pertinent structural loading conditions in commercial airplane design. Pilots should not exceed this speed in glides or dives. In the United States this speed is restricted to 150% of the maximum level speed, or less (depending on loading conditions).

Ground Speed. The horizontal component of the velocity of an aircraft, relative to the ground. Determines distance travelled.

Indicated Airspeed. True airspeed multiplied by

$$\sqrt{\frac{\text{atmospheric density}}{\text{std. sea level density}}}$$

Landing Speed. The minimum speed of an airplane at the instant of contact with the landing area in a normal landing. This would be stalling speed for some aircraft, while for others (3-wheeled undercarriage) it might be somewhat higher.

Maximum Level Speed. The indicated airspeed obtained in level flight using rated engine horsepower. Taken at the altitude where it reaches maximum value.

Maximum Vertical Speed. Terminal velocity in vertical flight path. A fictitious airspeed resulting from diving an unlimited distance in air of uniform density (assumed sea level conditions) with normal gross weight and zero propeller thrust.

Stalling Speed. The speed of an airplane in steady flight at its maximum coefficient of lift.

True Airspeed. The speed of an aircraft relative to the air. Determines aerodynamic reactions. (F.T.M.)

AIRSCREW. A term having the same meaning as air **propeller.** The rotating airfoil used to produce a forward propulsive thrust for aircraft is called *propeller* in the United States, but elsewhere airscrew will often be the accepted term. (F.T.M.)

AIRSHIP. The airship is that form of aircraft which derives its lifting power from aerostatic forces rather than the **aerodynamic** forces such as support the **airplane.** In other words, the lift of an airship is one of **buoyancy,** and this is derived from the difference between the density of the atmosphere and that of the lifting gas contained by the airship. The gases most commonly used are **hydrogen** and **helium**—the two lightest known gases. Hydrogen is cheaper than helium, but helium has the very distinct advantage of being non-inflammable. The explosion hazard is reduced to a minimum in a helium-filled airship. The size of an airship is determined by the volume of lifting gas required to lift the weight of the ship and the load. The lifting power of helium is approximately .07 lb. per cu. ft. at 32° F., standard atmospheric pressure, and that of hydrogen is 6% more. The airship is equipped with a propulsive device and controls, so that its attitude, speed, altitude, and course are under the control of the pilot, whereas in the free balloon, altitude only is controllable, and velocity depends entirely upon the wind.

The requirements of navigability and **aerodynamic efficiency** have caused an effective aerodynamic shape to be given the airship. This shape is usually circular in cross-section, with a rounded nose and a tapering tail. The ratio of length to diameter varies between 5 and 8. Propulsion is obtained from air **propellers** driven by internal combustion engines, which are either mounted in **nacelles** attached to the hull, or are within the hull, and drive the propellors by means of shaft and gearing extending through the skin of the hull. The latter location is considered safe only in helium-filled airships.

There are three principal classifications of airships, i.e., the non-rigid, semi-rigid, and rigid. The shape of the non-rigid airship is maintained by the pressure of the lifting gas. However, the gas expands and contracts with temperature, and in the contracted state the airship would be limp (the popular name blimp is derived from a war time designation of this as the B-limp type), were it not for an air-filled ballonet which is built inside the main covering. As the lifting gas expands it forces air out of the ballonet, and when the lifting

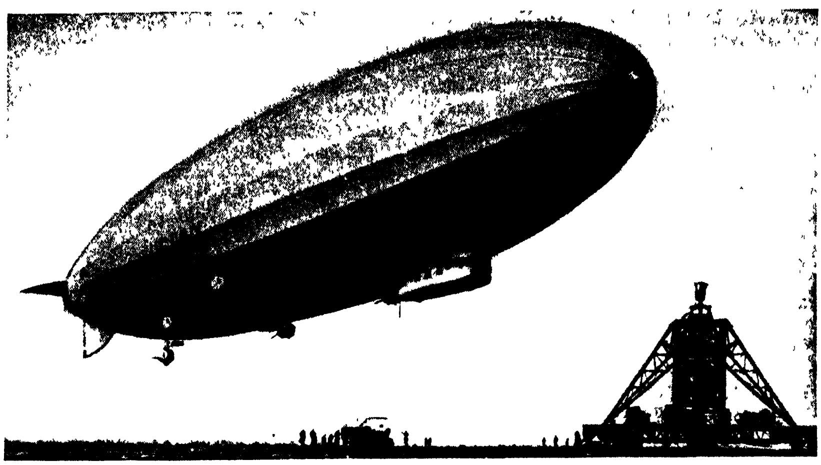

Fig. 1. Dirigible airship.

Fig. 2. Semi-rigid airship.

gas contracts, air scoops fill the ballonet by virtue of the velocity of the airship. The variable volume ballonet can also be used by the pilot to regulate the altitude of the airship by using it to compress or expand the lifting gas, so changing its density and lifting power. The ballonet is emptied for ascent, and refilled for descent. The cabin and engine installations are carried in the car or in nacelles, which are suspended below the envelope.

The rigid, or dirigible airship, has a complete metal framework, and its shape is, accordingly, independent of the degree of inflation of the lifting gas cells which are contained within. Fixed equipment, like power plants and living quarters, is rigidly attached to the structural frame. The semi-rigid airship resembles the non-rigid in that its shape is maintained by gas pressure, but there is a structural keel extending longitudinally from the nose to the tail, with additional structural reinforcement at the nose and at the attachment of the control surfaces. In size, the blimps are the smallest, and the dirigibles the largest, airships.

The framework of the modern dirigible is made of girders running longitudinally connected by parallel circumferential rings. The circumferential rings must be absolutely rigid, and if the construction is not such that their shape is self-sustaining, they must be braced diametrically. One to three of the longitudinal members at the bottom of the hull are made especially heavy and rigid to form a keel. The keel serves to strengthen and integrate the ship fore and aft, provide main walkways for access to the interior of the ship, and support heavy equipment, such as cabins, engines, and control surfaces. (F.T.M.)

AIR-SPEED METER. An instrument used for measuring the speed of an airplane relative to the air is known as an air-speed meter.

One early type of air-speed meter employed a small propeller which was located out on the wing of the plane, well outside of the slip stream of the plane's propeller. The rpm of the small propeller is proportional to the speed of the plane through the air.

The propeller type of air-speed meter has been superseded by an instrument which employs the principle of the **Pitot tube.** The instrument is placed well out on the wing, beyond the influences of the slip stream of the propeller, and the leads from a **piezometer** tube and the Pitot tube are brought into different chambers separated by a pressure-sensitive element similar to that used in an aneroid **barometer.** The changes in thickness of this element are transmitted and amplified by a system of levers and gears to a dial, which will read directly in **knots** on naval planes, or statute m p h on army or commercial planes. When the instrument is properly adjusted for standard atmospheric conditions of pressure and temperature, the reading of this dial is what is known as the indicated air speed.

To obtain the actual speed of the plane relative to the air, the indicated air speed must be converted to calibrated air speed by means of a calibration curve determined for the particular instrument being used. The calibrated air speed is then converted to true air speed by means of a formula involving the calibrated air speed, the temperature of the air, and the altitude at which the plane is flying. This final conversion from calibrated air speed to true air speed may be made rapidly on any one of a number of standard **navigational computers.** (W.K.G.)

AIRWORTHINESS. The quality of an aircraft denoting its fitness and safety for operation in the air under normal flying conditions. (F.T.M.)

AIRY'S EXPERIMENT. **Aberration of Light.**

AITKEN'S METHOD OF INTERPOLATION. Given the arguments a, b, c, d and the corresponding values of the function u_a, u_b, u_c, and u_d, we desire the value of u_x, $a < x < d$. We use the simple method provided by A. C. Aitken. This method works for unequal intervals for the argument as well as equal intervals, for inverse interpolation as well as for direct interpolation, and it provides a way of determining the number of significant figures in u_x.

A table is constructed as follows to find u_x:

				Parts
u_a				$a - x$
u_b	$u_x(a,b)$			$b - x$
u_c	$u_x(a,c)$	$u_x(a,b,c)$		$c - x$
u_d	$u_x(a,d)$	$u_x(a,b,d)$	$u_x(a,b,c,d)$	$d - x$

We calculate the entries in the table

$$u_x(a,b) = \frac{\begin{vmatrix} u_a & a - x \\ u_b & b - x \end{vmatrix}}{b - a},$$

$$u_x(a,c) = \frac{\begin{vmatrix} u_a & a - x \\ u_b & c - x \end{vmatrix}}{c - a},$$

$$u_x(a,d) = \frac{\begin{vmatrix} u_a & a - x \\ u_d & d - x \end{vmatrix}}{d - a},$$

$$u_x(a,b,c) = \frac{\begin{vmatrix} u_x(a,b) & b - x \\ u_x(a,c) & c - x \end{vmatrix}}{c - b},$$

$$u_x(a,b,d) = \frac{\begin{vmatrix} u_x(a,b) & b - x \\ u_x(a,d) & d - x \end{vmatrix}}{d - b},$$

$$u_x(a,b,c,d) = \frac{\begin{vmatrix} u_x(a,b,c) & c - x \\ u_x(a,b,d) & d - x \end{vmatrix}}{d - c},$$

$$= u_x.$$

We may stop the calculations whenever the particular column $u_x(a, b, \cdots)$ shows an agreement to the number of significant figures desired. For example if $u_x(a, b, c)$ and $u_x(a, b, d)$ agree to 4 significant figures. then u_x would be that result to 4 significant figures. Aitken's method corresponds to polynomial interpolation, and in the illustration cited with 4 points a polynomial of the third degree is being used The points (a, u_a), (b, u_b), (c, u_c) and (d, u_d) may be arranged in any order without affecting the value of u_x. (L A.A.)

ALABAMINE. **Chemical Composition, I. Elements.**

ALABANDITE. **Manganese** sulfide, MnS. Associated with pyrite, sphalerite and galena as vein deposits. (R.M.F.)

ALABASTER. A fine-grained variety of the mineral **gypsum,** formerly much used for vases and statuary. It is usually white in color or may be of other light, pleasing tints.

The word alabaster is derived from the Greek name for this substance. (E.S.C.S.)

ALAGDAGA. **Jerboa.**

ALALITE. **Diopside.**

ALANINE. **Aminoacids.**

ALARY MUSCLES. Muscles which attach the heart of **insects** to the body wall and diaphragm. (A.W.L.)

ALBATROSS. Aves, Procellariiformes. A large marine bird (**Aves**) with unusual powers of flight, as is known from its habit of following ships for many hours without alighting. There are several species, belonging to *Diomedea* and allied genera. (A.W.L.)

ALBEDO. The term albedo is used astronomically to indicate the reflecting power of an object. Technically defined, albedo is the ratio of the radiation reflected from an object to the total amount incident upon it For example, the albedo of the moon is 0.073 which means that the moon reflects that fraction of the sunlight which is incident upon it.

The value of the albedo of a planet is a measure of the quantity of **atmosphere** which surrounds the object. The higher the albedo the thicker the atmospheric layer. In the case of objects without atmosphere, as in the case of the moon, the albedo, combined with the color of the reflected light, may be used to make estimates of the character of the material making up the surface of the object. (W.K.G.)

ALBERT EFFECT. A reaction of light-sensitive photographic materials discovered by E. Albert in 1899. Albert found that if a wet collodion plate is considerably overexposed and the latent image destroyed with nitric acid, a positive image is produced upon exposure to white light and subsequent development. Albert's observations with wet collodion have been shown to hold also for gelatin emulsions by Luppo-Cramer, J Precht and others. The effect is produced by chromic acid, ammonium persulfate and other substances which destroy the latent image as well as by nitric acid (C.B.N)

ALBERTITE. An oxygenated **hydrocarbon** which differs from **asphaltum** slightly in that it is not completely soluble in **turpentine,** nor can it be perfectly fused. Its hardness varies from 1 to 2; specific gravity 1.097; luster pitchy; color black.

It occurs as fissure filling in the **Carboniferous** rocks of Nova Scotia. (E.S.C.S)

ALBINISM. Absence of pigmentation. The condition has been noted in occasional individuals of many species which are normally pigmented, including man. In some cases the term is applied to a partial lack of pigment, as in the white form of certain normally yellow butterflies; in this form the black markings characteristic of the species are fully developed. In contrast, the total lack of pigment in albino birds and mammals is shown by the pink eyes. In these organs pigment is functionally important but the albino fails to develop it, hence the color of the blood is seen through the tissues

Albinism in man is known to be inherited as a recessive (see **Heredity**) to normal pigmentation The term is also applied to normally green plants which fail to develop chlorophyll. As in man, albinism is inherited as a simple recessive. Albino plants die as soon as food is exhausted from the seed. Partial albinism in plants is known as variegation. (A.W L., P A W)

ALBINO. An individual without the normal pigmentation of its kind. (See **Albinism.**) (A.W.L.)

ALBITE. **Feldspar.**

ALBUMIN. An albumin is a member of a class of proteins (see **Aminoacids, Polypeptides, and Proteins**) which is widely distributed in animal and vegetable tissues. Albumins are soluble in water and in dilute salt solutions, and are coagulable by heat.

The repeated appearance of albumins in the urine (albuminuria) may indicate a diseased condition of the kidneys. (See **Nephritis.**) (D.M.H.)

ALBUMINOIDS. **Aminoacids, Polypeptides, Proteins.**

ALCOHOL. This is the name of a type of chemical compounds which are discussed under the heading, **Alcohols.** Ethyl alcohol, the member of the series in most common use and of most common occurrence, is often referred to by the group named, that is, simply as alcohol. It is discussed in this book under the heading **Ethyl Alcohol.** (R.K.S.)

ALCOHOLIC INSANITY. Ethyl Alcohol.

ALCOHOLISM. Ethyl Alcohol.

ALCOHOLS AND ETHERS. Alcohols (containing hydroxyl groups, —OH, attached to non-benzenoid carbon) are characterized by a wide variety of chemical reactions and uses, well illustrated by reference to particular alcohols, namely, methyl alcohol, ethyl alcohol, glycol, glycerol. There are three types of alcohols, illustrated as follows: (1) primary, $CH_3—CH_2OH$, ethyl alcohol, methyl carbinol, (2) secondary, $(CH_3)_2{=}CHOH$, isopropyl alcohol, dimethyl carbinol, (3) tertiary, $(CH_3)_3{\equiv}COH$, trimethyl carbinol, and characterized by the behavior upon oxidation, thus, (1) primary alcohols yield first **aldehyde,** and upon further oxidation yield **carboxylic acid,** each with the original carbon atom content, e.g., CH_3CHO, **acetaldehyde,** and CH_3COOH, **acetic acid,** (2) secondary alcohols yield initially **ketone** with the original carbon atom content, e.g., $(CH_3)_2CO$, **acetone,** dimethyl ketone, and

SELECTED REPRESENTATIVE ALCOHOLS

Alcohol	Formula	Melting Point (°C.)	Boiling Point (°C.)
*1. Methyl alcohol (methanol)	$H\cdot CH_2OH$	−98	64 5
*2. Ethyl alcohol (ethanol)	$CH_3\cdot CH_2OH$	−117	78 5
3. Normal-propyl alcohol (propanol-1)	$CH_3CH_2\cdot CH_2OH$	−127	98
4. Iso-propyl alcohol (dimethyl carbinol, propanol-2)	$(CH_3)_2CHOH$	−86	82
5. Normal-butyl alcohol (butanol-1)	$CH_3(CH_2)_2CH_2OH$	−90	118
6. Methylethyl carbinol (butanol-2)	$\begin{matrix}C_2H_5\\CH_3\end{matrix}\!>\!CHOH$		99 5
7. Trimethyl carbinol (2-methylpropanol-2)	$(CH_3)_3COH$	25 5	83
Pentanols			
8. Normal-primary-amyl alcohol (pentanol)	$CH_3(CH_2)_3CH_2OH$	−78	138
9. Iso-primary-amyl alcohol (iso-butyl carbinol)	$(CH_3)_2CHCH_2CH_2OH$	−117	130
10. Active-primary-amyl alcohol (secondary butyl carbinol)	$\begin{matrix}C_2H_5\\CH_3\end{matrix}\!>\!CHCH_2OH$		128
11. Tertiary butyl carbinol	$(CH_3)_3CCH_2OH$	53	114
12. Methyl-normal-propyl carbinol	$\begin{matrix}CH_3\\CH_3(CH_2)_2\end{matrix}\!>\!CHOH$		119
13. Methyl-iso-propyl-carbinol	$\begin{matrix}CH_3\\(CH_3)_2CH\end{matrix}\!>\!CHOH$		114
14. Diethyl carbinol	$(C_2H_5)_2CHOH$		116
15. Dimethylethyl carbinol	$\begin{matrix}(CH_3)_2\\C_2H_5\end{matrix}\!>\!COH$	−12	102
Hexanol			
16. Normal-hexyl alcohol	$C_5H_{11}CH_2OH$	−52	156
Heptanol			
17. Normal-heptyl alcohol	$C_6H_{13}CH_2OH$	−35	176
Octanol			
18. Normal-octyl alcohol (caprylyl alcohol)	$C_7H_{15}CH_2OH$	−16	194
Nonanol			
19. Normal-nonyl alcohol	$C_8H_{17}CH_2OH$	−5	215
Decanol			
20. Normal-decyl alcohol	$C_9H_{19}CH_2OH$	47	231
21. Lauryl alcohol (normal-dodecyl alcohol)	$C_{11}H_{23}CH_2OH$	24	250
22. Myristyl alcohol (tetradecyl alcohol)	$C_{13}H_{27}CH_2OH$	38	170 (15 mm)
23. Cetyl alcohol (hexadecyl alcohol)	$C_{15}H_{31}CH_2OH$	49	344
24. Octadecyl alcohol	$C_{17}H_{35}\cdot CH_2OH$	59	
25. Eicosyl alcohol	$C_{19}H_{39}\cdot CH_2OH$	68	
26. Ceryl alcohol	$C_{25}H_{51}CH_2OH$	80	
27. Myricyl alcohol (melissyl alcohol)	$C_{29}H_{59}CH_2OH$	88	
28. Cyclohexanol	$CH_2(CH_2)_4CHOH$	24	162
29. Cycloheptanol (suberyl alcohol)	$CH_2(CH_2)_5CHOH$		185
30. Allyl alcohol	$CH_2{:}CHCH_2OH$	−129	97
31. Crotonyl alcohol	$CH_3CH{:}CHCH_2OH$		118
32. Phytol	$C_{20}H_{37}CH_2OH$		145 (0 03 mm.)
33. Propargyl alcohol	$CH{\vdots}CCH_2OH$	−17	115
34. Furfuryl alcohol	$C_4H_3O\cdot CH_2OH(2)$		170
35. Phenyl carbinol (benzyl alcohol)	$C_6H_5CH_2OH$	−15	206
36. Diphenyl carbinol (benzhydrol)	$(C_6H_5)_2CHOH$	68	299
37. Triphenyl carbinol	$(C_6H_5)_3COH$	162	>360
38. Methylphenyl carbinol	$\begin{matrix}CH_3\\C_6H_5\end{matrix}\!>\!CHOH$		205

(R K.S.)

upon further oxidation yield carboxylic acids or aldehydes containing fewer carbon atoms than the original alcohol, e.g., CH_3COOH, acetic acid plus carbon dioxide, (3) tertiary alcohols yield no product with the original carbon atom content but yield carboxylic acids, aldehydes or ketones containing fewer carbon atoms than the original alcohol, e g, CH_3COOH, acetic acid plus carbon dioxide. Upon reduction of these alcohols (as the haloid compound with magnesium in ether—**Grignard's reagent**—treated with water) the corresponding **hydrocarbons** are obtained, (1) $CH_3 \cdot CH_3$, ethane, methyl methane, (2) $(CH_3)_2CH_2$, propane, dimethyl methane, (3) $(CH_3)_3CH$, trimethyl methane.

By loss of water, directly or by indirect reaction, alcohols form **ethers**, e.g., $(CH_3)_2O$ dimethyl ether, $((C_2H_5)_2O)$ diethyl ether, $CH_2—CH_2$ ethylene oxide (with O bridging the two CH₂ groups),
$CH_2OH \cdot CH—CH_2$ glycide alcohol (O bridging). By the removal of 1 mol of water from ethyl alcohol, **ethylene** is produced.

By reaction with acids, **esters** are formed in great variety.

SELECTED REPRESENTATIVE ETHERS

* Discussed separately under Ether

(R K.S.)

ALCYONARIA. An order of the class Actinozoa in the phylum **Coelenterata.** The animals of this order are marine and because of the hard deposits formed in and around their bodies they are often known as **corals.** Among them are the **sea-pen,** the **sea-fan,** organ-pipe coral, and precious coral.

Alcyonaria are usually found in colonies. The individuals are **polyps** connected together by living structures and by the hard skeletal structures. They differ from the true corals in having only eight tentacles, pinnately branched. (A.W.L.)

ALDEBARAN. Aldebaran (α **Tauri**) is derived from an Arabic phrase indicating that the star is the "leader of the followers," i.e., the leader of the **asterism** known as the **Hyades,** which follow the **Pleiades** in their nightly journey across the sky. Astrologically, Aldebaran was a fortunate star, portending riches and honor. This star was one of the four royal stars of the Persians about 3000 B.C.

Aldebaran is one of the smaller stars whose diameter has been measured with the stellar **interferometer.** The diameter is found to be about 33,000,000 miles, or 38 times the diameter of our sun. (W.K.G.)

ALDEHYDES, KETONES, AND RELATED COMPOUNDS (Acetals, Ketenes). Aldehydes (containing —CHO group) are characterized by a wide variety of chemical reactions, well illustrated by reference to two particular aldehydes, namely, **acetaldehyde** and **benzaldehyde.** Regulated oxidation of primary **alcohols** produces the aldehyde corresponding to the alcohol used, and vigorous oxidation of aldehydes produces the corresponding **carboxylic acid,** thus, ethyl alcohol ($CH_3 \cdot CH_2OH$), to acetaldehyde ($CH_3 \cdot CHO$), to **acetic acid** ($CH_3 \cdot COOH$). Regulated reduction of carboxylic acids produces the corresponding aldehyde, and vigorous reduction, the corresponding primary alcohol—the reverse of the first named reactions. Not only is the range of reaction of aldehydes wide, but also the range of applications, as illustrated under **formaldehyde, acetaldehyde, benzaldehyde, furfuraldehyde.** The reaction with Tollen's solution, as described under formaldehyde, acetaldehyde, benzaldehyde, is commonly used to classify a substance as an aldehyde.

SELECTED REPRESENTATIVE ALDEHYDES

Aldehyde	Formula	Melting Point (°C.)	Boiling Point (°C.)
*1. Formaldehyde (methanal)	$HCHO$	−92	−21
*2. Acetaldehyde (ethanal)	CH_3CHO	−123	20

* Discussed separately under individual name

Ketones (containing =CO group) are in several reactions similar to aldehydes, but less marked than the latter in the variety, as illustrated by reference to the commonest ketone, namely, **acetone**. Regulated oxidation of secondary **alcohols** produces the ketone corresponding to the alcohol used, but vigorous oxidation ruptures the substance with the formation of two acids, one of which is found to be **acetic acid** (CH_3COOH) if a methyl ketone was used. Thus, dimethyl carbinol, isopropyl alcohol ($(CH_3)_2CHOH$) to **acetone** ($(CH_3)_2CO$), to acetic acid (CH_3COOH) plus carbon dioxide (CO_2). Regulated reduction of ketones produces the corresponding secondary alcohol, and vigorous reduction the corresponding **hydrocarbon,** thus being the reverse of the first named reactions. The range of applications of ketones is wide, as illustrated under acetone, **camphor.** The reaction with **hydroxylamine** to form oximes of characteristic melting point, and the absence of acidic characteristics in ketones are commonly used to classify a substance as a ketone.

SELECTED REPRESENTATIVE ACETALS

Acetal	Formula	Melting Point (°C)	Boiling Point (°C.)
1. Methylene dimethyl ether (methylal, dimethoxy methane)	$CH_2(OCH_3)_2$	...	42
2. Ethylidene dimethyl ether (1,1-dimethoxy ethane)	$CH_3CH(OCH_3)_2$	...	64
3 Ethylidene diethyl ether (acetal, 1,1-diethoxyethane)	$CH_3CH(OC_2H_5)_2$	...	104

SELECTED REPRESENTATIVE KETENES

Ketene	Formula	Melting Point (°C.)	Boiling Point (°C.)
1. Ketene	$CH_2:CO$	−151	−56
2. Methyl ketene (in ether solution)	$CH_3CH:CO$		
3. Dimethyl ketene	$(CH_3)_2C:CO$	−98	34
4. Diphenyl ketene	$(C_6H_5)_2C:CO$		265

Acetals are formed by reaction of aldehydes with **alcohols** (or with **carboxylic acids**). The aldehyde is so easily obtained from acetals that the latter may, in certain cases, be conveniently used as a source of aldehyde. With hydrochloric acid heated, the aldehyde and alcohol (or carboxylic acid) are readily formed. Acetals are relatively stable towards alkalis.

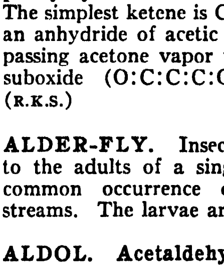
Ketenes are formed along with zinc bromide from alpha-bromo-substituted acetyl bromides by reaction with zinc, e.g., dimethylbromoacetyl bromide ($(CH_3)_2C$ $Br \cdot COBr$) yields dimethylketene ($(CH_3)_2C:CO$). Disubstituted ketenes or ketoketenes are reactive (1) with water, alcohols, ammonia, amines, phenylhydrazine, quinones, forming addition products, (2) with pyridine or quinoline forming ketene bases, (3) with olefin substances forming addition products. Ketenes do not form **phenylhydrazones** or **semicarbazones** as do ketones. The simplest ketene is $CH_2:CO$, which may be considered an anhydride of acetic acid, although it is best made by passing acetone vapor through a red hot tube. Carbon suboxide ($O:C:C:C:O$) is regarded as a diketene. (R.K.S.)

ALDER-FLY. Insecta, Neuroptera. A name given to the adults of a single subfamily of flies from their common occurrence on the alders bordering small streams. The larvae are aquatic. (A.W.L.)

ALDOL. Acetaldehyde.

ALEURITES (Euphorbiaceae). Tropical trees bearing small many-seeded fruits extremely rich in oil. *Aleurites triloba,* the candlenut of the orient, produces a fruit extensively used for food and for light. *Aleurites cordata,* a native of China, is the "varnish-tree." *Aleurites Fordii* yields tung, or nut oil (see **Fixed Oils**), a valuable drying agent used instead of linseed oil, especially in the preparation of waterproof varnishes. It is now widely cultivated in the southernmost parts of the United States. (R.M.W.)

ALEURONE GRAINS. Protein (see **Amino acids and Proteins**) reserves found in the seeds of several different kinds of plants. In many plants there is a special aleurone layer of definite thickness found in the **endosperm.** In **corn** the layer is a single cell in thickness and may contain a colored pigment; in **oats** it is two cells thick. In the **castor oil** plant the aleurone grains are not restricted to a single layer, but are distributed rather generally in the endosperm, and have a complex structure. (R.M.W.)



The aleurone layer in wheat Part of a section of a wheat grain showing aleurone layer with cells filled with granules of protein.

ALEWIFE. Pisces, Teleostei. A common fish (**Pisces**) of the Atlantic coast, *Promolobus pseudoharengus,* related to the herring and shad. It enters the streams to spawn, and is found in lakes of New York. (A.W.L.)

ALEXANDRITE. A variety of **chrysoberyl,** originally found in the **schists** of the Ural Mountains. It absorbs yellow and blue light rays to such an extent that it appears emerald green by daylight but columbine-red by artificial light. It is used as a gem, and was named in honor of Czar Alexander II of Russia. (E.S.C.S.)

ALFALFA. *Medicago sativa.* Lucerne. A leguminous (see **Fruit**) plant probably native in southwestern Asia. It is an important perennial forage plant, which has been extensively cultivated since the Roman civilization. The plant has an extremely deeply-penetrating root system, reaching down 25′ or more, and so is admirably adapted for growing in dry lands, where resistance to drought is important. Its fragrant purplish flowers are an important source of honey, especially in California. (R.M.W.)

ALGAE. (Sea weeds, Pond-scums, etc.) These are **Thallophytes** characterized by possessing chlorophyll, and so capable of elaborating their food by **photosynthesis.** Often the green pigment is completely concealed by other pigments, so that the plant is brown, red, or even black.

Algae are found in almost every habitat. In the oceans vast numbers of minute species float suspended in the upper levels of the water, while the shores are covered with many and varied forms from high tide level to depths of 30′ or more. In fresh water they are equally abundant, but due to their smaller size are seldom so conspicuous as the marine forms; they occur in running water, in ponds, and in stagnant, often putrid water. Many species are found only in hot springs. They are found on the surface of the ground, on the bark of trees, on rocks, and even underground to a depth of several feet. A few species have found a favorable habitat within the bodies of higher plants and animals. In fact, wherever they find support and can obtain the necessary materials for growth, there algae may be found.

Algal plants offer a wonderful diversity of forms. In size they range from unicellular microscopic plants to structures having dimensions comparable to the larger land plants. The plankton forms, those free-floating plants often so abundant in both fresh and salt water, are nearly all unicellular; other free-floating forms, usually found near shore or in small fresh water ponds and streams, are multicellular organisms of various shapes, filamentous forms being especially common. Finally, attached marine forms often attain massive dimensions. The common kelp, or devil's apron, of the colder coastal waters of North America may grow to a length of 30′ or more, and to a width of 2 or 3′, while related species found in the Pacific Ocean far exceed them in size, reaching lengths of 100′ and more.

Not only do algae vary greatly in size, but they also show almost every conceivable shape. Unicellular types are often adorned with a complex but beautifully symmetrical series of arms, or bristles, which may be of service in keeping them floating in the water. The filamentous forms may be simple or very much branched; often they are delicate plants of rare beauty. Other algae grow in flat sheets or membranes, either spreading over the substratum or rising gracefully in the water. The larger forms are of coarser habit, varying from irregular tumorous plants to long slender cords and broad flat fronds. Plants of the genus *Sargassum,* one of the brown algae found in warm regions, have an appearance very similar to that of flowering plants. Each plant has a slender branching stem, often 2′ or more in length. From this stem flat lateral branches arise, which look very much like leaves, except for their brown color. Other short lateral branches end in small sub-spherical balls easily mistaken for fruits. Actually these structures are hollow bladders which help to keep the plant floating. Other branches, the real reproductive parts of the plant, are short cylindrical objects which might be mistaken for buds. At first the plant grows on rocks and other solid objects. It is easily broken loose, however, and floats about in the ocean currents. Thus, these plants are frequently washed up on northern beaches.

There are several systems of classification of algae, varying in details but all using the various pigments found in their cells as a basis for separation. Obviously such a classification is very artificial, but in the algae it seems to agree quite closely with natural systems based on such other criteria as the structure of

the thallus or plant body, as the substances formed by the cells and stored in them, and especially as the reproductive processes which are found in the different groups.

Sargassum linifolium. (*From Altmanns Morphologie und Biologie der Algen, Gustav Fisher, Jena.*)

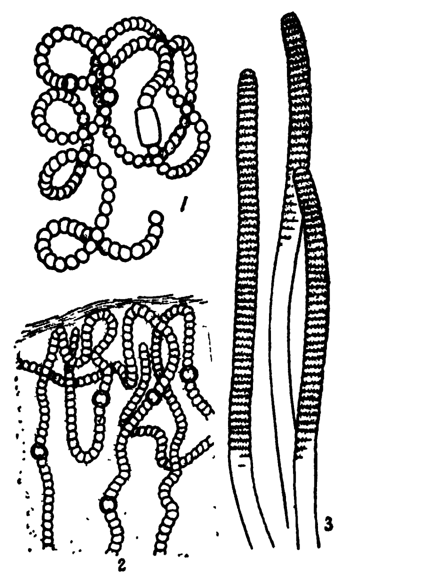
Separated according to pigments the algae fall into four large classes and several smaller ones. The four large classes are the Myxophyceae or blue-green algae, the Chlorophyceae or green algae, the Phaeophyceae or brown algae, and the Rhodophyceae or red algae. The minor classes are the Xanthophyceae (also called the Heterokontae, because of the two unequal cilia (see **Cilium**) which characterize them), the Chrysophyceae, the Bacillariphyceae or **diatoms**, the Cryptophyceae, Dinophyceae, Chloromonadineae and Euglenineae.

The blue-green algae are characterized by having within the cell, in addition to chlorophyll, a bluish pigment, phycocyanin. These pigments are not localized in a definite pigment-bearing body or plastid, but are frequently diffused in the outer zone of **protoplasm.** Surrounding the protoplasm is a definite cell wall of cellulose (see **Carbohydrates**). In most blue-green algae the outer part of the wall is modified and becomes a soft slimy substance which often forms a layer of considerable thickness. This slime substance may be of great value as an insulation against heat and desiccation, thus enabling blue-green algae to live in what seem to be most unfavorable environments. In the central portion of the **protoplast** are found many **chromatin** bodies, which, however, are not organized into a definite nucleus. The structure of the cell of these algae, with its absence of plastids and any definite nucleus, seems to indicate a relatively primitive organism, and is suggestive of the structure found in **bacteria.** Because they reproduce by simple fission, algae and bacteria are sometimes combined into a single group, the Schizophytes.

Many blue-green algae are single-celled organisms. The individual cells are often separate or they may be held together by the gelatinous outer wall in aggregates sometimes of considerable size. Representatives of this group are frequently observed in temporary puddles formed by a summer shower or in quiet shallow ponds in which the water often becomes very warm. Some of them are of considerable economic importance, when they appear in water supply reservoirs. In these they sometimes occur in numbers so great as to color the water and to be only too obvious to the most casual observer. Such occurrences are frequently described as "Water-blooms." Due to the products formed by the metabolism of the cells and liberated into the water, such "blooms" are real problems, for not only do these substances give to the water a distinctly unpleasant oily fishy taste and color, but several cases are recorded in which drinking of such water has been quickly fatal to live stock.

Other blue-green algae occur as simple filaments of cells. Single filaments may occur among other algae or they may exist in extensive masses covering considerable areas with a soft felt-like layer. In some genera many filaments are held together in a common gelatinous sheath. Many blue-green genera show what is called false branching. The rapid division of cells in the middle of a filament causes them to grow out laterally. Sometimes the filaments grow out as a single branch, as in *Tolypothrix,* or in pairs, as in *Scytonema.* True branching is found in a few genera.

In all the non-filamentous species the only method of reproduction is that of **cell division.** In the filamentous forms continued division may produce a filament of in-



Three species of Myxophyceae. 1, Filaments of a species of *Anabaena.* 2, Filaments of *Nostoc* encased in the characteristic jelly. 3, *Oscillatoria.* (*1 after G. M. Smith, 2 after Fremy.*)

definite length. However, it eventually breaks up. This fragmentation may be due to animals feeding on cells of the filament, or to the death of certain cells. In some forms it is due to the development of cells which do not adhere tenaciously to the cells adjoining them. Specialized cells known as heterocysts are largely responsible for the last condition. They are large transparent cells which develop from ordinary cells.

Blue-green algae, particularly abundant in regions having a warm climate, develop elsewhere in great abundance, during the warmer seasons of the year. Besides being a source of trouble in water reservoirs, blue-green algae sometimes form unsightly stains by growing on the walls of stone buildings, especially if the latter be constantly wet. Blue-green algae are of little importance otherwise.

The green algae, or Chlorophyceae, are found in both salt and fresh water, where they often form conspicu-

ous masses. They are characterized by a bright green color. The reserve food stored by these algae is starch, which is usually found around certain bodies known as pyrenoids, located in the **chloroplasts.**

Except that they are an important source of food for many animals, little importance can be ascribed to the green algae. They are, however, of considerable interest because of the possibility that from them the higher plants may have arisen, and because of the diversity of forms which are found within the group.

The protoplasts of the green algae are with very few exceptions enclosed within a rigid wall composed of two layers, an inner made up wholly or largely of cellulose and an outer layer of pectose (see **Carbohydrates**). Within the protoplast of the cell is located one or more conspicuous chloroplasts containing pigments approximately like those occurring in the plastids of higher plants. The chloroplasts of any single genus are usually very constant in appearance but in the different genera remarkable diversity of size and shape obtains. The primitive form seems to be the massive cup-shaped type such as occurs in many lower Chlorophyceae. The nucleus of all green algae is a definitely organized body possessing a nuclear membrane, one or more **nucleoli,** nuclear sap (karolymph), and a chromatin network. Many unicellular forms have one or more cilia which persist throughout their existence. The reproductive cells of most green algae have cilia. (See **Cilium.**)

Reproduction in green algae takes place in various ways. One is a strictly vegetative process in which the colony, or filament, of cells is broken up by various external agents, after which each fragment becomes a new colony, or filament.

Asexual reproduction is by means of cell division (nuclear division followed by division of the cytoplasm) or by zoöspore formation. These zoöspores are generally formed from the protoplast of any vegetative cell, and may appear singly or in numbers by division of a single protoplast. They are expelled from the cell in a manner as yet unknown and are frequently enclosed in a delicate vesicle at the time of expulsion. The zoöspores are naked bodies, having no cell wall, and possessing apical cilia. *Vaucheria* is an exception, for its zoöspores are covered with cilia. After periods of motility varying from a few minutes to many hours, zoöspores become quiescent, withdraw their cilia, secrete a cell wall and develop to new colonies or organisms like the parent form.

Finally, many green algae possess a sexual reproduction which is often very complicated. In sexual reproduction there are formed two sets of reproductive bodies known as **gametes,** which fuse in pairs to form a **zygote.** From the zygote a new plant develops.

The great diversity of form found in the green algae makes them interesting plants to examine for lines of **evolution** which have produced the many forms existent today. Several different lines have been found. One of these includes many of the forms which remain motile throughout their existence. A relatively simple unicellular organism is the starting point for such a line. *Chlamydomonas* is of this type. The plant is a small spherical or oval cell enclosed in a definite cell wall and having two apical cilia. Within the protoplast there is a single massive chloroplast which has a shape like that of a soft rubber ball pushed deeply in on one side. Within the hollow of the plastid the single distinct nucleus is located. At the apex of the cell near the origin of the two cilia there is a minute red body called an eye-spot. This is a light-sensitive organ which when stimulated causes the organism to move toward or away from the light source. In the apical end there is a pair of contractile vacuoles. *Chlamydomonas* reproduces asexually by means of zoöspores. These are formed by divisions of the protoplast to form 2, 4 or 8 daughter protoplasts, contained within the wall of the original cell. This wall softens and liberates these naked cells. At once they become small replicas of the parent cell. They soon grow to the size of the original cell and again form a new group of zoöspores. In a suitable environment this is a very rapid method of reproduction. *Chlamydomonas* also reproduces sexually.

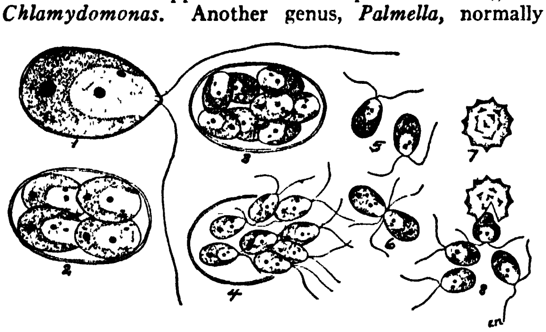
In sexual reproduction the protoplast of the cell divides to form motile bodies called gametes, which are quite like zoöspores, but smaller. On liberation from the parent cell wall, gametes from different cells unite in pairs, and form zygotes which develop into zygospores. A zygospore is a resistant spore with a thick wall which enables the organism to survive periods of adverse conditions. When favorable conditions return, the contents of the zygospore divide to form zoöspores, which behave as do similar spores from motile cells. The similarity of gametes and zoöspores indicates that one is derived from the other, that sex results from the transformation of asexual zoöspores into gametes.

The primitive character of *Chlamydomonas* is found in its contractile vacuoles, its eye-spot, its single massive plastid, and its cilia. From **Flagellates** it differs only in having a definite cell wall. Comparing other motile green algae with *Chlamydomonas* makes it possible to discover an interesting series of species of increasing complexity. First in this series is *Gonium sociale,* with colonies of four cells, and *Gonium pectorale,* with sixteen cells, held together loosely in a gelatinous matrix. All the cells of a colony are alike and any cell may form either zoöspores or gametes. All gametes are alike, but fusion occurs between gametes from different colonies. Next in the line of increasing complexity is *Pandorina,* in which a spherical colony is formed. In this genus the gametes are slightly different in size and behavior, some being small and active, while others, slightly larger, are more sluggish. This is an indication of a differentiation of sex.

Still further advance is shown by *Eudorina,* in which a colony is composed usually of 32 cells located in the peripheral portion of the gelatinous matrix. Each cell of the colony is like a *Chalmydomonas* cell and each is capable of reproducing asexually. But in sexual reproduction a very obvious difference in sexes is apparent. Some colonies are definitely female, the cells enlarging slightly and functioning as eggs. In other colonies, each cell divides to form 64 minute biciliate **sperm.** Fusion between an egg and a sperm produces an oöspore which gives rise to a new colony. In *Pandorina* then a very obvious distinction between sexes has appeared, but the vegetative cells remain alike. In *Pleodorina* each colony is composed of small, purely vegetative cells and larger reproductive cells. The smaller vegetative cells are formed in the anterior end of the colony. In *Volvox* we find the highest degree of differentiation exhibited in this line of motile algae. In this plant the number of cells in a colony is very great, in some species there being as many as 25,000. Of these cells only a few are reproductive, while thousands remain vegetative. Many *Volvox* colonies are so large as to be readily visible to the unaided human eye. In these the many cells form a single layer embedded in the gelatinous matrix. The center of the colony is either water or a thin gelatinous substance. The cells of the colony have the same structure as *Chlamydomonas* cells. They are joined together by fine protoplasmic strands. The beating of the cilia causes the large colony to roll rapidly about in the water, making it a fascinating object to watch. In asexual reproduction certain cells of the colony enlarge and move to the central region. There they lose their cilia, after which they divide rapidly to form new colonies which remain for some time within the parent. Often a single colony will contain a dozen or more of these small colonies. The latter are liberated by the disintegration of the parent colony. In sexual reproduction, cells in the posterior region of the colony differentiate. Some lose their cilia and become very large; these are eggs. Other cells, either in the same

or different colonies, divide many times to form large numbers of minute biciliate sperm. These swim to the eggs. A single sperm enters an egg, its nucleus fusing with that of the egg. As a result a zygote is formed. This secretes around itself a thick wall and becomes an oöspore, capable of enduring protracted periods of unfavorable conditions. With the return of favorable conditions the thick wall of the oöspore breaks, the protoplast emerges and divides rapidly, forming a new colony. *Volvox* represents the climax reached in this line of evolution. There is not only a very great increase in the number of cells forming a colony, but also a distinct separation of vegetative and reproductive cells. The reproductive cells are of two kinds, eggs and sperm. But every cell of the plant retains the primitive character of the individual cell.

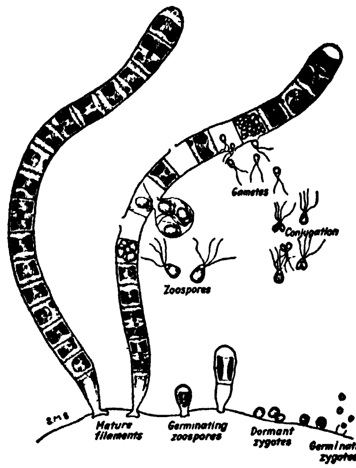
It is possible to build up other evolutionary series of green algae in which the vegetative cells are non-motile. *Chlamydomonas* often assumes a non-motile condition; the cells become embedded in a copious gelatinous matrix and lose their cilia. This condition is known as the palmella stage. *Tetraspora* is an alga which has the appearance of the palmelloid stage of *Chlamydomonas.* Another genus, *Palmella,* normally



Chlamydomonas. 1, Mature cell; 2, Four young cells formed in asexual reproduction; 3, Eight gametes formed by the division of one cell; 4, Gametes escaping from old cell wall; 5, Free-swimming gametes; 6, Two gametes conjugating; 7, Resting zygote; 8, Four cells formed from the zygote. Somewhat diagrammatic.

exists as a shapeless colony of cells held together in a gelatinous matrix. Cilia are lacking, but may be developed by any cell in the colony. A ciliated cell escapes and swims about freely for a time, then settles down and divides to form a new colony. Asexual zoöspores are formed in *Palmella* and also isogametes, that is, gametes of equal size. *Palmella* shows the beginning of a non-motile habit, with a restriction of the motile stages to the reproductive cells. In *Geminella* the amorphous habit of the colony is lost; divisions take place in such a way that the resulting cells tend to exist in a single series, the individual cells being held together only by the gelatinous matrix around them. In *Ulothrix* further advance is made. In this plant the protoplast of the cell divides within the wall of the cell. But it does not escape therefrom; instead cross-walls are formed between daughter protoplasts which remain permanently joined. Repeated divisions in a single direction result in the formation of a long unbranched filament of cells. Asexual reproduction in *Ulothrix* is by zoöspores. These are very similar to the cells of *Chlamydomonas,* but each has 4 cilia. From each zoöspore new filaments are formed directly. Sexual reproduction is by biciliate gametes which are formed in the usual manner. Two gametes fuse to form a *zygote,* which develops a thick wall, becoming a zygospore, and on germinating produces zoöspores. In some species of *Ulothrix* the gametes are alike, while in others slight differences in size of the gametes produced from different cells indicate the beginning of sex differentiation.

Other genera of algae, related to *Ulothrix,* show greater differentiation in the vegetative cells. Branching occurs in many; certain cells produce the zoöspores or gametes. Other genera, notably the marine *Ulva,* the Sea Lettuce, have cell divisions in two planes, so



Ulothrix. Stages in development.

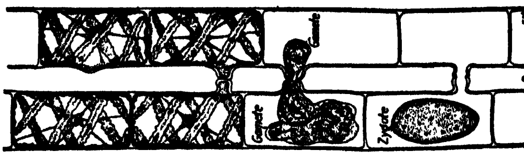
that extensive membranes are formed, often two meters or more in length.

The highest stage of development in this series is found in *Coleochaete.* This alga appears as small disks epiphytic on other aquatic plants. It consists of branching filaments which in some species grow out to form a flat shield-like thallus. Asexual reproduction is by biciliate zoöspores, which are formed singly from the protoplast of any cell. In its sexual reproduction, *Coleochaete* is especially interesting, exhibiting an advanced degree of differentiation of sex cells called oögamy. The eggs are formed in special cells at the tips of certain filaments. By continued growth, the vegetative cells form a layer enclosing the oögonium. From the oögonium a projection called the trichogyne grows out; in some species it remains short, but in one at least it becomes long and slender. The biciliate sperm are formed singly in special cells known as antheridia. A single sperm enters the egg through the trichogyne or papilla, through a soft place which forms in the wall. Following fertilization, or the union of egg and sperm, the fertilized egg enlarges greatly and secretes around itself a thick wall, in which condition it remains very resistant to external changes. On germination its contents divide to produce 16 or 32 cells, each of which produces a zoöspore. These give rise to new plants. In *Coleochaete* we have a highly developed end product to an advancing degree of differentiation of cells and development of sex.

Many other equally interesting lines of evolution can be found in green algae. One leads to *Vaucheria,* a branching filamentous plant in which cross walls are not formed, nuclear divisions occurring until an extensive multinucleate filament is formed. Many marine relatives of *Vaucheria,* especially abundant in tropical seas, have elaborate bodies, often thickly encrusted with lime. In the genus *Caulerpa* the thallus of some species appears to be differentiated into leaves, stems and roots; however, no differentiation of tissue occurs, the whole structure being essentially filamentous.

Another group of algae, found only in fresh water, is the Conjugales. This includes the frequently observed *Spirogyra,* a genus having spiral chloroplasts. Sexual reproduction in *Spirogyra,* as in all the Conjugales, is by a process called conjugation. When the cells of two filaments are to conjugate they come into contact one with another. From the cells of one filament projections grow outward to meet similar projections from the cells of the other filament. These projections meet, and the walls at their tips are absorbed, leaving a tube connect-

ing two cells of opposite filaments. Through this tube the protoplast of one cell moves into the opposite cell, where fusion occurs. Following this the zygote thus formed surrounds itself with a thick wall. This zygospore is extremely resistant to unfavorable external conditions, such as drought. After a prolonged rest period, if environmental conditions are favorable, the



Spirogyra. Stages in conjugation.

wall of the zygospore breaks, and a tube grows out from the protoplast within. By divisions, this tube becomes a new filament. Observation of conjugating filaments of *Spirogyra* reveal two facts: first, that when one cell of a filament conjugates with a cell of another filament, commonly all the cells of the first filament are conjugating with those of the other; second, that movement is largely from one filament to the other, so that at the end of the process one filament is composed of empty cell walls and the other filled with zygospores. This may be conceived as a sexual condition, the empty cells having been male and the cells in which the zygospores formed, female. Many related algae in the Conjugales show no indication of sexuality, the protoplasts uniting in the tube joining the two cells. No ciliated cells of any sort occur in this order.

Related to *Spirogyra* is a family containing many species whose cells are very symmetrical and beautiful objects. This is the Desmidiaceae, a family whose members commonly occur as single cells composed of two symmetrical halves. In many species the halves are distinctly indicated by a deep constriction which leaves only a slender isthmus connecting them. Conjugation in the Desmids is essentially like that in the other Conjugales.

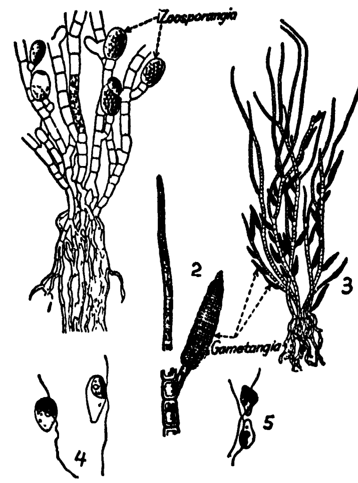
The brown algae, or Phaeophyceae, are distinguished from other algae by the presence of the brown pigment fucoxanthin, which masks the chlorophyll present and which imparts to them a brown color. They are nearly all marine plants. In this group there are no very simple primitive forms, comparable to *Chlamydomonas* of the greens. The simplest forms, such as *Ectocarpus,* are branched filamentous plants

Other brown algae are very large, with tough bodies of many often complex shapes. They are most numerous on rocky coasts, where they grow attached to the rocks and are often exposed to the severest pounding of the tides. Brown algae are found in all regions, but are especially abundant in the cold temperate and arctic waters. One genus, *Sargassum,* occurs in great abundance floating in the Atlantic Ocean, forming the Sargasso Sea, through which Columbus passed so slowly on his voyage of discovery. Probably these plants are carried by ocean currents from the shores where they grow to the Sargasso Sea, where they float endlessly. The brown algae include the largest plants of this division of the plant kingdom, many of the kelps growing 30–40′ long, and some of the plant forms of the Pacific Ocean attaining lengths of a hundred feet and more.

All brown algae are multicellular plants. Each cell contains a single distinct nucleus and several chloroplasts which contain chlorophyll, carotin, xanthophyll and fucoxanthin. The presence of the latter hides the other pigments. **Photosynthesis** in brown algae, as in other plants, results in the formation of sugar. This sugar however is changed into a compound, laminarin, instead of starch, which is never found in this group of algae.

The Phaeophyceae are divided into several orders. These show interesting differences in their life histories. In most of them there is a very definite alternation of generations. Plants of the sexual generation form gametes; the asexual generation forms zoöspores. The motile cells of the brown algae are quite distinct from those of the green algae, having 2 unequal cilia which are attached laterally and extend in opposite directions.

One of the orders of this class is the Ectocarpales, of which *Ectocarpus* is a common form. It occurs as soft



Ectocarpus.

Ectocarpus. Stages in development. 1, Sporophyte plant; 2, 3, Gametophyte plants; 4, Two zoospores; 5, Conjugation of gametes to form zygotes. (*Reprinted by permission from Textbook of General Botany, by Holman & Robbins, published by John Wiley & Sons, Inc.*) (*After Setchell, & Gardner.*)

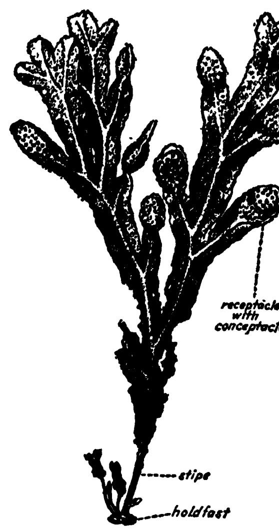
brown tufts growing on other larger algae or on stones or woodwork in the water. Each plant is composed of slender branching filaments. In this genus there is a definite alternation of two generations which are indistinguishable in the vegetative condition. Plants of the sexual generation are haploid, that is, have the reduced number of chromosomes and bear gametangia. These are elongated structures composed of many small, cubical cells. Each of these cells forms a single gamete. The plants of this generation and the gametangia they bear all look exactly alike. The gametes which they produce also look very much alike. But in behavior they are different. Some are sluggish, moving but little, while others swim actively and are attracted to the sluggish ones from other plants. The active gametes are males, the others females; sometimes the female gametes are slightly larger than the males. One male gamete fuses with a female, forming a zygote. The zygote always forms an asexual plant which is **diploid**. There are two kinds of asexual plants, which look exactly alike, and also like a sexual plant. Each forms zoösporangia. One form of zoösporangium, called a plurilocular zoösporangium, is composed of many small cubical cells, each of which forms a single zoöspore. These zoöspores are liberated, swim about for a time, sink to the bottom and settle against any solid substratum and give rise to new asexual plants of the same type as that producing them. The other type of zoösporangium, often found on the same plant as the first, is composed of a single, usually much-enlarged, cell. The protoplast of this cell divides many times and gives rise to several zoöspores which are haploid. Therefore reduction division takes place in the sporangia, which produce these zoöspores. These zoöspores produce sexual plants. In some species of *Ectocarpus* the alternation of generations is not as regular as that described.

Another order of brown algae is the Cutleriales, of which the genus *Cutleria* is a well-known example. In *Cutleria* the two generations have a very different appearance, the sexual plants being much branched, and

several inches tall, while the asexual plants are small lobed thalli growing prostrate on the substratum. So different are these two generations that they are often mistaken for different plants. The sexual plants are of two kinds, male and female, which differ very little. The sex organs are borne on the surface of the thallus. The male gametangia are elongate structures borne on branching filaments; the female gametangia are stouter and composed of few cells. The male gametes are minute and biciliate, the female, also biciliate, are many times larger. Many male gametes swim to a single female, one fuses with it, producing a zygote. The zygote develops into an asexual plant. The zoöspores, formed from small sac-like zoösporangia, which develop in large numbers on the upper surface of the thallus, are biciliate and very similar to gametes. They form sexual plants. In this order there is a very distinct difference in the two gametes, male and female, and a striking difference between sexual and asexual plants.

A third order is the Laminariales, which includes the largest algae known, commonly known as kelps. Some of them have a very striking appearance. *Postelsia*, for example, has a plant body composed of an erect stiff stalk often several inches in diameter. From its base many thick root-like outgrowths spread out and fix the plant firmly to the substratum. At the top of the stalk, long spreading branches are found. When the plant is seen growing in water it has much the appearance of a palm tree, whence the common name, sea palm. Another plant in this order is *Chorda filum*. Its thallus is a tough cord-like object 3–8′ long and about $\frac{1}{4}''$ in diameter. It looks very much like a coarse round leather shoestring. A very common genus is *Laminaria*, which has many species of various forms, mostly large. Some of them consist of long cord-like stalks which bear at their upper end a broad flat expansion often 6–12′ long and 8–15″ broad. Colloquially these are known as devil's aprons. These large plants are the asexual generation and so are diploid. The zoösporangia are formed in immense numbers on the surface of the thallus. Each zoösporangium is a cylindrical object which produces many small biciliate zoöspores. These zoöspores swim down to the sea bed, where they develop into haploid or sexual plants. The latter are minute, usually consisting of a few cells which form a branching filament. Some of the plants are male, others female. In the female plant, any cell may become a sexual cell; often the plant is only a single cell. This sexual cell is an oögonium and forms a large non-motile egg which remains in the parent plant. Any cell of the male plant may become sexual, producing minute biciliate sperms which swim to the egg and fuse with it, forming a zygote. The latter at once develops into an asexual plant. In this order, there is also a distinct alternation of generations, but the sexual generation contains the small plants, the asexual usually very large plants. The sexual cells are distinctly different: the large non-motile egg and the small biciliate sperm.

A fourth order of brown algae is the Fucales. Members of this order are tough, much-branched plants which are particularly abundant between the tide levels on rocky shores in regions where the water is cold. *Fucus*, the common rockweed or bladder wrack, is a common and well-known plant. In this, as in all members of this order, there is no asexual reproduction. Therefore no distinct alternation of generations can occur. A *Fucus* plant consists of a tough dichotomously branched frond, which is attached to the rock on which it grows by a disk-shaped holdfast. In many species hollow bladders develop along the frond and serve to bring the plant into an erect position at high tide. At the tips of the branches of the thallus the reproductive bodies, receptacles, are formed. In some species these tips are swollen to form hollow bladders, in others they are flat and little differentiated from the rest of the thallus. The reproductive cells are formed in spherical cavities which are connected with the surface by small pores. Each cavity is called a conceptacle. Numerous branching filaments rise from the lower part



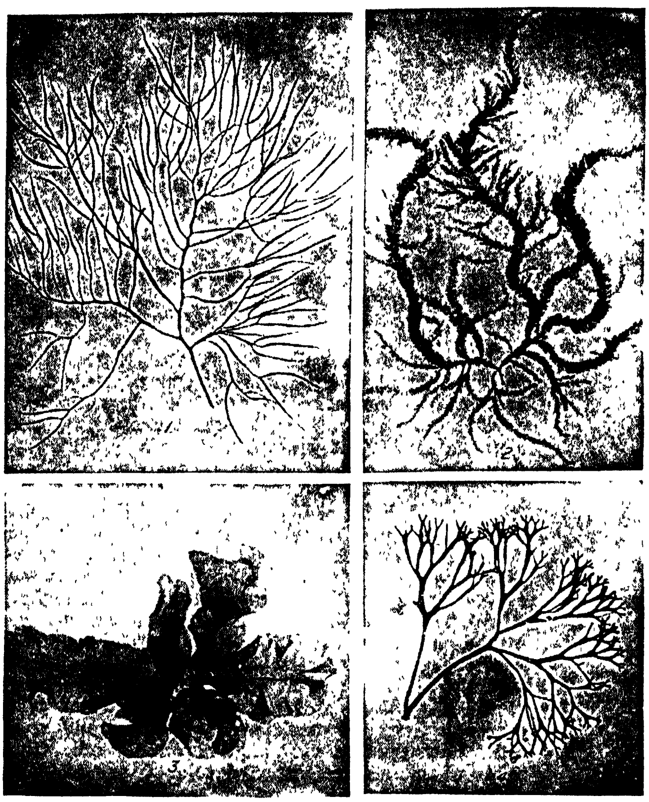
Fucus. Mature plant, $\times \frac{1}{3}$. No bladders are shown. (*From Morphologie und Biologie der Algen, Gustav Fischer, Jena.*)

of the conceptacle wall. Branches of these filaments bear the sexual organs. In some species the two sexes are borne in the same receptacle, in others they occur on different plants. The male sex organs or antheridia are oval sacs. The protoplast of each sac divides to form 64 cells, each of which becomes a laterally biciliate sperm. When mature these antheridia are extruded through the ostiole or opening of the conceptacle into the water. There the wall of the antheridium bursts, liberating the sperms. Each oögonium consists of a single cell. Its protoplast divides to form eight eggs. These also are extruded from the conceptacle, while still within the wall of the oögonium, and freed by the bursting of the same. Both types of conceptacle secrete a gelatinous matrix which surrounds the oögonia or antheridia and aids in bringing them to the surface of the receptacle. This matrix is squeezed out of the conceptacles by the partial drying of the frond at low tide. Each egg is a very large non-motile cell. Thousands of sperms are attracted to each egg and swim about it, causing it to revolve rapidly. Finally one sperm gains entrance to the egg and fertilizes it. The other sperms immediately swim away. The fertilized egg settles to the bottom, attaches itself to the substratum and at once starts to develop into a new plant. In the Fucales there is no alternation of generations. The gametes of the Fucales are very distinct, one being a large non-motile egg, the other a very small swimming sperm. One is tempted to arrange the various orders of brown algae in a series showing the way in which each may have evolved. However, such evolutionary relationships are purely speculative and not supported by any real evidence. It is impossible to trace the ancestry of the brown algae back to any simple ancestor, since no simple forms of brown algae are known.

The economic importance of the brown algae, while slight, is much greater than that of the green algae. Large quantities of these plants are gathered and used for fertilizer, wherever agriculture is carried on near the coast. From the ash produced by burning the larger forms, the kelps and Fucales, iodine and also potassium are obtained. In the Orient and in some of the north Atlantic islands, some of the brown algae are used as food, both for human beings and for live stock.

The red algae or Rhodophyceae form a very large group of plants, nearly all marine, of small to medium size. They are particularly abundant in warm coastal waters and are often plants of great beauty and extremely delicate habit. The red color to which they owe their name is caused by phycoerythrin, a red pigment which is present with the common chlorophyll-carotin group of pigments. These pigments are present in definite bodies or plastids, and not diffused through the protoplasts, as in the blue-green algae.

The forms of red algae are numerous. In many species the thallus is an extremely delicate filament. In other species the thallus is a tough, branched body 6–15″ long. Others are flat membranes which may be a single cell in thickness or may be many cells thick. Some are thickly covered with a calcareous deposit, so that they are hard and stony, resembling corals. No motile reproductive cells are produced by members of this group. In sexual reproduction there is always a large female cell which is fertilized by a small male cell. This sexual reproduction is a rather complicated process. The antheridia are single-celled bodies; in some species the whole cell is liberated, in others the protoplast of the antheridium is freed. In either case the male cell floats in the water, carried only by the currents. The female reproductive organ is known as the procarp. In simpler forms this consists of a swollen basal portion called a carpogonium and a long slender portion called a trichogyne. Chance brings the male cell to the surface of the trichogyne, against which it sticks. The wall of the trichogyne is dissolved, allowing the nucelus of the male cell to enter the trichogyne. This nucelus passes down the trichogyne and enters the carpogonium, where it fuses with the female nucleus. From the fertilized carpogonium asexual spores called carpospores are formed, usually at the ends of branches which grow out from the carpogonium or from cells which are formed from those surrounding the carpogonium. Into these carpospores, nuclei from the carpogonium pass. The carpospores of simpler red algae at once produce sexual plants. In most red algae, however, they produce asexual plants which may be identical with the sexual plants in appearance. These asexual plants bear reproductive cells called tetraspores, because 4 of them are borne in a single sporangium. Each tetraspore gives rise to a sexual plant. So in the majority of red algae there is a distinct alternation of generations.



Four red algae. 1, *Agardhiella tenera;* 2, *Dasya elegans;* 3, *Grinellia americana;* 4, *Chondrus crispus.* × ⅓. (*Photographs of herbarium specimens by Naylor.*)

Of the many species of red algae very few are of any importance. In northern waters of both coasts of the Atlantic, dulse, ***Rhodymenia palmata,*** is found. It is gathered, cleaned more or less, and dried. It is then sold as a food or a relish. Species of ***Porphyra,*** often called laver, are also eaten, especially by Oriental people. Irish moss, or corrageen, which is ***Chondrus crispus,*** is another red alga which is gathered for food. It is a small much-branched plant, commonly dark red in color and with a beautiful iridescent surface. The plants are gathered, thoroughly cleaned and dried. Drying bleaches them to a creamy white color. When thoroughly dry they are bagged and sold. The powdered plant is commonly boiled in milk, flavored and sweetened, and allowed to cool. It forms a firm smooth gel known as blanc-mange. From species of red algae growing in the Pacific Ocean, **agar agar** is obtained.

The origin of the red algae and their relationships with other algae is a matter of considerable speculation. A few trace them from the blue-green algae, finding in some of the more primitive red algae "connecting links" which support this view. There are no ciliated reproductive cells in either of the two groups. But their distinct well-developed nucleus, their plastids, and their complex reproductive process set the red algae off very clearly. In view of these facts, it is perhaps more logical to derive the red algae from the green, using a form like *Coleochaete.* If there is any relationship between the red and the blue-green algae, it must be rather remote. (R.M.W.)

ALGAL REEFS. **Paleobotany.**

ALGEBRA. As generally understood in an elementary sense, algebra is a branch of mathematics which deals with the operations with **numbers** by means of general symbols, such as letters, and with some of the simpler applications of these operations.

For the historical origin of algebra, we must go back to the time of the early Egyptians. The germs of algebra are found in the ancient papyrus of Ahmes (about 1700 B.C.). The ancient Greeks developed elementary **geometry** to a remarkable degree, but occupied themselves very little with algebra. It was not until the time of Diophantus (about 300 A.D.) that any Greek work in algebra was done to amount to anything. The early Hindus, however, cultivated elementary algebra to a surprising extent, but were little concerned with geometry.

The origin of the name "Algebra" is somewhat obscure. The Arabic mathematician ***Mohammed ibn Mûsâ al-Khowârizmî*** (about 825 A.D.) wrote a work entitled "*Al-jebr w'al-muqâbalah,*" which is sometimes translated as "restoration and equation," but the meaning is not exactly clear. This work treated of algebraic topics and its name is generally considered to have been the

source of the name algebra. The modern Europeans became acquainted with algebra from the Arabs.

Some indication of the subject-matter usually considered as belonging to algebra may be found by consulting the following topics: **Number, Algebraic Operations, Algebraic Expressions, Factoring, Fractions, Involution, Evolution, Powers and Exponents, Radicals, Identities, Equations, Solution of Equations, Linear Algebraic Equations, Quadratic Equations, Polynomial Equations, Graphs, Inequalities, Binomial Formula, Logarithms, Progressions, Variation, Permutations, Combinations, Prbability, Determinants.** (L.L.S.)

ALGEBRAIC EQUATIONS. An algebraic equation is an **equation** in which both members are **algebraic functions.**

Algebraic equations in one unknown are classified into **polynomial equations** (rational integral equations), **fractional equations, radical** or irrational **equations;** polynomial equations are classified further. (L.L.S.)

ALGEBRAIC EXPRESSIONS. An algebraic expression is a symbol or combination of symbols that represents a number. If the expression consists of two or more parts connected by plus and minus signs, each of these parts with the sign preceding it is called a term. A monomial is an algebraic expression consisting of only one term, a polynomial is one consisting of more than one term; a binomial and a trinomial are polynomials of two or three terms respectively.

If two or more numbers or number symbols are multiplied together, each of them is called a factor of the product. Any factor of a product may be called the coefficient of the remaining part. (L.L.S.)

ALGEBRAIC FUNCTIONS. An algebraic function is a **function** which involves the **variable** in only the operations of **addition, subtraction, multiplication, division,** raising to **powers** with constant rational exponents, and extraction of roots (**involution**), a limited number of times.

An algebraic function may also be defined as a function $y = \phi(x)$ which satisfies an equation of the form $f(x,y) = 0$, where $f(x,y)$ is a **polynomial** in x and y.

Algebraic functions are classified into **rational functions** and **irrational functions,** and **power functions;** rational functions are further classified into sub-classes. (L.L.S.)

ALGEBRAIC NUMBERS. An algebraic number is a **number** which satisfies a **polynomial equation** in one variable with integral coefficients. (L.L.S.)

ALGEBRAIC OPERATIONS. Algebra is concerned with **numbers** and with various operations with numbers. The fundamental operations of algebra are: **addition, subtraction, multiplication** and **division.** Two other derived operations are **involution** (raising to a power), and **evolution** (extraction of roots). (L.L.S.)

ALGIN. A hydrophilic colloidal polysaccharide obtained from *Macrocystis pyrifera* and other species of **brown algae.** The term is used both in reference to the pure substance, alginic acid, extracted from the algae and also to the salts of this acid such as sodium or ammonium alginate, in which forms it is used commercially. The alginates currently find a large number of applications in the paint, rubber, pharmaceutical, food, and other industries. (B.S.M.)

ALGOL. Algol (**β Persei**) is one of the first **variable stars** to be recognized as such. The first scientific notice of this variability was made by Montanari in 1670, but it is quite evident that the changes in the light of this star were noticed long before this time. In fact, the very name Algol, which signifies "Demon star," was probably assigned to the star because of its peculiar behavior. **Astrologically,** Algol was considered the most unfortunate star in the heavens.

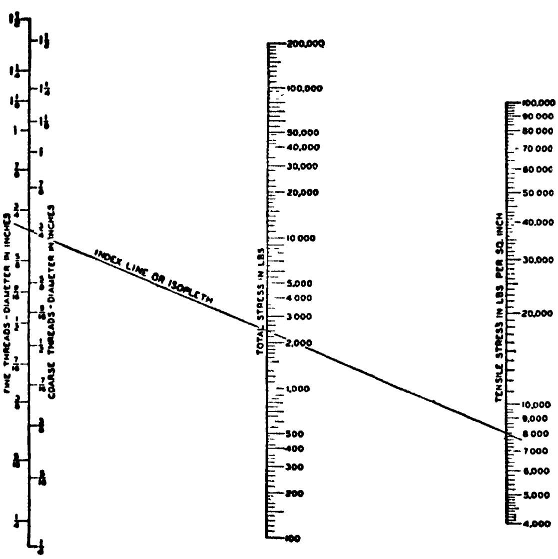
Algol is an **eclipsing binary** and is the first star of this type to be explained. Because of its great brightness it has been extensively observed with all types of stellar **photometers** and the characteristics of its **light curve** are known with great precision. Algol is also a **spectroscopic binary,** and, from the determination of the **orbital elements** from the light variability as well as from the spectroscopic data, the physical characteristics of the component parts may be determined. (W.K.G.)

ALGONKIAN. A term applied to rock formations of late pre-Cambrian (**Proterozoic**) date in the Great Lakes region, and to the unit of time represented by these formations. Some American geologists use the term as a synonym for late pre-Cambrian. (See **Historical Geology.**) (R.M.F.)

ALIDADE. Plane Table.

ALIENIST. A legal term applied to a specialist trained in neurology and psychiatry who testifies in court on questions concerned with mental disease. (D.M.H.)

ALIGNMENT CHART. Nomograms or calculating charts used to represent formulae containing three or more variables. Graduated lines represent the variables;



an index line or isopleth passing through points of two scales of known values will intersect the third scale to give the solution of the problem. The nomogram shown will give the solution of the equation $0.785D^2S = T$, where D is the root diameter of an American Standard screw, S is the unit tensile strength, and T is the total stress. (H.C.H.)

ALIMENTARY TRACT. The structures through which nourishment pass during the process of digestion and elimination. These include the mouth, pharynx, esophagus, stomach, the small intestine, which includes **duodenum, jejunum,** and **ileum,** and the large intestine, which includes the cecum, **colon, rectum** and **anus.** (See also **Anatomy; Digestive System.**) (R.S.M.)

ALIZARINE. **Dyes.**

ALKALI RESERVE. **Acidosis.**

ALKALI ROCKS. Igneous rocks which contain a relatively high amount of alkalis in the form of soda **amphiboles,** *soda* **pyroxenes,** or **felspathoids,** are said to be alkaline, or alkalic. Igneous rocks in which the proportions of both lime and alkalis are high, as combined in the minerals, **feldspar, hornblende,** and **augite,** are said to be calc-alkali. (R.M.F.)

ALKALIS. **Acids, Bases, and Salts.**

ALKALOIDS. Alkaloids are types of organic bases. They are generally colorless, odorless solids, of definite melting point, which decompose upon attempted distillation, of bitter taste (poisonous), insoluble in water, soluble in alcohol, ether, chloroform, carbon tetrachloride, amyl alcohol, benzene. Alkaloids are generally related to nitrogen ring compounds, e.g., **pyridine, quinoline, isoquinoline, pyrrole, pyrrolidine, purine,** and are found in certain plants (*Papaveraceae, Leguminosae, Ranunculaceae, Solenaceae, Rubiaceae* (cinchona). They are powerful poisons, many possess high medicinal value, some are habit-forming. Alkaloids of plants are usually found as alkaloid salts of **carboxylic acids,** e.g., of malic, citric, oxalic, succinic, quinic (**cinchona** alkaloids), meconic acid (**opium** alkaloids), in all parts of the given plant, but are generally accumulated in the fruit, seeds or bark. Alkaloids react as bases to form salts (especially used for crystallization purposes are **hydrochlorides, sulfates, oxalates**), which are generally soluble in water or alcohol, insoluble in **ether, chloroform, carbon tetrachloride, amyl alcohol.** Alkaloid salts unite with **mercury, gold,** and **platinum** chlorides. Free alkaloids lack characteristic color reactions but react with certain reagents, as follows, with (1) **iodine in potassium** iodide solution, forming chocolate brown precipitate; (2) **mercuric** iodide in potassium iodide solution (potassium mercuriïodide), forming precipitate; (3) potassium **bismuth** iodide, forming orange-red precipitate; (4) **bromine-saturated hydrobromic acid** concentrated, forming yellow precipitate; (5) **tannic** acid, forming precipitate; (6) phosphomolybdic acid, forming precipitate; (7) phosphotungstic acid, forming precipitate; (8) auric chloride, forming **crystalline** precipitate of characteristic melting point; (9) platinic chloride, forming crystalline precipitate of characteristic melting point; (10) **picric acid,** forming precipitate; (11) **perchloric acid,** forming precipitate.

It should be noted that these reagents precipitate some organic substances other than alkaloids. The majority of the free alkaloids are optically active, and laevorotatory, but an appreciable number are inactive or dextrorotatory. Alkaloid salt solutions are often different in sign and value of rotatory power from the free alkaloid, and the value is sometimes affected by the nature of the solvent and by the concentration. Alkaloids are usually extracted from the plant material by hydrochloric or sulfuric acid. This extract is then made slightly alkaline, thus precipitating the free alkaloid base, which may be separated by filtration and purified by further crystallization. It was suggested by Pictet as early as 1905 that the methylation (formation of —CH_3 group) of hydroxyl (—OH) or amino (—NH_2) groups, occurs in the plant by means of formaldehyde (HCHO), followed by rearrangement in which the methyl group enters the ring, thus increasing the ring by one additional carbon:

Pyrrole, by formaldehyde, into 1-methylpyrrole, rearranging into pyridine.

Indole, by formaldehyde into 1-methylindole, rearranging into quinoline.

More recently Robinson conducted the reaction of formaldehyde with 2,5-diaminopentanoic acid ($CH_2NH_2 \cdot CH_2 \cdot CH_2 \cdot CHNH_2 \cdot COOH$) obtaining 1-methyl-2-hydroxypyrrolidine plus ammonia plus carbon dioxide. (See table, p. 45). (R.K.S.)

ALKALOSIS. **Acidosis.**

ALKYL. **Radical** of aliphatic **hydrocarbon.** (R.K.S.)

ALLANITE. Allanite is a rather rare **monoclinic** mineral of somewhat variable but quite complex chemical composition, perhaps represented satisfactorily by the formula $Ca_2(Al,Ce,Fe)_2(Al \cdot OH)(SiO_4)_3$. The color of the fresh mineral is black but it is usually brown or yellowish with a coating of some alteration product; often the altered crystals have the appearance of small rusty nails. It occurs characteristically in plutonic rocks like **granite, syenite** or **diorite** and is found in large masses in **pegmatites.** Localities in the United States are Essex and Orange Counties, New York, Franklin, New Jersey, Amherst County, Virginia, and Llano County, Texas. The slender prismatic crystals are sometimes called orthite. Allanite was named for its discoverer, T. Allan. Orthite was so named from the Greek word meaning straight, in reference to the straight prisms, a common habit of this mineral. (E.S.C.S.)

ALLANTOIN. **Alkaloids.**

ALLANTOIS. A sac-like outgrowth of the hind gut of the **embryo** found only in **reptiles, birds** and **mammals.** In reptiles and birds it serves as a respiratory organ and receives waste matter, and in mammals it forms part of the **placenta** through which all interchange with the blood of the mother during embryonic development is carried out. (A.W.L.)

ALL-DAY EFFICIENCY. In some applications of equipment, the load varies widely during the day and the machines have a no-load loss plus an additional loss which varies with the load. Hence the *efficiency* will vary from time to time during the day. The all-day efficiency is an over-all picture of the varying efficiency and is defined as the total energy output multiplied by 100 and divided by the total energy input in a day.

$$n = \frac{p_1t_1 + p_2t_2 + \cdots}{P_1T_1 + P_2T_2 + \cdots} \times 100$$

where p_1, p_2, etc., are the various output powers, and t_1, t_2, etc., are the corresponding times of use, while P and T represent the input powers and times. (L.R.Q.)

ALLELE, ALLELOMORPH. In Mendelian inheritance (see **Heredity** and **Evolution**), contrasting pairs of characters, as tall and dwarf, or the contrasting genes which produce them, are known as alleles or allelomorphs. The new term, allele, is preferable. (R.M.W., B.S.M.)

ALLERGY. The state of exaggerated susceptibility to a substance which is harmless in similar or greater amounts to most individuals. A person exhibiting this is said to be allergic to the substance causing the reaction. These substances are usually of **protein** nature, although physical agents such as heat, cold, and light can provoke an allergic response. The principal diseases of allergy are serum disease, serum accidents, **hay-fever, asthma, angioneurotic edema,** and **hives.** (R.S.M.)

ALLIGATOR. Reptilia, Crocodilia. A large freshwater **reptile.** Two species are known, one in China, *Alligator sinensis,* and the other, *A. mississippiensis,* in the southern United States. The American alligator, larger of the two, reaches a length of 16′ and a weight of 500 lbs. It has been hunted to some extent for its skin, which makes durable leather. (A.W.L.)

SELECTED REPRESENTATIVE ALKALOIDS

Alkaloid	Formula	Melting Point °C.	Boiling Point °C.
1. Aconine	$C_{25}H_{41}NO_9$	132

*55. Veratridine	$C_{36}H_{51}NO_{11}$	180	
56. Xanthine	$C_5H_4N_4O_2 \cdot H_2O$	150 decom.	

(R K.S)

* See Purine and Uric Acid Compounds.

ALLIGATOR PEAR. **Avocado.**

ALLIUM. Liliaceae. A large genus whose species are found widely. Some 75 species are found in North America, especially in the western states. All are bulbous plants with flat or tubular leaves, and with spherical heads or umbels of variously colored flowers. Particularly important cultivated species are the onion, *Allium Cepa;* leek, *Allium Porrum;* garlic, *Allium ursinum;* and chives, *Allium Schoenoprasum.* One European species now extensively introduced in the United States is the field garlic, *Allium vineale,* which (if eaten by cows) noticeably flavors milk and butter. (R.M.W.)

ALLOCHTHONOUS. A term proposed by Gümbel in 1888 for **sedimentary** rocks whose constituents have been transported and deposited at some distance from their place of origin. The bulk of the sedimentary rocks are of this type. The term is now used most commonly in reference to masses of rock transported considerable distances by tectonic movements. (See **Overthrust.**) (R.M.F.)

ALLOPALLADIUM. **Iridosmine.**

ALL-OR-NONE LAW. A principle of reaction in living matter under which a structure responds to a stimulus to the maximum degree possible in its existing physiological state, regardless of the strength of the inciting stimulus. Thus any stimulus capable of exciting a nerve cell at a given moment will arouse the same degree of activity in that cell. First demonstrated by Bowditch for heart muscle, this principle has since been found applicable to single neurons and single muscle fibers when stimuli similar to those occurring in nature are applied. (A.W.L.)

ALLOTRIOMORPHIC. A term proposed by Rosenbusch in 1887 for minerals in **igneous** rocks which are not bounded by their typical **crystal** faces. Such minerals are said to be anhedral. (R.M.F.)

ALLOTROPES. **Chemical Composition.**

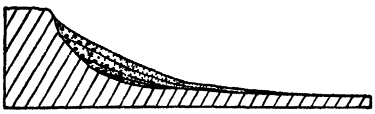
ALLOTYPE. An animal or plant fossil selected as a species or sub-species as illustrating morphological details not shown in the **holotype.** (R.M.F.)

ALLOWANCE. **Interchangeable Manufacturing, Fit.**

ALLOYS. **Metals and Alloys.**

ALLSPICE. *Pimenta officinalis.* Myrtaceae. Allspice is the dried fruit of a small tree native in the West Indies and Central America. The tree grows to a height of 30 or 40′, has leathery leaves, fragrant with the oil they contain, and small white flowers borne in axillary cymes (see **Flower**). The fruits contain one or two seeds. Before they are ripe the fruits are gathered, rapidly dried and marketed under the name allspice. This name was given because early users thought the flavors of **cinnamon, cloves** and **nutmeg** were all found in this one spice. It is used for flavoring cakes, puddings and pies. (R.M.W.)

ALLUVIAL FAN. Also termed subaerial delta. Cone-shaped to delta-shaped deposits of coarsely graded **clastic** sediments deposited by intermittent streams that



Cross-section of an alluvial fan, or sub-aerial delta. (*Field, Laboratory Manual, Princeton University Press.*)

debouch from steep valleys onto a relatively gentle slope or plain. Alluvial fans may extend for many miles, and confluent fans may eventually cover and fill relatively large intermontane basins. (R.M.F.)

ALLUVIUM. A general term used to designate the sand, silt and mud deposited by a stream, along its banks or upon its **floodplain,** during periods of high water. The word is derived from the Latin *ad,* to; and *luo,* wash. When alluvium is relatively fine-textured and contains sufficient organic matter it forms **soil.** Some of the oldest and richest agricultural regions are the great **delta** areas, such as the Nile, Euphrates, etc. (E.S.C.S.)

ALMAGEST. This is the name assigned by the Arabs to the great treatise on science compiled by **Ptolemy** during the 2nd century. The very name Almagest, which is a hybrid combination of the Greek superlative (*μεγιστη*) with the Arabic article (al), indicates the importance of this work to the early astronomers.

The Almagest is a collection of treatises on a variety of scientific subjects. In it is to be found the complete exposition of the Ptolemaic system for the structure of the universe. Perhaps the best known section of the Almagest is that dealing with the stars and the **constellations.** This section was taken from the works of Hipparchus and incorporated in the Almagest by Ptolemy with some improvements and additions. In this catalogue we first find the brightnesses of the stars divided into six **magnitudes,** a system which has persisted down to modern times. The positions of the stars given in the Almagest have proved of some little value in determining the constants of **precession** and also the **proper motions** of the stars. (W.K.G.)

ALMANAC. For the work of every person engaged in astronomy, whether as an astronomer in an observatory, a navigator on a ship at sea, or in the air, or a suveyor in the field, tables of certain astronomical data are indispensable. Many, in fact most, of these tables change from year to year. Among such material may be listed: the positions of the **sun, moon,** and **planets** for every day in the year, accurate positions of **stars** to be used for determination of local **time,** tables for computing **precession,** nutation, **aberration,** etc. Such material is published in almanacs which are computed and published several years in advance so that ships going off on long voyages can have the data at hand when they leave port.

In addition to the ephemerides and data listed above, almanacs also contain descriptions of such phenomena as **eclipses** of the sun and moon, **occultations** of stars by the moon, eclipses and configurations of the **satellites** of **Jupiter,** etc.

At the present time the computation of the material for the ephemerides of the different governments is a cooperative plan. The nautical almanac offices of the United States, Great Britain, France, Germany, and Spain do a share of the work. An examination of the preface for the American Ephemeris and Nautical Almanac for any year will show how the work for that particular year was distributed. (W.K.G.)

ALMANDITE. **Garnet.**

ALMOND. *Prunus Amygdalus.* Rosaceae. A medium-sized tree with pale pink or white flowers, probably native in western Asia and northern Africa. The fruit, a drupe (see **Fruit**), has the seed or kernel enclosed within a reticulated endocarp (see **Fruit**).

There are two kinds of almonds, bitter and sweet. Bitter almonds, used for flavoring, contain a high percentage of **hydrocyanic acid.** The sweet almond yields almond oil, and is used as a dessert and for confections. Almonds are grown incidentally in Mediterranean Eu-

rope, and in this country extensively in California. (R.M.W.)

ALOË. Liliaceae. A large genus of plants characteristic of drier parts of Africa, especially the southern part. Because of their ornamental appearance, with stiff habit and spiny-margined leaves, many of them are grown in cultivation. The rather small yellow or red flowers are born in large masses. Many species yield from the crushed leaves a purgative juice, which is called aloes, and which has been used extensively by eastern people. (R.M.W.)

ALOPECIA. Baldness—abnormal or natural loss of hair. It may be partial or complete, transient or permanent. It may be the natural accompaniment of old age or an indication of a toxic process in certain diseases. It can affect all body hair. (R.S.M.)

ALPACA. Mammalia, Artiodactyla. A South American domestic animal of the **camel** family, probably derived from the wild species known as the **guanaco,** *Lama huanaco*. It is the source of a long wool of fine quality and its flesh is excellent. Alpacas are kept at high altitudes in Bolivia and Peru. (A.W.L.)

ALPHA PARTICLE. Among the so-called nuclear particles, the **proton** and the alpha particle enjoy the distinction of not only appearing upon the disintegration of atomic nuclei (whether they had individual existence within the undivided nucleus or not), but of serving, by themselves, as the nuclei of certain atoms. Just as the atom of ordinary **hydrogen** (H^1) has the proton for its nucleus, so the nucleus of the **helium** atom is identical with the alpha particle, first recognized as composing the alpha rays emitted by many radioactive substances (see **Radioactive Changes**).

The mass of the alpha particle is very close to $6\,644 \times 10^{-24}$ g., and it carries a positive charge whose magnitude is exactly twice the elementary (electronic) charge (see **Electron**). This latter point, coupled with the fact that the mass is approximately four times that of the proton, leads one to question whether the alpha particle is a fundamental entity or is, like other atomic nuclei, made up of simpler structural units.

When alpha particles are given very high speed, either in natural radioactive emission or by artificial means, they prove to be extraordinarily effective in producing ionization in gases. (L.D.W.)

ALPHERATZ. Alpheratz (α **Andromedae**) is a star which was formerly allotted to the **constellation** of **Pegasus** by the Arabs. It is situated at the northeast corner of the great square of Pegasus. In **astrology,** Alpheratz portends honor and riches to all born under its influence. The star is a **spectroscopic binary** with a period of approximately 100 days. (W.K.G.)

ALSTONITE. Bromlite.

ALTAIR. Altair (α **Aquilae**) forms with β and γ of the same **constellation** the well-known line of stars which is a conspicuous feature of the early autumn sky and is sometimes referred to as the shaft of Aquila. This star was ill-omened in **astrology,** portending danger from reptiles. (W.K.G.)

ALTAZIMUTH. The altazimuth is the earliest type of mounting for astronomical telescopes. It is an instrument so mounted that it may be rotated about a horizontal and a vertical axis (i.e., rotated in **altitude** and **azimuth**). Perhaps the most familiar altazimuth instrument is the ordinary surveyor's transit or theodolite.

The great advantage of this type of instrument is the ease with which it may be set up. If the instrument has been properly constructed, the horizontal and vertical axes will be strictly perpendicular to each other, and all that is necessary to adjust the instrument for use is to level the horizontal axis of the instrument for all azimuths.

The altazimuth instrument is used in the field for laying down azimuth lines and for determination of **latitude** and **longitude** by measuring altitudes of celestial objects. A few large, fixed altazimuth instruments are in use in observatories for accurate determination of **declinations** of stars but for this purpose the **meridian circle** is most commonly used.

For ordinary astronomical observing the altazimuth instrument is less convenient than the **equatorial** because of the fact that the diurnal motion of the celestial sphere is parallel to the equator rather than the horizon, with the result that the instrument has to be moved about both axes to follow the celestial objects. (W.K.G.)

ALTERNATING CURRENTS. Currents in which the electricity moves periodically back and forth. The usual types of generator are so constructed that the electromotive forces induced in the armature conductors are periodically reversed, and unless the machine is provided with a commutator or other type of **rectifier,** this alternating voltage will be impressed upon the external circuit, giving rise to an alternating current. (See **Electric Currents** and **Electric Circuits.**)

The electromotive force may be represented by an equation of the type

$$E = E_0 \cos 2\pi nt, \tag{1}$$

in which E_0 is the maximum value of the e.m.f. ($t = 0$) and n is the frequency. (Some writers use the sine instead of the cosine in Eq. (1).) The resulting current follows a similar law, though it is in general out of phase with the e.m.f.

When a harmonic voltage such as that represented by Eq. (1) is impressed upon a circuit, the current is in general not derivable from the e.m.f. by a simple application of **Ohm's law**, but depends upon several factors. In the general case, account must be taken not only of the resistance R (ohms) of the circuit, but also of its **inductance** L (henrys), and its **capacitance** C (farads). (The circuit may include a series condenser, or may have enough **distributed capacitance** to have similar effect.) The current at any instant t in a series circuit is then given by the equation

$$I = \frac{E_0}{\sqrt{R^2 + \left(2\pi nL - \dfrac{1}{2\pi nC}\right)^2}} \cos (2\pi nt - \phi). \tag{2}$$

Here ϕ is the "phase angle," the angular amount by which the phase of the e.m.f. exceeds that of the current. Its value is given by

$$\tan \phi = \frac{4\pi^2 n^2 LC - 1}{2\pi nRC}. \tag{3}$$

ϕ reduces to zero if $L = 0$ and C is infinite (a non-inductive, no-condenser circuit), or if the circuit and the frequency are so adjusted that $C = \frac{1}{4}\pi^2 n^2 L$; in which latter case the circuit is in **resonance** with the e.m.f. (as is a tuned radio circuit). Under either of these conditions also, the current is related to the e.m.f. by Ohm's law, that is, $I = E/R$. Large inductances tend to make ϕ positive (current lags behind voltage); small capacitances tend to make it negative.

The radical in Eq. (2), which takes the place of R in Ohm's law and which equals R in the case of a resonant or a non-inductive, no-condenser circuit, is called the impedance of the circuit, while the parenthesis containing L and C represents the reactance.

The currents in circuits having other than simple series arrangement of resistances, inductances, and capacitances are given by appropriate formulas depending upon the arrangement and derived from the laws of networks. (See **Kirchhoff's Laws.**)

Since the power at any instant in a circuit of resistance R is E^2/R, the average power over a complete period is proportional to the average value of E^2. This may be denoted by $E_v{}^2$, in which E_v is the effective or virtual e.m.f., equal to $E_0/\sqrt{2} = 0.707\ E_0$ and to 1.11 times the average e.m.f. Similar relations hold for effective, average, and maximum current. The average power is not in general the product of the effective voltage and the effective current, $\frac{1}{2}E_0I_0$ (the apparent power), as it would be in a non-reactive circuit, but is equal to

$$P = \tfrac{1}{2}E_0I_0 \cos \phi, \qquad (4)$$

in which $\cos \phi$ is called the "power factor." The actual power is given by Eq. (4) in **watts**, as usual, while the apparent power is rated in "volt amperes" (effective volts $\times$ effective amperes). Many principles of ordinary alternating currents apply also to radio circuits of moderate frequency. (See **Radio Commuication.**) See also **Polyphase Currents** and **Transients.** (L.D.W.)

ALTERNATING-CURRENT CIRCUITS. The alternating-current circuit is that type of circuit which carries electrical current which rapidly reverses its direction of flow. A circuit is any series of electrical connections which give a continuous path through the various component parts and back to the starting point. Most electrical circuits are now a.c., although at first d.c. was a formidable contender. A.c. has received great impetus because of the simple way in which it can be changed in voltage by a **transformer.** This is a great advantage in transmitting electrical energy over long distances, since the cost of the line decreases and the efficiency increases for a given power transmission when the voltage is increased. The advantages of the **induction motor** are also a point in favor of a.c. It is not, however, without defect since its use brings into prominence **inductance** and **capacitance,** factors which appear in d-c calculations only during switching and are usually of no importance in **direct-current circuits.**

The essence of a-c voltage can be simply pictured by a curve showing the relation of the voltage value to time. Such a curve is shown in Fig. 1*a*. The points on the curve above the time axis represent the voltage in one direction across the circuit and those below the line the voltage in the other direction. An ideal a-c generator would produce an output which would be represented by Fig. 1*a*; but **harmonics** are frequently present and modify the wave form of the output. Fig. 1*b* shows, for a

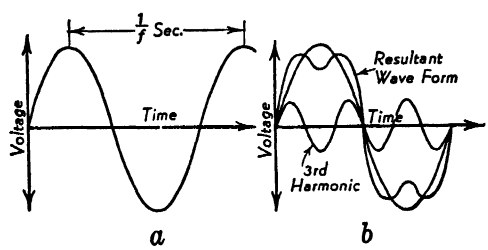


Fig. 1. A-c wave forms.

much exaggerated value, the effect on the wave of the third harmonic. The current would be distorted in a similar manner, the exact amount, however, depending on the amount of **reactance** in the circuit.

Since the value of the a.c. is continually changing it is necessary to define some sort of average value to use in calculations, measurements, etc. The unit is the ampere and the effective value of an a.c. is defined so that the same number of amperes of d.c. would produce the same heating effect in a resistance. This effective value is called the ***r.m.s.* (root mean square)** value and for a pure sine wave of current is the maximum value divided by $\sqrt{2}$. Voltage is similarly measured in r.m.s. volts (maximum value divided by $\sqrt{2}$). Unless otherwise specified a-c and voltage values are always given in these r.m.s. quantities. The frequency (f) of an a.c. is the number of complete cycles per second (see Fig. 1*a*).

The sine wave of Fig. 1*a* could be formed by plotting against time the projection upon a vertical axis of the end of a vector rotating at $2\pi f$ radians per sec. Since any sine wave can be obtained in this manner it is customary to represent the a-c and voltage waves by the vectors which would be used to get the plot. This greatly simplifies the calculations involving the alternating quantities. In a purely resistive circuit the current and voltage are in phase, that is, the peaks of the current occur simultaneously with those of the voltage. The vectors representing these would coincide in direction as shown in Fig. 2. The current lags the voltage in time sequence if the circuit has a net inductive reactance and leads if the net reactance is capacitive. This means that peaks of the current wave would occur after or before those of the voltage. These would be represented by drawing the vectors for current and voltage displaced as shown in Fig. 2. The angle θ is the angle

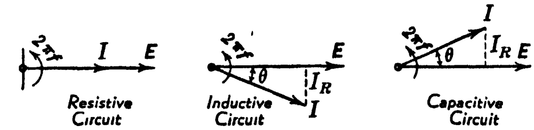

Fig. 2. Voltage-current relations in a-c circuits.

lag or lead and is called the power factor angle. The component of the current which is actually in phase with the voltage multiplied by the voltage gives the **power,** while the component 90° to the voltage gives the "wattless" or reactive power. It is the first of these which gives the useful work. It will be noted that the smaller the angle θ the less the reactive and the more the active power. It will also be noted that inductance and capacitance displace the current in opposite directions so by proper proportioning of them in certain circuits their effects will cancel. Electrical power is always the voltage times the current component in phase with it. As seen in Fig. 2 this current component is $I \cos \theta$, and hence the power is $EI \cos \theta$ where E and I are expressed in r.m.s. volts and amperes. The $\cos \theta$ is an important quantity in a-c circuits and is called the power factor.

Series and parallel arrangements of a-c circuits are more difficult to solve than those of d-c circuits as they usually contain inductance and capacitance, necessitating the use of reactance as well as resistance in obtaining the electrical characteristics of the circuit. The basic equations and quantities for the solution of a-c series and parallel circuits are given below:

$$E = IZ$$

For a series circuit:

$$Z = \sqrt{R^2 + X^2}$$
$$X = X_1 + X_2 + X_3 \cdots$$
$$R = R_1 + R_2 + R_3 \cdots$$

where X_1, X_2, etc., are $2\pi fL$ for the inductive reactance and $-\dfrac{1}{2\pi fC}$ for capacitive reactance, L being the inductance in henries and C the capacitance in farads; Z is the **impedance** and R is the **resistance.**

For a parallel circuit:

$$Z = \frac{1}{Y_0}$$

where Y_0 is the total **admittance.**

While a.c. supplied to small consumers is usually single-phase, ***alternators*** are commonly wound for 3 phases. Sometimes 2 or 4 phases are used for distribution, and frequently 6, 12 or more phases are obtained by special transformer connections for supplying **rectifiers.** The

single-phase circuit is obtained from a polyphase one by using only one phase of the system. Polyphase power has certain advantages over a single phase:

1. Transmission is more economical.
2. Equipment is smaller, less complicated and generally more efficient.
3. Power fluctuations are less. This is analogous to the difference between a single-cylinder and multi-cylinder automobile engine.

Three-phase is the most common system in use. The power is $\sqrt{3}$ times the power of a single-phase circuit having the same line voltage and current. (F.T.M., L.R.Q.)

ALTERNATING-CURRENT MOTOR. **Motors.**

ALTERNATION OF GENERATIONS. In the life history of many **Thallophytes** and of all plants in the divisions above the Thallophytes, there are two distinct phases in the life cycle which regularly alternate. In the **algae,** the alternating individuals are frequently indistinguishable until fruiting occurs, when it becomes apparent that one plant produces asexual **zoospores** which grow directly to form new plants, while the other plant (of the alternate generation) produces **gametes,** or sexual **cells.** These gametes fuse in pairs before growing to form new plants. Since two cells, and also their nuclei, fuse, it is obvious that there is a doubling of the nuclear substance. The plant having this double nuclear nature is called diploid, while the other generation is called haploid. In a mature diploid plant, there occurs at the time of spore formation a special type of division, **meiosis,** or reduction division, in which the double nuclear condition is reduced. While many algae have the two generations of similar appearance, others, notably the brown algae known as kelps, show a striking dissimilarity. The asexual plants are the familiar large brown seaweeds so frequently cast up on our coasts, while the sexual plants are minute and rarely seen. In kelps, and many other plants, these sexual plants are of two sorts, one, the male, producing minute biciliate sperms, the other, the female, forming oögonia with which the sperms unite. The alternate generations in the higher plants are separately described under each division (**Bryophytes, Pteridophytes,** and **Spermatophytes**). Among animals, alternation of generations is well marked in the **hydrozoan coelenterates,** where the **polyp** of many species is an asexual form capable only of securing nourishment, defending the colony, and producing new individuals by budding or some similar asexual process. The **medusa** is a sexual form produced in this manner. It gives rise to **germ cells** and through its sexual reproduction new individuals are formed which constitute another asexual generation. (R.M.W., A.W.L.)

ALTERNATOR. An electromotive force is generated in a conductor when it is moved so as to cut the lines of force between the poles of a magnet. The elementary principle of a simple two-pole, single-phase alternator is shown in Fig. 1. When the magnet revolves it will

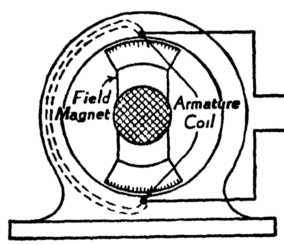

Fig. 1. Elementary alternator.

carry with it lines of force which will cut the conductor, which is a wire loop embedded in the stationary portion called the armature, and will generate a.c.

This elementary principle must be expanded in several directions if a practical generator of a.c. is to be had. First, the rotating part, or rotor, must have magnetic strength in excess of that which could be obtained from a simple permanent magnet. In other words, the poles must be formed by electromagnets whose excitation, in the form of d.c., must be carried to the rotor through slip-ring connections. The rotor is called the field, and the current it uses is called the field current. In high-speed steam turbine-driven alternators as few as two poles are often used, while in slow-speed water-turbine units the number is frequently nearly 100. The stationary part, called the stator, or armature, usually has three sets of overlapping coils, connected in three separate circuits. These three circuits, or phases, are usually connected in one or the other ways shown in Fig. 2.

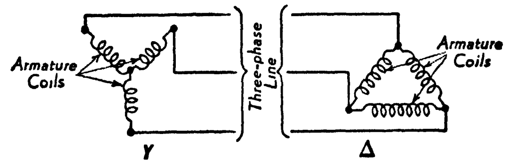

Fig. 2. Comparison of Y and Δ connections of three-phase alternator windings.

The *Y* connection is preferred because of the usefulness of the neutral point, and the fact that the line voltage is $\sqrt{3}$ times the phase voltage, whereas it is only equal to the phase voltage in Δ connection. The neutral point is connected to the fourth wire of a four-wire, three-phase system, and left unconnected, or grounded, in the three-wire system. Several advantages are realized by making the rotating part the **field,** and the stationary part the **armature.** The a.c. may be generated at very high voltages because it is not necessary to connect it through movable contacts as would be the case if the armature revolved. It is not necessary to conduct high-load currents through slip rings and **brushes** if the armature is fixed. The armature conductors can be very rigidly braced in position, and may be much better disposed than if they were required to be in the rotor.

Engine and hydraulic turbine-driven alternators are in the slow-speed class, and are characterized by large diameter, short length, and many poles. The steam turbine-driven alternator is a high-speed machine having a length larger than its diameter. Standard speeds of turbine-driven alternators range from 1200 to 3600 rpm, with 1800 rpm very common practice.

Basically, the alternator is a device for converting mechanical into electrical energy. While it is able to do this with a high degree of efficiency, it does suffer the following losses:

1. Friction and windage from bearings, brushes, and fan action of the rotor.
2. Core loss, which is the result of **eddy currents** and **hysteresis** in the iron core.
3. Resistance heating loss in the armature and field conductors.
4. Resistance loss of the field **rheostat.**
5. Exciter loss.
6. Ventilation loss.

Practically all generator losses appear as heat in and about the windings, and to maintain these at a safe working temperature, a cooling medium must be employed. Air has been the medium generally used. The rotor may or may not be able to produce its own fan action, depending on the size, speed, and construction of the rotor. Ventilating air frequently has to be brought through a duct and discharged through the alternator. Hydrogen is rapidly becoming a common cooling medium as it is much more effective and produces less windage loss. For its use the generator must be totally enclosed and gas-tight. To supply the d.c. for the field, a source of d.c. at 110–250 volts is necessary. This is delivered from a small d-c generator called the exciter. The exciter may be driven from an extension of the alternator

shaft, or it may be driven by some independent means, such as motor or engine.

When alternators are operated in **parallel**, the division of load between them is not accomplished by changing the generated voltage, as in d-c generators, but by changing power input from the prime mover through the adjustment of the engine or turbine **governor.** Before being paralleled, two alternators must have the same phase sequence and frequency. Their voltages must be equal, and in phase; that is, with the peaks of wave forms coincident in time and direction. (F.T.M.)

ALTIMETER. An instrument used by aviators to determine the height of the plane above sea level is known as an altimeter. The most commonly used type of altimeter is, in reality, a sensitive **aneroid barometer** with the dial calibrated to read altitude above sea level when, and only when, the earth's atmosphere is in "standard conditions." An observer sitting in a plane resting on the ground at an airport located 1500′ above sea level might set his altimeter to read 1500′. If, while sitting in the plane the air temperature should rise, the observer would find that the altimeter indicated a rise of the plane; if the barometric pressure should fall, the altimeter would again indicate a rise of the plane.

On most altimeters there are at least two adjustments which must be made before take-off, and then checked constantly while in flight. The first is a so-called "altimeter setting" which corrects for the difference between the actual barometric pressure (reduced to sea level at standard temperature for the region in which the plane is operating) and the "standard barometric pressure" for the altitude of that region. Before take-off the aviator obtains the local barometric pressure, reduced to sea level and standard temperature, sets this figure on a scale visible on the face of the altimeter. He now makes the second adjustment by rotating the dial of his instrument until the indicator points to the altitude of the airport. As he climbs, the altimeter will register the so-called "pressure altitude" above sea level. This pressure altitude will be his actual altitude if, and only if, the decrease of temperature with altitude is that of the normal **lapse rate.** To obtain the actual altitude in case the lapse-rate temperature is not normal, involves a computation by means of an equation containing the observed pressure altitude and the actual temperature gradient from the ground. This computation may be made with an accuracy sufficient for most purposes by means of a scale and slide provided on most **navigational computers.** If the aviator now proceeds cross-country, the reading of the altimeter will give the pressure altitude if, and only if, the barometric pressure, reduced to sea level and standard temperature at the ground immediately below him, is the same as that at the locality where the first altimeter setting was made. The Weather Bureau and other agencies provide facilities for reporting the barometric pressure, reduced to sea level at standard temperature, at numerous stations. A careful aviator will obtain this altimeter setting at frequent intervals during a flight and alter the reading of the altimeter-setting scale of his own instrument whenever necessary. It should be remembered that the pressure-type altimeter gives the altitude above sea level after proper correction, not the altitude of the plane above the ground immediately below it. (See **Altitude; Instruments, Aviation.**) (W.K.G.)

ALTITUDE. The term altitude is used as synonymous for height, or distance above the surface of the earth. The **altimeter** is used in aviation to measure the altitude of a plane.

In astronomy and **navigation** the altitude of a celestial object is that coordinate in the **horizontal system** of spherical coordinates that is measured in the plane of the vertical circle through the object from the **horizon** to the object. Altitude is probably the most frequently measured of all celestial coordinates since it is universally used in **celestial navigation** to find **lines of position** for the determination of the location of a ship at sea, or a plane in the air. Altitude is also measured by geodetic surveyors for accurate determination of **latitude** and is used by astronomers for determination of the **declinations** of the stars.

At fixed stations, such as those established by the Coast and Geodetic Survey, an **altazimuth** instrument is used for measuring altitude. Navigators use the **sextant** for measuring altitude.

All observations for altitude must be corrected for atmospheric **refraction** and for **parallax.** Altitudes measured with the portable instruments must have additional corrections applied as discussed in the article on the **sextant.** (W.K.G.)

ALTOCUMULUS. **Clouds.**

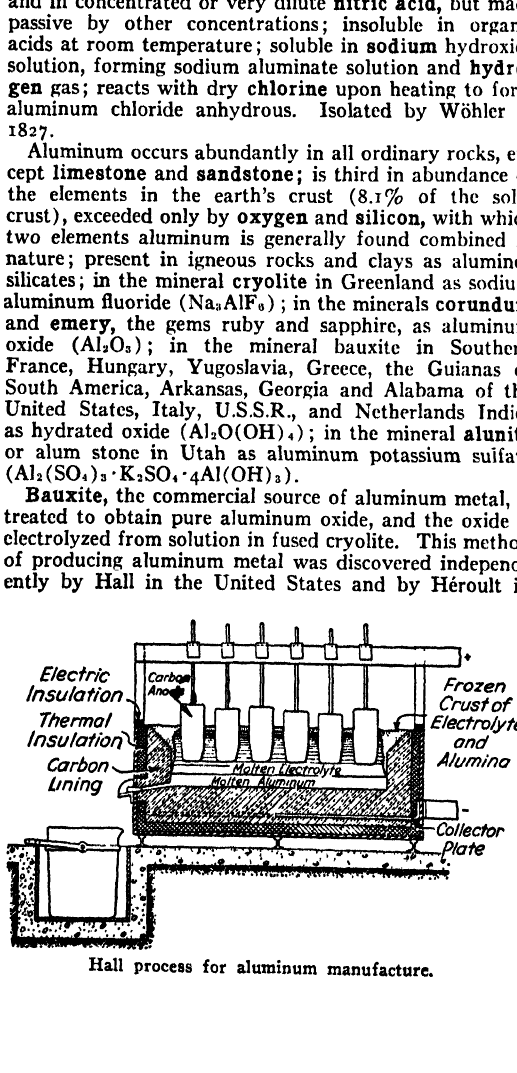
ALTOSTRATUS. **Clouds.**

ALUMINUM. Symbol: Al. Atomic number: 13. Atomic weight: 26.97. Density: 2.70. Hardness: 3. Melting point: 660° C. Boiling point: 1800° C. No isotope, but of single atomic form: 27.

Aluminum is a silver-white metal, with a bluish tinge, capable of taking a high polish, ductile and malleable; a thin, protective, transparent film of oxide is formed upon exposure to air; upon heating to 580° C. in **oxygen,** burns with intense heat and light; soluble in **hydrochloric acid, in sulfuric acid** (of strength above 10%), and in concentrated or very dilute **nitric acid,** but made passive by other concentrations; insoluble in organic acids at room temperature; soluble in **sodium** hydroxide solution, forming sodium aluminate solution and **hydrogen** gas; reacts with dry **chlorine** upon heating to form aluminum chloride anhydrous. Isolated by Wöhler in 1827.

Aluminum occurs abundantly in all ordinary rocks, except **limestone** and **sandstone;** is third in abundance of the elements in the earth's crust (8.1% of the solid crust), exceeded only by **oxygen** and **silicon,** with which two elements aluminum is generally found combined in nature; present in igneous rocks and clays as alumino-silicates; in the mineral **cryolite** in Greenland as sodium aluminum fluoride (Na_3AlF_6); in the minerals **corundum** and **emery,** the gems ruby and sapphire, as aluminum oxide (Al_2O_3); in the mineral bauxite in Southern France, Hungary, Yugoslavia, Greece, the Guianas of South America, Arkansas, Georgia and Alabama of the United States, Italy, U.S.S.R., and Netherlands Indies as hydrated oxide ($Al_2O(OH)_4$); in the mineral **alunite** or alum stone in Utah as aluminum potassium sulfate ($Al_2(SO_4)_3 \cdot K_2SO_4 \cdot 4Al(OH)_3$).

Bauxite, the commercial source of aluminum metal, is treated to obtain pure aluminum oxide, and the oxide is electrolyzed from solution in fused cryolite. This method of producing aluminum metal was discovered independently by Hall in the United States and by Héroult in



Hall process for aluminum manufacture.

France in 1886, and has been the sole method since that time. In present-day production and consumption of metals, aluminum stands fifth, and has shown a quantity increase in recent years greater than any other metal.

WORLD PRODUCTION

YEAR	SHORT TONS
1900	7,000
1910	48,000

Ratio of steel to aluminum	330 to 1	240 to 1

* Primary copper 72% of this
† Primary copper 66% of this
‡ Primary zinc 93% of this.

Aluminum is largely used in articles of commerce and technology (1) where there is demanded lightness and strength, e.g., airplane, automobile, rail car, either pure or in alloy with silicon and another metal such as magnesium, (2) as electrical **conductor**, in competition with copper, (3) due to ease of workability and resistance to wear and corrosion, as cooking utensils, large and small containers, chemical apparatus, (4) for the production of local, very high temperature, or reduction of difficulty reducible oxides, e.g., aluminum plus **iron** oxide to form aluminum oxide glass, plus iron, and for iron oxide there may be substituted many other oxides, to produce the metal corresponding to the oxide used, (5) for paint, when finely powdered, (6) as a protective coating on steel, (7) in alloys, principally with copper, silicon, magnesium, manganese, nickel, zinc (**Aluminum Alloys**).

Aluminum compounds are generally made starting with bauxite, which is reactive with acids and with bases. With acids, e.g., sulfuric acid, any iron contained in the bauxite is dissolved along with the aluminum and silicon is left in the residue, whereas with bases, e.g., sodium hydroxide, any silicon is dissolved and iron left in the residue.

Acetate: Aluminum acetate ($Al(C_2H_3O_2)_3$), white crystals, soluble, by reaction of aluminum hydroxide and **acetic acid** and then crystallizing. Used (1) as a mordant in dyeing and printing textiles, (2) in the manufacture of lakes, (3) for fireproofing fabrics, (4) for waterproofing cloth.

Alums: Aluminum potassium sulfate, "alum" ($K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$), white crystals, soluble, by crystallizing a solution of aluminum sulfate and **potassium** sulfate; other alums may be prepared, (1) by substituting for potassium sulfate, **sodium**, or **ammonium** sulfate, (2) by substituting for aluminum sulfate, **chromium** or **ferric** sulfate. The alums, therefore, are mixed salts of the type shown above, and do not necessarily contain aluminum; anhydrous aluminum potassium sulfate, "burnt alum" ($K_2SO_4 \cdot Al_2(SO_4)_3$), is made by heating alum until water is removed.

Aluminates: Sodium aluminate ($NaAlO_2$), white solid, soluble, (1) by reaction of aluminum hydroxide and sodium hydroxide solution, (2) by fusion of aluminum oxide and sodium carbonate; the solution of sodium aluminate is reactive with carbon dioxide to form aluminum hydroxide. Used as a mordant in the textile industry, in the manufacture of artificial zeolites, and in the hardening of building stones. See silicates below and **calcium** aluminates.

Alundum: See oxide (below).

Carbide: Aluminum carbide (Al_4C_3), yellowish-green solid, by reaction of aluminum oxide and **carbon** in the **electric furnace**, reacts with water to yield **methane** gas and aluminum hydroxide.

Chlorides: Aluminum chloride ($AlCl_3 \cdot 6H_2O$), white crystals, soluble, by reaction of aluminum hydroxide and **hydrochloric acid**, and then crystallizing; anhydrous aluminum chloride ($AlCl_3$), white powder, fumes in air, formed by reaction of dry aluminum oxide plus carbon heated with chlorine in a furnace, used as a reagent in **petroleum** refining and other organic reactions.

Fluoride: Aluminum fluoride (AlF_3), white solid, soluble, by reaction of aluminum hydroxide plus **hydrofluoric acid** and then crystallizing ($2AlF_3 \cdot 7H_2O$), used in glass and porcelain ware.

Hydroxide: Aluminum hydroxide ($Al(OH)_3$), white gelatinous precipitate, by reaction of soluble aluminum salt solution and an alkali hydroxide, carbonate or sulfide (sodium aluminate is formed with excess sodium hydroxide but no reaction with excess ammonium hydroxide), upon heating aluminum hydroxide the residue formed is aluminum oxide. Used as intermediate substance in transforming bauxite into pure aluminum oxide.

Nitrate: Aluminum nitrate ($Al(NO_3)_3$), white crystals, soluble, by reaction of aluminum hydroxide and **nitric acid**, and then crystallizing.

Oleate: Aluminum oleate ($Al(C_{18}H_{33}O_2)_3$), yellowish-white powder, by reaction of aluminum hydroxide, suspended in hot water, shaken with **oleic acid**, and then drying, the product is used (1) as a thickener for lubricating oils, (2) as a drier for paints and varnishes, (3) in waterproofing textiles, paper, leather.

Oxide: Aluminum oxide, alumina (Al_2O_3), white solid, insoluble, melting point 2020° C., formed by heating aluminum hydroxide to decomposition; when bauxite is fused in the electric furnace and then cooled there results a very hard glass ("alundum"), used as an abrasive (hardness 9 Mohs scale) and heat refractory material. Aluminum oxide is the only oxide which reacts both in water medium and at fusion temperature, to form salts with both acids and alkalis.

Palmitate: Aluminum palmitate ($Al(C_{16}H_{31}O_2)_3$), yellowish-white powder, by reaction of aluminum hydroxide, suspended in hot water, shaken with palmitic acid, and then drying, the product is used (1) as a thickener for lubricating oils, (2) as a drier for paints and varnishes, (3) in waterproofing textiles, paper, leather, (4) as a gloss for paper.

Silicates: Many complex aluminosilicates or silicoaluminates are found in nature. Of these, clay in more or less pure form, pure clay, kaolinite, kaolin, china clay ($H_4Si_2Al_2O_9$ or $Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$) is of great importance. Clay is formed by the weathering of igneous rocks, and is used in the manufacture of bricks, pottery, porcelain and Portland cement. (See **calcium aluminosilicates; Ceramics; Cement, Portland.**)

Stearate: Aluminum stearate ($Al(C_{18}H_{35}O_2)_3$), yellowish-white powder, by reaction of aluminum hydroxide suspended in hot water, shaken with **stearic acid**, and then drying the product, used (1) as a thickener for lubricating oils, (2) as a drier for paints and varnishes, (3) in waterproofing textiles, paper, leather, (4) as a gloss for paper.

Sulfate: Aluminum sulfate ($Al_2(SO_4)_3$), white solid,

soluble, by reaction of aluminum hydroxide and **sulfuric acid,** and then crystallizing, used (1) as a clarifying agent in water purification, (2) in baking powders, (3) as a mordant in dyeing, (4) in sizing paper, (5) as a precipitating agent in sewage disposal; aluminum potassium sulfate, see **alums** and **alunite.**

Sulfide: Aluminum sulfide (Al_2S_3), white to grayish-black solid, reactive with water to form aluminum hydroxide and **hydrogen sulfide,** formed by heating aluminum powder and sulfur to a high temperature.

Aluminum in solution of its salts is detected by the reaction (1) with ammonium salt of aurin tricarboxylic acid ("aluminon"), which yields a red precipitate persisting in ammonium hydroxide solution, (2) with alizarin red S, which yields a bright red precipitate persisting in acetic acid solution. (R.K.S.)

ALUMINUM ALLOYS. The aluminum alloys, like those of other commercial metals, can be divided into two broad classes: (1) wrought alloys and (2) casting alloys. The wrought-alloy products include sheet, plate, foil, tubing, rods, bars, wire, structural and special shapes, rivets, forgings, screw machine products, paste and powder for paint, and impact extrusions, and the casting-alloy products comprise sand castings, permanent mold castings and die castings. Some wrought alloys are available in practically all of the commercial products while others are special-purpose alloys and may be available in but one or two products. Similarly, some casting alloys are used only for one or two of the three usual types of castings.

Aluminum of commercial purity (99% minimum aluminum) is widely used for making wrought products but finds rather limited use in castings. In wrought forms it has a tensile strength of about 13,000 lbs. per sq. in. when in the annealed temper and of about 24,000 lbs. per sq. in. when in the cold-rolled hard temper. It is particularly useful in the food and chemical industries, where its resistance to corrosion and high thermal conductivity are desirable characteristics, and in the electrical industry, where its electrical conductivity of about 60% of that of copper and its light weight make it desirable for wire, cable and bus bars. Large quantities also are used for foil, to be used in packaging food products, for paste and powder to be used in paint and for collapsible tubes.

The addition of alloying elements to the commercially pure metal results in an increase in the strength and usually also has some effect on the other characteristics. Additions of silicon, for example, considerably improve the casting characteristics. The metals commonly used for alloying with aluminum are copper, magnesium, silicon, manganese, zinc, nickel, chromium, titanium and iron. Although they may be used singly, they more often are used in combination and, by properly selecting the combinations and amounts, may result in an alloy which can be heat treated to produce a tensile strength as high as 88,000–90,000 lbs. per sq. in. As with most other metals, the strength of any aluminum alloy can be increased by cold working but, if the alloy is heat-treatable, the strength usually can be increased much more by heat treatment than by cold working.

The first three wrought alloys in the accompanying table are not heat-treatable, but are given increased strength by cold mechanical deformation. These alloys are usually classified as annealed, quarter hard, half hard, three-quarters hard and hard, depending on the amount of cold work done. Tensile strength increases with the hardness and ductility decreases. The range of mechanical properties is from 16,000 lbs. per sq. in. tensile strength with 30% elongation up to 41,000 lbs. per sq. in. with 7% elongation, depending on the alloy composition and the extent of deformation. A very important group of alloys is that in which the mechanical properties are greatly improved by thermal treatments. A typical example of an alloy in this group is Duralumin, devel-

oped by Wilm just before World War I. The alloy contained 4% copper, 0.5% magnesium and 0.5% manganese. After casting and rolling to sheet, the material was heated at 500° C. (932° F.), quenched in cold water and allowed to stand (age) for about 60 hours. This treatment increased the tensile strength to about 62,000 lbs. per sq. in. with an elongation of about 20%. A variety of alloys susceptible to heat treatment has since been developed. Differences in composition require different temperatures for the high-temperature heating known as solution treatment and differences both in time and temperature of aging. In some cases normal or room-temperature aging is sufficient, but in others a somewhat higher temperature (artificial aging) is necessary as the final operation. Tensile strengths vary in this group from about 40,000 lbs. per sq. in. to about 88,000 lbs. per sq. in. or even higher with elongations from 10 to 27%. Wrought alloys taken at the correct time in the treating cycle can be rolled, forged, drawn, stamped, extruded or spun.

Prior to about 1920, heat-treatable aluminum casting alloys were unknown and most castings were made from an alloy containing about 8% copper and known commercially as No. 12. This alloy, modified by the addition of silicon and iron, with or without zinc, is still used for many low-cost, general-purpose castings. As cast test bars have a tensile strength of about 24,000 lbs. per sq. in. when cast in sand and of about 29,000 lbs. per sq. in. when cast in permanent molds and an elongation of about 1.5%. Other alloys commonly used in the as-cast condition include the 5% and 12% silicon alloys, the latter chiefly for die castings, the 4% and 8% magnesium alloys and several alloys containing about 3–5% copper and about 4–8% silicon. Test bars of these alloys have a tensile strength of about 19,000–25,000 lbs. per sq. in. when cast in sand and of about 24,000–28,000 lbs. per sq. in. when cast in permanent molds. The elongation varies from about 2–9%. Die-cast test bars of alloys of this type have tensile strengths of 30,000–45,000 lbs. per sq. in. and elongations of about 2–7%. Several alloys containing zinc or zinc and magnesium, together with small amounts of several other elements, have attained some commercial importance in recent years and, in the as-cast condition, develop a tensile strength of 30,000–35,000 lbs. per sq. in. with an elongation of about 4–5%.

The more important heat-treatable casting alloys used for structural applications are the 4%-copper and the 10%-magnesium alloys and several alloys containing about 5–8% silicon with or without about 1–2% copper and small additions of magnesium. Test bars of these alloys, depending on the heat treatment used, develop tensile strengths of 25,000–46,000 lbs. per sq. in. and elongations of 1.5–14%. Several of the commercial heat-treatable alloys are particularly intended for use at elevated temperatures such as are encountered by the pistons and cylinder heads of an internal combustion engine. The oldest of these is an alloy containing 10% copper, about 1% iron and 0.2% magnesium. Another, often referred to as "Y Alloy," contains 4% copper, 2% nickel and 1.5% magnesium and a third contains 12% silicon, 2.5% nickel, 1% magnesium and 0.8% each copper and iron. A variety of heat treatments are used for these alloys in order to obtain specific characteristics, with the result that the tensile strength may vary from about 27,000 to 47,000 lbs. per sq. in. The typical properties of a number of casting alloys are shown in the accompanying table.

NOMINAL CHEMICAL COMPOSITION[1] AND TYPICAL PROPERTIES OF SOME ALUMINUM CASTING ALLOYS

In general, the alloys containing substantial amounts of silicon have the best foundry characteristics and a high resistance to corrosion, but they are not as easily machined as the alloys in which copper is the principal alloying element. The aluminum-magnesium alloys also have a high resistance to corrosion, can be machined with relative ease and will develop high strengths, but they require special foundry practices if the magnesium content exceeds about 4%. The aluminum-copper alloys, particularly if they also contain about 1% or more silicon, have good foundry characteristics, can be machined with relative ease and have a good resistance to corrosion, although they should be given paint protection if exposed to marine or severely-corrosive industrial atmospheres.

Aluminum alloys may be joined by any of the conventional welding methods, gas torch, electric spot welding and, for some applications, arc welding. Parts subject to heavy stresses are usually jointed by riveting since the heat of welding will destroy, to some extent, the beneficial effects of heat treatment. The physical characteristics of aluminum alloys, essentially their high electrical and thermal conductivity, their low melting points, and ease of oxidation make the welding techniques differ considerably from those for steel and require experience for successful operation. Brazing with aluminum-rich alloys produces excellent joints with some alloys. Soldering is rarely used and only when the joint can be provided with adequate protection against corrosion.

Most aluminum alloys are highly resistant to atmospheric attack. Under some conditions, as for example when the alloy is in continued contact with salt water, or under other corrosive conditions, some protection

must be given. Some of the alloys are protected by cladding with a surface layer of pure aluminum or an alloy which is electronegative to the strong alloy core; these are known as alclad alloys and exhibit unusual resistance to attack. A protective coating can be applied by electrolytic oxidation (anodizing) which applies a thick protective oxide coating to the aluminum alloy. Under many conditions of service, the alloy may be protected by the use of paint, lacquer or enamel over the anodized surface or on the bare surface.

The principal applications of aluminum and its alloys are in the transportation industry—automobiles, buses and trucks, aircraft, railway cars and ships. Other large tonnages are used for metal products, electric conductors, cooking utensils, architectural uses, machinery and equipment for the chemical industries. (R. S. WILLIAMS, M.I.T.)

ALUMINUM BRONZES. Brass and Bronze.

ALUMS. These are double salts having the general formula $M_2SO_4X_2(SO_4)_3 24H_2O$. M is any univalent **cation** and X any trivalent **cation,** e.g., sodium alum, ammonium alum, chrome alum. (See **Aluminum.**) (R.K.S.)

ALUNITE or **ALUMSTONE.** The mineral alunite is a basic hydrous **sulfate** of **aluminum** and **potassium;** a variety called natroalunite is rich in **soda.** Alunite crystallizes in the **hexagonal** system and forms rhombohedrons with small angles, hence resembling cubes. It may be in fibrous or tabular forms, or massive. Hardness, 3.5–4; specific gravity, 2.58–2.75; luster, vitreous to pearly; streak white; transparent to opaque; brittle; color, white to grayish or reddish.

Alunite is commonly associated with acid **lavas** due to the sulfuric vapors often present; it may occur around **fumaroles** or associated with **sulfide** ore bodies. It has been used as a source of potash. It is found in Czechoslovakia, Italy, France, and Mexico. In the United States alunite is found in Colorado, Nevada, and Utah. (E.S.C.S.)

ALVEOLUS. 1. A minute sac-like chamber in a hollow organ, such as the air sacs of the lungs and the components of various glands. Its sac-like form distinguishes it from other chambers in which the walls are relatively thicker. 2. The cavity in the jaw in which the root of a tooth is fixed. (A.W.L.)

AMALGAM. An amalgam is an **alloy** of **mercury** with another metal. Usually amalgams are prepared by man, but there is a rare mineral, called amalgam, which is probably a mutual solid solution of silver and mercury, as the percentages of each vary to some extent. It crystallizes in the **isometric** system; hardness, 3–3.5; specific gravity, 13.75–14.1; luster, metallic; color, silver-white; streak the same, opaque.

Occurs in Bavaria, Czechoslovakia, France, Spain, Norway, Chile, and British Columbia. (E.S.C.S.)

AMANITA. Agarics.

AMARANTHS. A group of plants, including many coarse and obnoxious pigweeds. *Amarantus caudatus,* the familiar Love-lies-bleeding, and *A. hypochondriacus,* the Princess feather, are more attractive, widely planted garden annuals. (R.M.W.)

AMAZONITE. Feldspar.

AMAZONSTONE. Feldspar.

AMBER. Amber is a **fossil resin** which has been known since early times because of its property of acquiring an **electric charge** when rubbed. In modern times it has been used largely in the making of beads, cigarette holders, and trinkets. Its amorphous non-brittle nature permits it to be carved easily and to acquire a very smooth and attractive surface. Amber is soluble in various organic solvents, such as ethyl alcohol and ethyl ether.

It occurs in irregular masses showing a **conchoidal** fracture. Hardness, 2.25; specific gravity, 1.09; luster, resinous; color, yellow to reddish or brownish; it may be cloudy. Some varieties will exhibit **fluorescence.** Amber is transparent to translucent, melts between 250° and 300° C.

Amber has been obtained for over 2000 years from the **lignite**-bearing Tertiary **sandstones** on the coast of the Baltic Sea from Danzig to Memel, also Denmark, Sweden and the other Baltic countries. Sicily furnishes a brownish-red amber that is fluorescent.

The association of amber with **lignite** or other fossil woods as well as the beautifully preserved insects that are occasionally in it is ample proof of its organic origin. (E.S.C.S., R.M.W.)

AMBERGRIS. A fragrant waxy substance formed in the intestine of the sperm whale and sometimes found floating in the sea. It is used in the manufacture of **perfumes** to increase the persistence of the scent. (A.W.L.)

AMBLYGONITE. A rather rare compound of **fluorine, lithium, aluminum** and **phosphorus.** It crystallizes in the **triclinic** system; hardness 6; specific gravity 3.01–3.09; luster vitreous to greasy or pearly; color white to greenish, bluish, yellowish or greyish; streak white; translucent to sub-transparent.

Amblygonite occurs in **pegmatite** dikes and veins associated with other lithium minerals, is used as a source of lithium salts. Its name is derived from two Greek words meaning blunt and angle in reference to its cleavage angle of 75° 30′.

It is found in Saxony, France and Australia; and in the United States at Hebron, Paris, Greenwood, Rumford and Auburn, Maine; Branchville, Connecticut; Black Hills, South Dakota; and Pala, California. (E.S.C.S.)

AMBLYOPIA. Impairment of vision without organic disease of the eye proper. It may be due to **alcohols**—especially **methyl alcohol,** or various chemicals such as **arsenic** or **quinine,** etc. It may also occur in various diseases such as **nephritis** or **uremia** from any cause. It may also indicate certain diseases of the optic nerve or of the brain. (D.M.H.)

AMBLYPODS. Paleocene.

AMBULACRAL FEET. Tube Feet.

AMBULACRAL GROOVE. The groove along the lower or oral surface of the arm of a starfish, in which the tube feet are located. (A.W.L.)

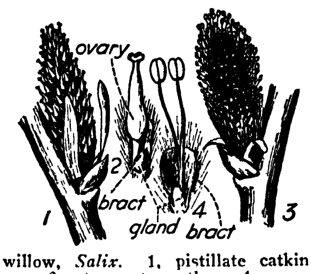
AMBUSH BUG. Insecta, Hemiptera. Predacious **bugs** named from their habit of lying in wait for their prey in flowers where their colors conceal them. The most common species is *Phymata erosa.* (A.W.L.)

AMEIVA. Reptilia, Sauria. A **lizard** of Central and South America. The name is that of the genus, applied as a common name to the score of included species. (A.W.L.)

AMENORRHEA. Menstruation.

AMENT, or **CATKIN.** An inflorescence composed of many flowers, aggregated into long, often tassel-like

masses. The perianth (see **Flower**) is completely lacking, or may be present in a scale-like form. The flowers of willows (pussy-willows), poplars, alders, beeches, oaks



Flowers of willow, *Salix*. 1, pistillate catkin; 2, a single pistillate flower, 3, staminate catkin; 4, a single staminate flower.

and birches are familiar examples. Most of them are wind-pollinated flowers. (R.M.W.)

AMERICAN MONKEY. Mammalia, Primates. Any **monkey** of the family Cebidae, restricted to the New World. They differ from the apes and monkeys of the Old World in the broader nose and have sometimes been included with the marmosets in a group Platyrhini, based on this character. (A.W.L.)

AMERICAN STANDARD. Screw Thread.

AMERICIUM. Chemical Composition, I. Elements.

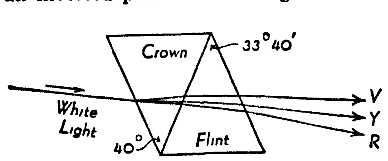
AMETHYST. Amethyst is purple- or violet-colored **quartz,** believed to be due to the admixture of a small amount of a **manganese** compound. Its physical characters are the same as quartz. An old superstition is that if worn as a gem it would cure intemperance. Oriental amethysts are purple **corundum.**

Amethysts are found at many localities, the Ural Mountains, India, Ceylon, Madagascar, Uruguay, Brazil, the Thunder Bay district of Lake Superior in Ontario, and Nova Scotia. In the United States amethysts are found in Michigan, Virginia, North Carolina, Montana and Maine.

The name amethyst is generally supposed to have been derived from the Greek word meaning not drunken. Pliny suggested that the term was applied because the amethyst approaches but is not quite the equivalent of a wine color. (E.S.C.S.)

AMICI PRISM. A direct-vision **prism,** that is, a prism combination by which a beam of light is dispersed into a spectrum without mean deviation Such prisms are sometimes used in direct-vision **spectroscopes.**

The principle will be clear from the following example. Assume an inverted prism of crown glass with an angle



The deviation due to the crown glass prism is neutralized by that of the flint glass prism, for the middle of this spectrum (yellow) only.

of 40°, used with an erect prism of flint glass. Yellow sodium light (5893 A.) is deviated by the crown-glass prism through +22° 32′ (upward). For the flint-glass prism to produce an equal negative (downward) deviation it must have an angle of 33° 40′. (Each prism is supposedly set for minimum deviation.) Together they produce no deviation for this wavelength. But if light of 7682 A. (red) is used, the deviation of the crown glass is +22° 16′, while that of the flint is −22° 10′, giving a net deviation of +6′. And for the wavelength 4047 A. (violet), the deviations are, respectively, +23° 12′ and −23° 44′, giving −32′. There is thus, between the ends of the visible spectrum, a separation of 38′. Additional pairs of prisms may be used to increase the dispersion. (L.D.W.)

AMIDES. Amines and Amides.

AMIDOL. A developer used in photography. It is 2–4 diamino **phenol.** (R.K.S.)

AMIDOPYRINE. The chemical name for "pyramidon," often used as an **antipyretic** and to relieve pain—particularly of **joint** inflammations, headaches and in colds. In certain individuals who are sensitive to the **drug,** it diminishes the number of white **blood** cells, and leads to **agranulocytosis.** (R.S.M., D.M.H.)

AMINATION. Amination is the term used here to cover the processes of introducing the amino group (—NH_2) into organic compounds of the **amine** type. The principal methods in vogue are those of reduction (aniline from nitrobenzene) and of ammonolysis (aniline from chlorobenzene).

Reduction of groups other than the nitro group in the example named above is possible. Such groups as nitroso (—NO), hydroxylamine (—NHOH), nitrile (—CN), hydrazine (—$NH \cdot NH_2$), hydrazo (—NH·NH—), and azo (—N:N—) yield amines by reduction, but the nitro group is principally employed. The production of aniline from nitrobenzene by reduction with iron and acid (usually hydrochloric) is an outstanding case. Only about 2% of the calculated amount of acid (to produce hydrogen by iron) is required, due to the fact that water plus iron in the presence of ferrous chloride solution (ferrous and chloride ions) functions as the real reducing agent. Insoluble ferroferric oxide, the chief iron-containing product that results from the reaction, is separated by filtration, and the aniline filtrate is made alkaline with sodium hydroxide and distilled. The oxide is also treated to recover its aniline content (it is stated that ½ the time consumed in this recovery is required to secure the last 10% on account of the mechanical quality of the sludge). Considerable heat is evolved in the reducing reaction, and provision must be made for withdrawing the heat in excess of that required to maintain the desired temperature in the apparatus.

Ammonolysis—the use of ammonia—is conducted for the replacement by —NH_2 of (1) halogen (chlorobenzene to aniline), (2) sulfonic acid group (sodium anthraquinone-2-sulfonate to 2-aminoanthraquinone), and (3) oxygen-function compounds (examples later). The production of aniline from chlorobenzene is conducted under high pressure, using excess ammonia—water in the presence of cuprous oxide catalyst at about 200° C. The resulting pressure is of the order of 900 lbs. per sq. in. These conditions of high temperature and high pressure demand specially constructed apparatus such as stainless steel now affords. Under the above conditions ammonia and water (as shown, not ammonium hydroxide) exist separately in the system, so that ammonia and water may each serve as reactants, the former producing aniline and the latter some phenol. Vorozhtzov, who studied this reaction in 1934, reported that 5 moles of ammonia (strength 32% NH_3, 68% H_2O) to 1 mole of chlorobenzene in the presence of 0.1 mole of cuprous oxide at approximately 200° C. yielded:

	In the Aniline Layer Weight (%)	In the Water Layer Weight (%)
Aniline	81 6	4.9
Phenol	4.9	0.3
Diphenylamine	0.9	0.0
Ammonia	Trace	13.8
Chloride ion	Trace	8.8
Cuprous oxide	Trace	2.9

which represents a yield of aniline 86.5% of theory, of phenol 5.2% of theory, and also 0.9% of diphenylamine. Addition of excess sodium hydroxide fixes the phenol as non-volatile sodium phenate and liberates free ammonia and free aniline. Upon distillation ammonia comes off first, and then the aniline—water fraction, from which aniline separates upon cooling. At 15.5° C. (60° F.) the water in the aniline layer is 4.5 weight per cent (density 1.026) and the aniline in the water layer 3.4 weight per cent (density 1.000). Aminoacetic acid is made by the ammonolysis of chloroacetic acid.

In the ammonolysis of benzenoid sulfonic acid derivatives an oxidizing agent is added to prevent the formation of soluble reduction products—$NaNH_4SO_4$ commonly resulting. When the sulfonate is used without an oxidizing agent the yield is low, of the order of 60% of theory. Lauer in 1932 studied the behavior of oxidizing agents on (a) sodium anthraquinone-1-sulfonate. The maximum yield, namely 92%, was obtained by using 1-nitrobenzene-3-sulfonic acid (in amount 120% of theory) as oxidizing agent, and (b) sodium anthraquinone-2-sulfonate. In this case he obtained the maximum yield, namely 83%, using potassium dichromate plus ammonium chloride (in amount 100% of theory).

Oxygen-function compounds that are subjected to ammonolysis are illustrated as follows:

Alcohols: Methanol plus aluminum phosphate catalyst yields mono-, di-, trimethylamines.

Phenols: *beta*-Naphthol plus sodium ammonium *sulfite* catalyst (Bucherer reaction) yields *beta*-naphthylamine.

Oxides: Ethylene oxide yields mono-, di-, triethanolamines.

Aldehydes: Glucose plus nickel catalyst yields glucamine.

Ketones: Cyclohexanone plus nickel catalyst yields cyclohexylamine.

Carbon dioxide: Urea formed at 190° C., 200 atmospheres pressure, in 2 hours from 1 mole of carbon dioxide plus 6 moles of ammonia (three times the theoretical weight of the latter) in silver- or lead-lined apparatus. A mixture of 51 parts by weight of urea, 12 of ammonium carbamate, 68 of ammonia, 15 of water results. By a succession of treatments the final result is 30 parts by weight of urea crystals and mother liquor containing 21 of urea, 12 of ammonium carbamate, 8 of ammonia, 15 of water.

The production of paraffin amines is conducted by heating under pressure the corresponding nitroparaffin with hydrogen gas, especially methyl, ethyl, propyl, butyl amines. Ammonolysis of the corresponding chloro-compounds is also satisfactory, especially with the higher members and with ethylene diamine from ethylene dichloride. (See **Amines.**) (R.K.S.)

AMINES AND AMIDES. Amines are derivatives of **ammonia** in which there is replacement of one or more **hydrogens** of ammonia (NH_3) by an alkyl group, e.g., methyl ($-CH_3$), ethyl ($-C_2H_5$) or an aryl group, e.g., phenyl ($-C_6H_5$), naphthyl ($-C_{10}H_7$). Aniline ($C_6H_5NH_2$) is a familiar and important amine, used in the dyestuff industry. (See **Aniline,** and **Dyes and Dyeing.**) Mixed amines contain at least one alkyl and one aryl group, e.g., methylaniline, methylphenylamine $\left(C_6H_5N\begin{array}{l}\diagup H\\ \diagdown CH_3\end{array}\right)$. When one, two, and three hydrogens are thus replaced, the resulting amines are known as primary, secondary, tertiary, respectively. Methylaniline is, therefore, a secondary and dimethyl aniline a tertiary amine. Quaternary ammonium compounds, e.g., tetramethylammonium iodide, result from the reaction of a tertiary amine, e.g., trimethylamine and an alkyl haloid, e.g., methyl **iodide.** The corresponding hydroxide, tetramethylammonium hydroxide is a strong base, of the order of strength of sodium hydroxide. Amines have a characteristic odor, and many of the alkyl amines are soluble in water.

Amides are derivatives of ammonia in which there is replacement of one or more hydrogens of ammonia by an acyl group, e.g., acetyl ($-COCH_3$), yielding acetamide (CH_3CONH_2), benzoyl ($-COC_6H_5$) yielding benzamide ($C_6H_5CONH_2$). When one, two and three hydrogens are thus replaced, the resulting amides are known as primary, secondary, tertiary, respectively. Tribenzamide is, therefore, a tertiary amide.

The **ionization** constants of some **nitrogen** bases (also **silver** hydroxide) which constants indicate the relative strength of these bases, are as follows, arranged in decreasing basic strength:

Base	Ionization Constant of Base
Piperidine	2×10^{-3}
Diethylamine	1×10^{-3}
Dipropylamine (normal)	1×10^{-3}
Dimethylamine	7×10^{-4}
Brucine	7×10^{-4}
Triethylamine	6×10^{-4}
Ethylamine	6×10^{-4}
Tripropylamine (normal)	6×10^{-4}
Tetramethylenediamine	5×10^{-4}
Methylamine	5×10^{-4}
Propylamine (normal)	5×10^{-4}
Methyldiethylamine	4×10^{-4}
Silver hydroxide	1×10^{-4}
Ethylenediamine	9×10^{-5}
Trimethylamine	7×10^{-5}
Diethylbenzylamine	4×10^{-5}
Benzylamine	2×10^{-5}
Ammonium hydroxide	2×10^{-5}
Dimethylbenzylamine	1×10^{-5}
Hydrazine	3×10^{-6}
Quinine	2×10^{-7}
Pyridine	2×10^{-9}
Para-toluidine	2×10^{-9}
Phenylhydrazine	2×10^{-9}
Quinioline	1×10^{-9}
Meta-toluidine	6×10^{-10}
Aniline	5×10^{-10}
Ortho-toluidine	3×10^{-10}
Ortho-phenylenediamine	3×10^{-10}
Beta-naphthylamine	2×10^{-10}
Alpha-naphthylamine	1×10^{-10}
Semicarbazide	3×10^{-11}
Methyl red	3×10^{-12}
Thiazole	3×10^{-12}
Anthranilic acid	1×10^{-12}
Theobromine	5×10^{-14}
Caffeine	4×10^{-14}
Acetanilide	4×10^{-14}
Urea	2×10^{-14}
Acetamide	3×10^{-15}
Propylcyanide (normal)	2×10^{-15}
Thiourea	1×10^{-15}

The ionization constants of some nitrogen acids (also carbonic and acetic acids) are given for comparion, which constants indicate the relative strength of these

acids, arranged in decreasing basic (increasing acidic) strength:

Acid	Ionization Constant of Acid
Hydrocyanic acid	7×10^{-10}
Cyanuric acid	2×10^{-7}
Carbonic acid	3×10^{-7}
Uric acid	2×10^{-6}
Nicotinic acid	1×10^{-5}
Acetic acid	2×10^{-5}
Hydrazoic acid	2×10^{-5}
Barbituric acid	1×10^{-4}
Hippuric acid	2×10^{-4}
Nitrous acid	4×10^{-4}
Picric acid	2×10^{-1}

Secondary Amides

Amide	Formula	Melting Point °C.	Boiling Point °C.
21. Diacetamide	$(CH_3CO)_2NH$	78	223
22. Dibenzamide	$(C_6H_5CO)_2NH$	148	

Tertiary Amides

Amide	Formula	Melting Point °C.	Boiling Point °C.
23. Tribenzamide	$(C_6H_5CO)_3N$	207	subl.

Imides

Imides	Formula	Melting Point °C.	Boiling Point °C.
24. Succinimide (butamide)	$\begin{matrix} CH_2—CO \\ \vert \\ CH_2—CO \end{matrix}\!\!>\!NH$	125	287
25 Ortho-Phthalimide	$C_6H_4<^{CO}_{CO}>NH$	238	subl.

REPRESENTATIVE COMPOUNDS RELATED TO AMINES AND AMIDES

Carbamates

Carbamate	Formula	Melting Point °C.	Boiling Point °C.
1. Carbamic acid (not isolated)			
2. Methyl carbamate	$OC<^{OCH_3}_{NH_2}$	54	177
3. Ethyl carbamate (urethane)	$OC<^{OC_2H_5}_{NH_2}$	49	184
4. Propylcarbamate (norm.)	$OC<^{OC_3H_7}_{NH_2}$	60	200
5. Phenylcarbamate	$OC<^{OC_6H_5}_{NH_2}$	142	
6. Benzylcarbamate	$OC<^{OCH_2C_6H_5}_{NH_2}$	86	dec.
7. Ethyl-N-methyl carbamate (N-methylurethane)	$OC<^{OC_2H_5}_{NHCH_3}$	....	170
8. Ethyl-N-ethyl carbamate (N-ethylurethane)	$OC<^{OC_2H_5}_{NHC_2H_5}$	....	175
9. Ethyl-N-normal-propyl carbamate (N-normal-propylurethane)	$OC<^{OC_2H_5}_{NHC_3H_7}$	....	192
10. Ethyl-N-phenyl carbamate (N-phenylurethane)	$OC<^{OC_2H_5}_{NHC_6H_5}$	52	237
11. Ethyl-N,N-diphenyl carbamate (N,N-diphenylurethane)	$OC<^{OC_2H_5}_{N(C_6H_5)_2}$	72	>360
12. Thiourethane	$OC<^{SC_2H_5}_{NH_2}$	108	subl.

Ureas

Urea	Formula	Melting Point °C.	Boiling Point °C.
1. Urea	$OC<^{NH_2}_{NH_2}$	133	dec.
2. Methylurea	$OC<^{NHCH_3}_{NH_2}$	101	dec.
3. Dimethylurea (sym.)	$OC<^{NHCH_3}_{NHCH_3}$	106	269

Guanidines

Guanidine	Formula	Melting Point °C.	Boiling Point °C.
1. Guanidine	$HN:C{<}^{NH_2}_{NH_2}$		
2. 1,3-diphenylguanidine	$HN:C{<}^{NHC_6H_5}_{NHC_6H_5}$	147	
3. 1,1,3,3-tetraphenylguanidine	$HN:C{<}^{N(C_6H_5)_2}_{N(C_6H_5)_2}$	130	
4. 1,2,3-triphenylguanidine	$C_6H_5N:C{<}^{NHC_6H_5}_{NHC_6H_5}$	144	
5. 1,1,3-triphenylguanidine	$HN:C{<}^{NHC_6H_5}_{N(C_6H_5)_2}$	131	
6. Guanylurea	$HN:C{<}^{NH_2}_{NHCONH_2}$	105	160 dec.
7. Aminoguanidine	$HN:C{<}^{NHNH_2}_{NH_2}$	dec.	

Primary amines react (1) with **nitrous acid**, yielding (a) with alkyl amine, nitrogen gas plus alcohol, (b) with aryl amine warm, nitrogen gas plus phenol. The amino-group of primary amines is displaced by the hydroxyl group to form **alcohol or phenol,** (c) with aryl amine cold, **diazonium-compounds,** (2) with **acetyl chloride** or **benzoyl chloride,** yielding substituted amide, thus, ethylamine plus acetyl chloride to form N-ethylacetamide ($C_2H_5NHOCCH_3$), (3) with benzene-sulfonyl chloride ($C_6H_5SO_2Cl$), yielding substituted benzene sulfonamides, thus, ethylamine to form N-ethylbenzenesulfonamide ($C_6H_5SO_2NHC_2H_5$), soluble in sodium hydroxide, (4) with **chloroform** ($CHCl_3$) and a base, yielding **isocyanides** (Very poisonous!), (5) with nitric acid concentrated, yielding nitramines, thus, ethylamine to form ethylnitramine ($C_2H_5NHNO_2$). Primary amines may be formed (1) by reduction of **nitro-compounds** (aniline from nitrobenzene), **nitroso-compounds, hydroxylamines, cyanides, oximes** or **hydrazones,** (2) by the alkaline (NaOH) hydrolysis of **isocyanates** (sodium carbonate also formed) or isocyanides (sodium formate also formed), (3) by reaction with **bromine** followed by treatment with sodium hydroxide (Hofmann Reaction) (sodium carbonate and bromide also formed), (4) by reaction of sodium phthalimide plus alkyl halide, followed by heating with fuming hydrochloric acid (Gabriel reaction) (phthalic acid also formed), (5) with vapor of **alcohols** plus **ammonia** in the presence of a **catalyzer,** e.g., **thorium** oxide at 360° C., (6) from aminoacids, by living organisms, e.g., decomposition of fish, in the case of methylamine.

Secondary amines react (1) with nitrous acid, yielding nitrosoamines, yellow oily liquids, volatile in steam, soluble in ether. The secondary amine may be recovered by heating the nitrosoamine with **hydrochloric acid,** concentrated, or **hydrazines** may be formed by reduction of the nitrosamines, e.g., methylaniline forms methylphenylnitrosamine $\left(\begin{matrix}CH_3\\C_6H_5\end{matrix}{>}N\cdot NO\right)$, reduction yielding unsymmetrical methylphenylhydrazine

$$\left(\begin{matrix}CH_3\\C_6H_5\end{matrix}{>}NHNH_2\right)$$

(2) with **acetyl** or **benzoyl chloride,** yielding substituted amide, thus, diethylamine plus acetyl chloride to

form N-N-diethylacetamide ($(C_2H_5)_2NOCCH_3$), (3) with benzene sulfonyl chloride, yielding substituted benzene sulfonamides, thus, diethylamine to form N-N-diethylbenzenesulfonamide ($C_6H_5SO_2N(C_2H_5)_2$), insoluble in sodium hydroxide, (4) with **phenol** warmed with **sulfuric acid** concentrated, then diluted with water and made alkaline with sodium hydroxide, yielding a blue to violet coloration.

Secondary amines may be formed (1) by alkylation of primary amines, using, for example, methyl chloride, dimethyl sulfate, (see **Esters**), **methyl alcohol,** heated, **formaldehyde** in acid medium heated, and may be recovered from mixtures with primary or tertiary amines by means of the nitrosamine reaction above, (2) from **aminoacids** by living organisms, e.g., decomposition of fish, in the case of dimethylamine.

Tertiary amines do not react with nitrous acid, acetyl chloride, benzoyl chloride, benzenesulfonyl chloride, but react with alkyl haloids to form quaternary ammonium haloids, which are converted by silver hydroxide to quaternary ammonium hydroxides. Quaternary ammonium hydroxides upon heating yield (1) tertiary amine plus alcohol (or, for higher members, olefin hydrocarbon plus water). Tertiary amines may also be formed (2) by alkylation of secondary amines, for example, by dimethyl sulfate, methyl alcohol heated, formaldehyde in acid medium heated, (3) from aminoacids by living organisms, e.g., decomposition of fish in the case of trimethylamine. (See **Amination.**)

Primary amides react (1) with **hypobromite** in sodium hydroxide, to form amines, of one carbon less than in the amides (sodium carbonate and bromide also formed). (Ureas yield nitrogen gas plus carbon dioxide with sodium hypobromite), (2) with **nitrous acid,** to form nitrogen gas plus the corresponding **carboxylic acid** (ureas yield carbon dioxide), (3) with **phosphorous** pentoxide, to form cyanides by loss of water, (4) with **sodium** hydroxide, to form ammonia gas plus the corresponding carboxylic acid. Primary amides are formed (1) by reaction of **acid chlorides, acid anhydrides** or **esters** with ammonium hydroxide (for urea, carbonyl chloride is used), (2) by heating the ammonium salt of the desired acid, e.g., ammonium acetate to obtain acetamide, (3) by reaction of **cyanides** with acids, e.g., hydrochloric acid concentrated cold. When amines instead of ammonium hydroxide are used with acid chlorides, acid anhydrides or esters, alkylated amides are obtained, e.g., N-methyl-acetamide ($CH_3CO\cdot NH\cdot CH_3$). Succinimide, it is to be noted, contains the ring of pyrrole, and may be converted into pyrrole by treatment with zinc and acetic acid, or with hydrogen in the presence of finely divided platinum heated.

Urea may be substituted, as to the hydrogens, (1) by alkyl or aryl, mono, di, tetra, most commonly di, symmetrical (1, 3), (2) by carbonyl groups (=CO) either (a) as open chain ureides, e.g., acetylurea ($NH_2CO\cdot NH\cdot OC\cdot CH_3$) or (b) as cyclic ureides, e.g., oxalylurea $\left(\begin{matrix}CO—NH\\ |\\ CO—NH\end{matrix}\!\!>\!CO\right)$. Purine and uric acid compounds contain two of these cyclic ureides, namely oxalylurea and malonylurea, interlocked. Biuret is formed by heating urea at 160° C., and its formation is commonly used as a test for urea. When **sodium** hydroxide plus **copper** sulfate is added to biuret a violet-red color is produced. Urea was the first artificially prepared product of vital processes, by Wöhler, in 1828, by heating ammonium cyanate. Urea is produced in the animal body from **proteins** of food. Mammals execrete urea in the urine, while many other animals excrete nitrogen in the form of uric acid. Werner, in 1923, suggested the formula $HN{:}C\!\left<\begin{matrix}NH_3\\ |\\ O\end{matrix}\right.$ for urea.

Semicarbazide forms salts with **acids,** e.g., semicarbazide hydrochloride ($NH_2CONHNH_2\cdot HCl$), melting point 173° C. dec., reacts with carbonyl group (=CO) of aldehydes and ketones to form semicarbazones, usually of sharp melting point, and useful in identification of **aldehydes** and **ketones.** Semicarbazide is formed by reaction of hydrazine hydrate and sodium cyanate.

Guanidine forms salts with acids, e.g., guanidine nitrate $HNC(NH_2)_2\cdot HNO_3$. By heating at 120° C. for several hours a mixture of **ammonium** thiocyanate and dicyanidiamide, guanidine thiocyanate solution is obtained by extracting with water. Treating guandine with a mixture of nitric and sulfuric acids forms nitroguanidine $\left(HN{:}C\!\left<\begin{matrix}NH\cdot NO_2\\ NH_2\end{matrix}\right.\right)$ which is reduced by zinc and acetic acid to aminoguanidine $\left(HN{:}C\!\left<\begin{matrix}NH\cdot NH_2\\ NH_2\end{matrix}\right.\right)$. By treating aminoguanidine (1) with dilute acid or alkali, there is obtained, first, semicarbazide, finally hydrazine; (2) with nitrous acid, diazoguanidine

$$\left(HN{:}C\!\left<\begin{matrix}NHN{:}NOH\\ NH_2\end{matrix}\right.\right),$$

which is decomposed by alkali into hydrazoic acid (HN_3) plus cyanamide ($H_2N\cdot CN$) plus water. (R.K.S.)

AMINOACIDS, POLYPEPTIDES, AND PROTEINS. Aminoacids are formed by the reaction of water and proteins. Aminoacids correspond to hydroxyacids, the amino-group (—NH_2) occupying the position of the hydroxyl-group (—OH) of the latter. The simplest aminoacid is aminoacetic acid, glycocoll, glycine ($CH_2NH_2\cdot COOH$) corresponding to hydroxyacetic acid, glycollic acid ($CH_2OH\cdot COOH$). Aminoacetic acid reacts (1) with **bases,** to form sodium aminoacetate ($CH_2NH_2\cdot COONa$), (2) with **acids,** to form aminoacetic acid hydrochloride ($HCl\cdot CH_2NH_2COOH$), (3) with **formaldehyde,** to form $CH_2{:}NCH_2\cdot COOH$, which can be **titrated** as an acid by a standard base, (4) with **alcohols** anhydrous plus **hydrogen chloride,** followed by treatment with **sodium** hydroxide solution cold, extraction with **ether,** and evaporation of ether, to form, for example the **ester** O-methylaminoacetate (CH_2NH_2-$COOCH_3$), boiling point 130° C., decomp. Such esters are useful in the separation of aminoacids, (5) with **benzoyl chloride,** to form N-benzoylaminoacetic acid, hippuric acid ($C_6H_5CO\cdot NHCH_2\cdot COOH$), (6) with **acetyl chloride** in large excess at 0° to 20° C. plus phosphorus pentachloride, to form $HCl\cdot H_2N\cdot H_2C\cdot COCl$. Such compounds are useful in the synthesis of polypeptides, (7) with **nitrous acid,** to form glycollic acid plus nitrogen, (8) with phenyl isocyanate (C_6H_5NCO), to form phenyl ureidoacetic acid ($C_6H_5NHCONHCH_2\cdot COOH$), slightly soluble. Such compounds from phenyl isocyanate and from alpha-naphthylisocyanate are useful in the separation of aminoacids, (9) with **copper** carbonate by boiling in aminoacetic acid solution, to form dark blue copper aminoacetate ($(CH_2NH_2\cdot COO)_2Cu\cdot H_2O$). N-methylaminoacetic acid, sarcosine $\left(\begin{matrix}CH_3\\ H\end{matrix}\!\!>\!N\cdot CH_2COOH\right)$ is formed when creatine (methylguanidylacetic acid, $HN{:}C\!\left<\begin{matrix}NH_2\\ N\!\left<\begin{matrix}CH_3\\ CH_2\cdot COOH\end{matrix}\right.\end{matrix}\right.$) of meat juice is warmed with barium hydroxide solution.

Aminoacids may be prepared (1) by reaction of halogen-substituted acids (or their esters) with ammonia, e.g., chloroacetic acid ($ClCH_2\cdot COOH$) to form aminoacetic acid ($H_2NCH_2\cdot COOH$), (2) by reaction of **aldehydes or ketones with hydrogen cyanide** to form aldehyde or ketone cyanhydrin, e.g., acetaldehyde cyan-

hydrin ($CH_3 \cdot CHOH \cdot CN$), which by reaction with ammonia forms aminocyanide ($CH_3CHNH_2 \cdot CN$), and then by hydrolysis this forms the corresponding aminoacid ($CH_3CHNH_2 \cdot COOH$), (3) by reaction of proteins with hydrochloric acid, the aminoacid residues constituting the protein are obtained. The aminoacids thus obtained from proteins are alpha-substituted aminoacids. Some of the most important alpha-aminoacids in this connection are:

SELECTED REPRESENTATIVE ALPHA-AMINO ACIDS

	Alpha-Amino Acid	Formula
1.	Aminoacetic acid (glycocoll, glycine)	CH_2NH_2COOH
2.	N-methylaminoacetic acid (sarcosine)	CH_3NHCH_2COOH
3.	Alpha-aminopropionic acid (alanine)	$CH_3CH_2NH_2COOH$
4.	Alpha-amino-beta-hydroxy-propionic acid (serine)	$CH_2OHCHNH_2COOH$
*5.	Alpha-aminoisocaproic acid (leucine)	$(CH_3)_2CHCH_2CHNH_2COOH$
*6.	Alpha-amino-beta-methylvaleric acid (isolucine)	$\begin{matrix}C_2H_5\\CH_3\end{matrix}\!>\!CHCHNH_2COOH$
7.	Alpha-aminosuccinic acid (aspartic acid)	$COOHCH_2CHNH_2COOH$
8.	Alpha-aminoglutaric acid (glutamic acid)	$COOHCH_2CH_2CHNH_2COOH$
9.	Alpha-amino-delta-guanidine-valeric acid (arginine)	$HN{:}C\!<\!\begin{matrix}NH_2\\NHCH_2CH_2CH_2CHNH_2COOH\end{matrix}$
*10.	Alpha-epsilon-diaminocaproic acid (lysine)	$CH_2NH_2CH_2CH_2CH_2CHNH_2COOH$
11.	Bi-alpha-amino-beta-thiopropionic acid (cystine)	CH_2S——SCH_2 $CHNH_2$ $CHNH_2$ $COOH$ $COOH$
*12.	Alpha-amino-beta-phenylpropionic acid (phenylalanine)	13.	Alpha-amino-beta-parahydroxyphenylpropionic acid (tyrosine)	14.	Alpha-pyrrolidine carboxylic acid (proline)	*15.	Alpha-amino-beta-imideazolepropionic acid (histidine)	*16.	Alpha-amino-beta-indolepropionic acid (tryptophane)	*17.	Alpha-aminoisovaleric acid (valine)	$(CH_3)_2CHCHNH_2COOH$
*18.	Alpha-amino-beta-hydroxybutyric acid (threonine)	$CH_3CHOHCHNH_2COOH$
*19.	Alpha-amino-gamma-methylthiolbutyric acid (methionine)	$CH_3 \cdot S \cdot CH_2CH_2CHNH_2COOH$

* These acids have been shown by Rose to be essential in the diet of the growing rat or dog, based on experiments covering a period of about 6 weeks.

Phenylalanine, tyrosine, tryptophane are benzenoid compounds and consequently react readily with **nitric acid** to form yellow nitro-compounds. They are responsible for the yellow xanthroproteic reaction of proteins with concentrated nitric acid.

Tyrosine is a phenolic compound and consequently reacts with nitric acid to form upon boiling with nitrous acid plus **nitric acid** plus **mercurous** salt plus mercuric salt (Millon's solution) a brick-red color.

Tryptophane, when treated with glyoxylic (glyoxalic) acid ($CHO \cdot COOH$), and stratified by concentrated **sulfuric acid** forms a violet color at the junction of the liquids. Glyoxylic acid is made by reduction of **oxalic acid** solution by **sodium** amalgam.

Cystine contains sulfur, reacts with **sodium** hydroxide warm to form sodium sulfide, which with **lead** nitrate solution forms a black precipitate of lead sulfide.

When amino- or hydroxyacids lose ammonia, or water, respectively, characteristic reactions occur, as shown at top of page 77.

Aminoacids may be combined with one another, up to 19 aminoacid units, to form polypeptides, thus: alpha-aminopropionic acid, alanine ($CH_3CHNH_2 \cdot COOH$), by reaction with aminoacetic acid, glycine ($CH_2NH_2 \cdot COOH$) forms alanylglycine (CH_3CHNH_2—CO—NH—$CH_2 \cdot COOH$) in which the peptide group (—CO—NH—) serves to unite the two nuclei. In the reverse direction, alanylglycine can be caused to react with water to form alanine plus glycine, the disruption occurring at the peptide grouping.

Aminoacids are of great importance on account of being constituents, through the peptide group, of naturally occurring proteins of plants and animals. The percentage of **nitrogen** element found in proteins varies between the limits 15.0 and 17.6, of **sulfur** between 0.5 and 2.2, and of **phosphorus** between 0.4 and 0.9. Proteins are important **food** materials and are characterized by the above nitrogen content, being in this way distinguished from the other grand classes of food mate-

Amino- or Hydroxyacid	Formula	Product
Alpha-amino	CH_2NH_2COOH	Lactim: CH_2—NH—CO / CO—NH—CH_2 (ring)
Beta-amino	$CH_2NH_2CH_2COOH$	Unsaturated acid: $CH_2 : CHCOOH$
Gamma-amino	$CH_2NH_2 \cdot CH_2CH_2COOH$	Gamma-lactam: $CH_2CH_2CH_2CO$ with —NH— closing the ring
Alpha-hydroxy	$CH_3CHOHCOOH$	Lactide: H_3CCH—CO—O / O—CO—$HCCH_3$ (ring)
Beta-hydroxy	$CH_3 \cdot CHOH \cdot CH_2COOH$	Unsaturated acid: $CH_3CH : CH \cdot COOH$
Gamma-hydroxy	$CH_3 \cdot CHOH \cdot CH_2 \cdot CH_2 \cdot COOH$	Gamma-lactone: $CH_3CHCH_2CH_2CO$ with —O— closing the ring

rials, namely, fats, carbohydrates. Proteins are among the most important constituents of the living **cell**, and intimately connected with life processes. Each type of organism and each kind of cell within the organism possess their own characteristic proteins. Proteins are essential constituents of animal diet, and cereal grains, legumes, eggs, milk, cheese and meat are outstanding food sources of proteins. Wool, hair, silk, and skin are also proteins. Some proteins, such as keratin of hair and horn, are not broken down by the **enzymes** of the alimentary canal, and are thus not utilizable as foods. Certain proteins have important industrial uses. These are wool, silk, skins and hides for leather, hair, gelatin, casein for plastics, glue and casein for adhesives.

COMPOSITION OF CHIEF PROTEIN FOODS

	Protein, %	Fat, %	Carbohydrate, %
Wheat	8–17	1.5–4	65–79
Corn	7.5–13	3–7.5	65–76
Oats	12–14	5–8	67
Rice	8	2	77
Peas, dried	25	1	62
Beans, dried	23	2	60
Potatoes	1.4–2.8	0.2–0.4	15–29
Bananas	1.5	0.5	22
Apples	0.4	0.5	14
Peanuts	26	40	22
Milk	3.5	4	5
Butter	1	85	
Cheese, cream	26	37	3
Cheese, cottage	21	1	4
Beef, raw	19	19	
Eggs	15	11	

Proteins are complexes, which contain alpha-amino-acids united by peptide linkage (—CO·NH—). Unlike dissolved sugars, proteins do not diffuse through animal membranes, and, except for **aleurone** grains in the seeds of plants, are not found crystallized, and are only obtained crystalline with great difficulty. Proteins possess the acid-base characteristics of aminoacids, and the properties of protein solutions depend to a large degree upon the **hydrogen-ion** concentration. At the **isoelectric point**, which is characteristic of each protein, it is found that optimum conditions exist for coagulation of proteins by heating. Proteins are coagulated not only by heating, as in the familiar case of egg albumin, which coagulation is not reversible, but also by addition of **sodium, potassium** or **ammonium** salts, which, at a definite concentration of salt in solution, precipitate proteins. Thus precipitated, the protein retains its original propertes, and, by filtration and dissolving out of the salt, may be obtained in its original condition. The precipitation is thus reversible. The addition of certain substances, such as **alcohol, acetone, tannic acid,** or salts of heavy metals (for instance, mercuric chloride), causes irreversible precipitation.

The coagulation of proteins by heat is also affected by the presence of salts, small quantities of salts usually raise the coagulation temperature, and large quantities lower it.

A system of classification of proteins has been adopted by the American Society of Biochemists.

Proteins, in general, give positive reactions in many of the tests described under aminoacids, for example, (1) xanthoproteic acid reaction with **nitric acid** concentrated, the yellow color being changed orange by alkalis, (2) Millon's reaction, (3) glyoxylic acid reaction, (4) biuret reaction, by the reaction of protein in sodium hydroxide solution plus copper sulfate a violet red color is produced, (5) sulfur reaction of cystine. Proteins are precipitated in acid solution by phosphotungstic acid, **tannic acid, picric acid,** and hydroferrocyanic acid, and, in neutral or slightly alkaline solution, by salts of certain metals, such as **cupric, mercuric, lead, gold,** and **ferric.** Proteins are usually present in plant and animal materials in the colloidal state.

The data on page 78 on the composition of some proteins is selected from the work of Mitchell and Hamilton (1929). (R.K.S.)

AMINOAZO-COMPOUNDS. Azo-, Diazo-, and Related Compounds.

AMINOGUANIDINES. Amines and Amides.

AMITOSIS. Cell Division.

AMMETER. An instrument for measuring electric currents in amperes. D-c ammeters are usually of the moving-coil type, being similar in principle to the d'Arsonval **galvanometer.** A coil carrying the current to be measured turns between the poles of a permanent magnet against the torque of a hair-spring and causes a pointer to move over its dial. A-c ammeters commonly have two coreless coils in series, one turning in the field set up by the other which is fixed (electrodynamometer type). The reversal of current thus has no effect upon the direction of the torque. Some simple ammeters are of the hot-wire type, in which the longitudinal expansion of the wire carrying the current controls the movement of the pointer. For currents heavier than the coil or the hot wire can safely stand, a shunt may be provided in d-c ammeters, which allows only a prede-

termined fraction of the current to pass through the instrument; while a small transformer serves a similar purpose with a-c ammeters. Very sensitive ammeters, graduated in milliamperes, are called milliammeters. Very feeble currents are commonly measured by a microammeter of the **vacuum thermocouple** type. (L.D.W.)

AMMINES. Dry **ammonia** gas reacts with dehydrated salts of some of the metals to form solid ammines. Ammines, upon warming, evolve ammonia, sometimes with final decomposition of the salt itself, in a manner analogous to the decomposition of certain hydrates. The ammines of **chromic** (Cr^{+3}), **cobaltic** (Co^{+3}), **platinic** (Pt^{++}) and other metals have been studied in detail. Two series of ammines are shown below, the first one in which the neutral ammonia group is replaced step by step by the negative nitro group (NO_2^{-1}), and the second one in which the neutral ammonia group is replaced step by step by the neutral H_2O group.

Number of Neutral Groups, e.g., (NH_3), on Metal, e.g., Co, varied from 6 to 0.

Square bracket contains the ion. Equivalent electrical conductivity inserted below each compound.

$[Cr(NH_3)_6]X_3$
$[Cr(NH_3)_5(H_2O)]X_3$
$[Cr(NH_3)_4(H_2O)_2]X_3$
$[Cr(NH_3)_3(H_2O)_3]X_3$
$[Cr(NH_3)_2(H_2O)_4]X_3$

The neutral group of the complex may be replaced step by step by the following negative groups: Cl^-, Br^-, I^-, F^-, OH^-, NO_2^-, NO_3^-, CN^-, CNS^-, SO_4^{--}, CO_3^{--}, $C_2O_4^{--}$; or by the following neutral groups: H_2O, NO, NO_2, SO_2, S, N_2H_4, H_2NOH, CO, C_2H_5OH, C_6H_6. All neutral groups are of substances capable of independent existence.

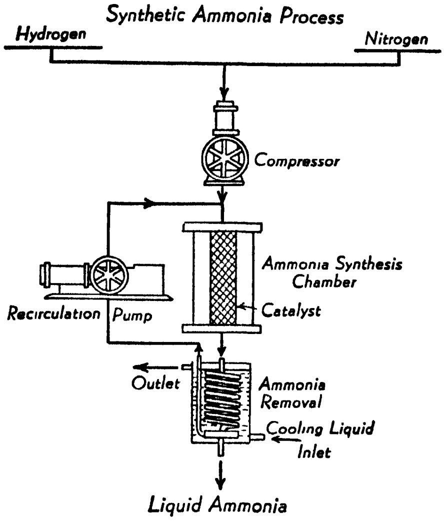
In the ammines, trivalent metals, such as **cobaltic** and **chromic** above, possess a coordination number of 6, this number being the sum of the unit replacements on the metal in the complex ion. Since a regular octahedron has six corners equidistant from the center, it is assumed that the metal occupies the center and each of the six replacing groups occupies a corner of a regular octahedron. Support for this assumption is offered by the **x-ray** examination of these ammines. When there is only one of the six groups replaced by a second group, as in $[Co(NH_3)_5(NO_2)]Cl_2$, and in $[Cr(NH_3)_5(H_2O)]X_3$ the octahedral placement of groups supplies only one form, but when two of the six groups are replaced by a second group, as in $[Co(NH_3)_4(NO_2)_2]Cl$, and in $[Cr(NH_3)_4(H_2O)_2]X_3$, two different octahedral corner arrangements are possible depending upon whether the two replacing groups are adjacent (cis-form) or opposite (trans-form). Two substances differing in physical properties and corresponding to these two forms are known. Further, when three divalent groups, e.g., $3C_2O_4^{--}$ are present in the complex, two arrangements—not identical but mirror-images of each other—are possible. Two optically active substances are known in such cases corresponding to these two sterisomeric forms.

Six is the ordinary coordination number for metallic ammines and similar complexes. Additional examples are $K_2[Pt(NH_3)_2(CN)_4]$, $[Ni(NH_3)_6]Cl_2$, $K_4[Fe(CN)_6]$, $K_3[Fe(CN)_6]$, $K_2[Fe(Cn)_5(NO)]$, $K_2[SiF_6]$, $[Ca(NH_3)_6]Cl_2$. But, for the elements boron, carbon, and nitrogen four is the coordination number, e.g., $[BH_4]Cl$, $[CH_4]$, $[NH_4]Cl$, and in these substances the groups are assumed to occupy the corners of a regular tetrahedron; in $K_4[Mo(CN)_8]$ and $[Ba(NH_3)_8]Cl_2$ the coordination number is eight, and the groups are assumed to occupy the corners of a cube. (R.K.S.)

AMMONIA. Ammonia (NH_3) is a colorless gas, of characteristic choking odor, density 0.7710 gram per liter, 0° C., 760 mm., or 0.60 when air equals 1.00, melting point −78° C., boiling point −33° C., critical temperature 132° C., critical pressure 112 atmospheres, most soluble of the common gases (about 30% NH_3, 70% water, at room temperature and pressure).

Ammonia is used in solution (1) as an important **alkali** and (2) in producing ammonium compounds; as liquid (3) in refrigeration, and (4) as a **solvent** for certain substances; as gas (5) in local production of **hydrogen** by thermal decomposition for use in high temperature combustion, and (6) in the manufacture of **nitric acid** by incomplete combustion with air over heated platinum.

Ammonia is formed (1) in the destructive distillation of **coal** in the production of coke and coal gas, and is recovered from the gas by dissolving in water, and then



Diagrammatic representation of the manufacture of ammonia from hydrogen and nitrogen.

distilling, (2) by reaction of **nitrogen** and hydrogen gases under pressure at elevated temperature in the presence of a **catalyzer** (see graph). Since the gases must be pure for this reaction to take place the resulting ammonia is of high purity, and may be directly liquefied, dissolved in water, or used as gas. When passed over heated **magnesium,** ammonia gas yields hydrogen gas and magnesium nitride (yellow solid, evolving ammonia

Graph showing ammonia equilibria.

with water), and when passed over heated cupric oxide, yields nitrogen gas, water, and finely divided **copper** metal. The reactions commonly assigned to ammonia as a base are given under **Ammonium.** (R.K.S.)

AMMONOLYSIS. Amination.

AMMONITE. Invertebrate Paleontology.

AMMONIUM. Radical: NH_4 The chemical radical ammonium (NH_4) is composed of **nitrogen and hydrogen** and it commonly behaves as a unit. Thus, it forms a series of ammonium salts which resembles the corresponding **potassium** salts. The radical should be distinguished carefully from ammonia (NH_3), which is a gas of separate existence (see **Ammonia**), whereas ammonium is encountered in compounds, such as ammonium chloride (NH_4Cl). When a concentrated water solution of ammonium chloride is electrolyzed, using a **mercury** cathode at 0° C., mercury ammonium amalgam, resembling sodium amalgam, is formed. When warmed above 0° C., there are formed mercury, ammonia, and hydrogen.

Acetate: Ammonium acetate ($NH_4C_2H_3O_2$), white solid, soluble, formed by reaction of ammonia or ammonium hydroxide and **acetic acid,** reacts upon heating to yield acetamide.

Alum: Ammonium alums are those alums, such as **aluminum** ammonium sulfate ($Al_2(SO_4)_3 \cdot (NH_4)_2SO_4 \cdot 24H_2O$), **ferric** ammonium sulfate ($Fe_2(SO_4)_3 \cdot (NH_4)_2SO_4 \cdot 24H_2O$), **chromium** ammonium sulfate ($Cr_2(SO_4)_3 \cdot (NH_4)_2SO_4 \cdot 24H_2O$) where ammonium sulfate is crystallized with the heavier metal sulfate.

Benzoate: Ammonium benzoate ($NH_4C_7H_5O_2$), white solid, soluble, formed by reaction of ammonium hydroxide and **benzoic acid.** Used (1) as a food preservative, (2) in medicine.

Borate: Ammonium borate, ammonium tetraborate ($(NH_4)_2B_4O_7 \cdot 4H_2O$), white solid, soluble, formed by reaction of ammonium hydroxide and **boric acid.** Used (1) in fireproofing fabrics, (2) in medicine.

Bromide: Ammonium bromide (NH_4Br), white solid, soluble, sublimes at 542° C., formed by reaction of ammonium hydroxide and **hydrobromic acid.** Used in photography.

Carbonates: Ammonium carbonate, sal volatile ($(NH_4)_2CO_3$), white solid, soluble, formed by reaction of ammonium hydroxide and **carbon dioxide** by crystallization from dilute alcohol, loses ammonia, carbon dioxide, and water at ordinary temperatures, rapidly at 58° C.; ammonium hydrogen carbonate, ammonium bicarbonate, ammonium acid carbonate (NH_4HCO_3), white solid, soluble, formed by reaction of ammonium hydroxide and excess carbon dioxide. This salt is the important reactant in the ammonia soda process for converting **sodium** chloride in solution into sodium hydrogen carbonate solid.

Chloride: Ammonium chloride, sal ammoniac, muriate of ammonia (NH_4Cl), white solid, soluble, sublimes at 520° C., formed (1) as a white smoke by reaction of ammonia gas and **hydrogen chloride** gas, (2) by reaction of ammonium hydroxide and hydrochloric acid, and then evaporating. Used (1) as an important nitrogenous fertilizer, (2) in dry cell electric batteries, (3) in soldering flux, (4) in the textile and tanning industries.

Chloroplatinate: Ammonium chloroplatinate ($(NH_4)_2PtCl_6$), yellow solid, insoluble, formed by reaction of soluble ammonium salt solutions and **chloroplatinic acid.** Used in the quantitative determination of ammonium.

Cobaltinitrite· Diammonium sodium cobaltinitrite ($(NH_4)_2NaCo(NO_2)_6 \cdot H_2O$) golden yellow precipitate, formed by reaction of sodium cobaltinitrite solution in acetic acid with soluble ammonium salt solution. Used in the detection of ammonium.

Cyanate: Ammonium cyanate (NH_4CNO), white solid, soluble, formed by fractional crystallization of **potassium** cyanate and ammonium sulfate (ammonium cyanate is soluble in alcohol), when heated changes into urea (the classical experiment by Wöhler in 1828).

Dichromate: Ammonium dichromate ($(NH_4)_2Cr_2O_7$), red solid, soluble, upon heating evolves nitrogen gas and leaves a green insoluble residue of **chromic** oxide.

Fluoride: Ammonium fluoride (NH_4F), white solid, soluble, formed by reaction of ammonium hydroxide and **hydrofluoric acid,** and then evaporating. Used (1) as an antiseptic in brewing, (2) in etching glass; ammonium hydrogen fluoride, ammonium bifluoride, ammonium acid fluoride (NH_4F_2), white solid, soluble.

Hydroxide: Ammonium hydroxide (NH_4OH), colorless solution, by solution of (1) ammonia gas in water, commercially of strength 26° Baumé (Specific gravity at 66° F., water at 60° F., 0.8974), 29.40% NH_3, (2) anhydrous liquid ammonia (in cylinders). Used (1) as a mild, moderately cheap alkali, e.g., laundering, (2) as a source of ammonium for many salts, (3) as an

important chemical reagent. (See **Reactions Involving Recombination of Ions.**)

Iodide: Ammonium iodide (NH_4I), white solid, soluble, formed by reaction of ammonium hydroxide and **hydriodic acid,** and then evaporating. Used (1) in photography, (2) in medicine.

Linoleate: Ammonium linoleate ($NH_4C_{18}H_{31}O_2$). Used (1) as an emulsifying agent, (2) as a detergent.

Nitrate: Ammonium nitrate, nitrate of ammonia (NH_4NO_3), white solid, soluble, melting point 170° C., formed (1) by fractional crystallization of ammonium sulfate or chloride and **sodium nitrate,** (2) by reaction of ammonium hydroxide and **nitric acid,** and then evaporating. Used (1) in the preparation of nitrous oxide gas (by heating), (2) in explosives, pyrotechnics, (3) in freezing mixtures of salts.

Nitrite: Ammonium nitrite (NH_4NO_2) when ammonium sulfate or chloride and sodium or potassium nitrite are heated, the mixture behaves like ammonium nitrite in yielding nitrogen gas.

Oxalate: Ammonium oxalate ($(NH_4)_2C_2O_4$), white solid, soluble, formed by reaction of ammonium hydroxide and **oxalic acid,** and then evaporating. Used as a source of oxalate; ammonium binoxalate ($NH_4HC_2O_4 \cdot H_2O$), white solid, soluble.

Perchlorate: Ammonium perchlorate (NH_4ClO_4), white solid, soluble, formed by reaction of ammonium hydroxide and **perchlorate acid,** and then evaporating. Used in explosives and pyrotechnics.

Periodate: Ammonium periodate (NH_4IO_4), white solid, moderately soluble.

Persulfate: Ammonium persulfate ($(NH_4)_2S_2O_8$), white solid, soluble, formed by **electrolysis** of ammonium sulfate under proper conditions. Used (1) as a bleaching and oxidizing agent, (2) in electroplating, (3) in photography.

Phosphate: Diammonium hydrogen phosphate ($(NH_4)_2HPO_4$), white solid, soluble, formed by reaction of excess ammonium hydroxide and **phosphoric acid,** and then evaporating at room temperature. Used (1) in fireproofing, (2) as a fertilizer supplying nitrogen and phosphorus, (3) in medicine; ammonium dihydrogen phosphate ($NH_4H_2PO_4$), white solid, soluble, formed by heating diammonium phosphate to 155° C.

Phosphomolybdate: Ammonium phosphomolybdate, ($(NH_4)_3PO_4 \cdot 12MoO_3$ or similar composition), yellow precipitate, soluble in alkalis, formed by excess ammonium molybdate and nitric acid with soluble phosphate solution. Used as an important test for phosphate (similar product and reaction when arsenate replaces phosphate).

Salicylate: Ammonium salicylate ($NH_4C_7H_5O_3$), white solid, soluble, formed by reaction of ammonium hydroxide and **salicylic acid,** and then evaporating. Used in medicine.

Sulfate: Ammonium sulfate, sulfate of ammonia ($(NH_4)_2SO_4$), white solid, soluble, formed by reaction of ammonium hydroxide and **sulfuric acid,** and then evaporating. Used (1) as an important nitrogenous **fertilizer,** largely obtained by recovery of ammonia from by-product coke oven operations, (2) as a soldering liquid, (3) in fireproofing fabrics, (4) in electric dry cell batteries, (5) as a source of ammonia; ammonium hydrogen sulfate, ammonium bisulfate, (NH_4HSO_4), white solid, soluble, melting point 147° C.

Sulfide: Ammonium sulfide ($(NH_4)_2S$), colorless to yellowish solution, formed by saturation with **hydrogen sulfide** of one-half of a solution of ammonium hydroxide, and then mixing with the other half of the ammonium hydroxide. Dissolves sulfur to form ammonium polysulfide, yellow solution. Used as a reagent in analytical chemistry; ammonium hydrogen sulfide, ammonium bisulfide, ammonium acid sulfide (NH_4HS), colorless to yellowish solution, formed by saturation with hydrogen sulfide of a solution of ammonium hydroxide.

Tartrate: Ammonium tartrate ($(NH_4)_2C_4H_4O_6$), white solid, moderately soluble, formed by reaction of ammonium hydroxide and **tartaric acid,** and then evaporation. Used in the textile industry; ammonium hydrogen tartrate, ammonium bitartrate, ammonium acid tartrate ($NH_4HC_4H_4O_6$), white solid, slightly soluble, formation sometimes used in detection of ammonium or tartrate.

Thiocyanate: Ammonium thiocyanate, ammonium sulfocyanide, ammonium rhodanate (NH_4CNS), white solid, soluble, absorbs much heat on dissolving with consequent marked lowering of temperature, melting point 150° C., formed by boiling ammonium cyanate solution with sulfur, and then evaporating. Used (1) as a reagent for ferric, (2) in making cooling solutions, (3) to make thiourea.

Ammonium compounds liberate ammonia gas when warmed with sodium hydroxide solution. (R.K.S.)

AMNESIA. A loss or lack of memory. Amnesia may be produced by organic or psychogenic factors. In *organic* amnesia, infection, toxins, trauma, or degenerative changes affecting the central nervous system interfere with association processes, and memory is therefore impaired. In *psychogenic* amnesia, memory is suppressed for psychologic reasons. Thus an unfortunate or distasteful experience may be so repressed that amnesia results. A common form is due to conflict of wishes and is expressed by an individual unconsciously forgetting to perform some task which is unpleasant for him. A sudden and complete recovery of memory not infrequently occurs with psychogenic amnesia, but in the organic variety recovery is slow and rarely complete. (D.M.H.)

AMNION. An accessory embryonic membrane common to reptiles, birds and mammals and a superficially similar structure found in some insects.

To the three vertebrate classes, all fundamentally terrestrial, the amnion gives the name **Amniota.** In this group the amnion is usually formed by the growth of folds of the somatopleure, consisting of ectoderm and somatic mesoderm, about the **embryo.** The union of the folds produces two membranes, the outer **serosa** and the inner amnion; the latter encloses the embryo and is filled with amniotic fluid which protects it against desiccation and equalizes mechanical stresses. The amnion is lined with ectoderm and covered with mesoderm, both continuous with the same tissues of the embryo itself.

In the insect egg the amnion develops from folds of ectoderm which extend between the embryo and the shell of the egg and fuse to form an outer serosa and an inner amnion. These structures are not uniform in their appearance and are not persistent throughout embryonic development in all species in which they form, hence their functions are in doubt. (A.W.L.)

AMNIOTA. The classes **Reptilia, Aves,** and **Mammalia** of the vertebrates, in which an **amnion** appears during embryonic development. (A.W.L.)

AMOEBA. A genus of one-celled animals in which the body consists of a naked mass of **protoplasm** and the organs of locomotion are temporary blunt protuberances of cytoplasm (see **Cell**) known as pseudopodia. (See **Pseudopodium.**) (A.W.L.)

AMOEBIC DYSENTERY. Dysentery.

AMOEBULAE. Spores of amoeboid form which are produced by some 1-celled animals. (A.W.L.)

AMORPHOUS. As applied to minerals and rocks this term means: having no definite crystalline structure (texture). (R.M.F.)

AMORTISSEUR WINDING. Damper Winding.

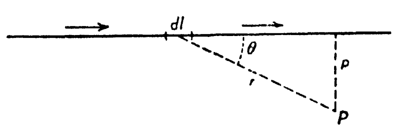
AMOSITE. Amosite is a long fiber gray or greenish asbestiform mineral related to **anthophyllite,** found in South Africa. (E.S.C.S.)

AMPERE. The ampere is the practical unit of electric current. It is primarily an electromagnetic unit, the absolute ampere being defined as $\frac{1}{10}$ of the **abampere.** For reasons of expediency in standardization measurements, however, another basis has been adopted in the definition of the international ampere, which is one international **coulomb** per sec.; i.e., that current which would deposit silver at the rate of 0.001118 gram per sec. from a silver nitrate solution in a **coulombmeter** under prescribed conditions. This electrolytic unit of current is slightly less than the absolute ampere (by about 14 parts in 100,000), but the difference is commonly overlooked in practical measurements. Since the ampere is rather large for many laboratory purposes (a 50-watt, 110-volt lamp requires less than half an ampere), the milliampere (1/1000 ampere) and even the microampere (1/1,000,000 ampere) are often found convenient. (L.D.W.)

AMPERE-HOUR. An ampere-hour is a quantity of electricity, equal to 3600 **coulombs,** viz., the electricity flowing in one hour past any point of a circuit carrying one ampere. It is not a measure of quantity of electrical energy, since voltage does not enter into the product of amperes times hours. The use of the ampere-hour is confined largely to **storage battery** practice (See **Storage Battery.**) Storage batteries are rated in ampere-hours to show the quantity of electricity that can be used without discharging the battery beyond safe limits. The quantity may be measured by an ampere-hour meter. (F.T.M.)

AMPÈRE'S LAW. This is a classic law of electromagnetism, useful in discussions of electrodynamics It has been stated in two apparently distinct forms, which are, however, interconvertible.

One form, sometimes known as **Laplace's law,** states that the electric current i (**abamperes**), flowing along



Current in element dl produces magnetic field at point P.

any line through an element of length dl, gives rise, at a point P distant r (cm) from the element, to a magnetic field of intensity $dH = ipdl/r^3$ (**oersteds**), in which p is the perpendicular distance from P to the line of the element dl; or $dH = i \sin \theta dl/r^2$, in which θ is the angle between the line of the element and the line joining dl to P. The ultimate basis of the law is, of course, experimental. It may, for example, be deduced indirectly from the **Biot-Savart** law for the field about an infinitely long, straight wire. Ampère's law furnishes a basis for the solution of all problems relating to the magnetic fields produced by electric currents.

What is sometimes called the circuital form of Ampère's law may be tangibly expressed by saying that if a unit magnetic pole is carried completely around a conductor or system of conductors in which electricity is flowing, in such a way as to oppose the field set up by the currents, the work done, in **ergs,** is 4π times the algebraic sum of the currents, in abamperes. This is easily illustrated by a special case. The Biot-Savart law above referred to gives, as the magnetic intensity at a point distant r (cm.) from an infinitely long, straight wire carrying a current i (abamperes), the value $H = 2i/r$ (oersteds), directed, of course, along the circumference of the circle having r as its radius. The force acting upon a unit pole placed at this point is therefore $2i/r$ (**dynes**). If now the pole is moved around the circle, against the field, the work done is

$$\frac{2i}{r} \times 2\pi r = 4\pi i \text{ (ergs)}.$$

Maxwell pointed out that Ampère's law holds only for constant currents, and that when currents vary, the resulting changes of electric displacement in the surrounding space, giving rise to the radiation of energy in the form of electromagnetic waves, involves modifications embodied in the so-called Maxwell-Ampere law as expressed by the first of **Maxwell's equations.** (L.D.W.)

AMPHIBIA. The **frogs, toads, newts, salamanders** and related forms. A class of the phylum **Chordata.** Since these animals live only in moist places their distribution is restricted and they are among the less familiar vertebrates.

The amphibians are distinguished by: 1. Moist skin. 2. The absence of scales and claws. 3. Most species undergo a metamorphosis during development from an aquatic, gill-breathing larva to a semi-terrestrial, air-breathing adult stage.

While some of the salamanders are permanently aquatic and some of the tree frogs permanently terrestrial, most members of the class live near the water or in moist places and undergo the metamorphosis mentioned above.

The following orders of amphibians are recognized:

Order **Gymnophiona** (Apoda). Legless, worm-like animals, confined to the tropics of the Old and New Worlds.

Order **Urodela** (Caudata). Elongate animals with long tails and weak, short legs. The **salamanders, newts, efts, hellbender,** and **mud puppy.**

Order **Anura** (Salientia). Tailless species whose hind legs are the larger pair, more or less strongly developed for jumping. Most species have a larval stage known as the tadpole with a compact body and a long compressed tail but no legs until the onset of metamorphosis. The **frogs** and **toads.** (A.W.L.)

AMPHIBIAN AIRPLANE. Seaplane.

AMPHIBOLE. This is the name given to a closely related group of minerals all showing in common a prismatic cleavage of 54–56° as well as similar optical characteristics and chemical composition.

The amphiboles may be said to represent chemically a series of **metasilicates** corresponding to the general formula $RSiO_3$ where R may be **calcium, magnesium, iron, aluminum, titanium, sodium** or **potassium.** The crystals of the amphiboles may be in one of the three systems, **orthorhombic, monoclinic** or **triclinic.**

There is a clear parallelism between the amphiboles and the **proxenes.** The chief difference between the minerals of these two groups lies in the cleavage angles of 56° and 124° for amphibole and 87° and 93° for pyroxene. Amphibole crystals are usually long and slender and tend to be simple while pyroxene crystals tend to be complex, short and stout prisms.

Amphibole is common in both lavas and deep-seated rocks, though less so in the basic lavas than pyroxene. Many of the amphiboles may be developed as metamorphic minerals. The following members of the amphibole group are described under their own headings: **actinolite, anthophyllite, cummingtonite, glaucophane, grünerite, hornblende, riebeckite** and **tremolite.** Amphibole was so named by Haüy from the Greek word, meaning doubtful, because of the many varieties of this mineral. (E.S.C.S.)

AMPHIBOLITE. The amphibolites form a large group of rather important rocks of **metamorphic** char-

acter. As the name implies they are made up very largely of minerals of the amphibole group. There may be also a variety of other minerals present, such as **quartz**, **feldspar**, **biotite**, **muscovite**, **garnet**, or **chlorite** in greater or less amounts.

Depending upon the particular amphibole present these rocks may be light to dark green or black, the amphibole usually being in long slender prisms or laths, often quite coarse, sometimes in acicular or fibrous forms.

Because the mineral constituents are arranged parallel to the schistosity, amphibolites may have a strongly developed cleavage.

The occurrence of amphibolites accompanying gneisses, schists, and other metamorphic rocks of probable sedimentary origin strongly suggests a similar derivation. Yet some amphibolites cut other metamorphic rocks in the manner of dikes or sills. It is very likely that they have been derived from both original igneous and sedimentary rocks. Large masses of amphibolite suggest **gabbroic** stocks. Well known areas in which amphibolites are found are New England, New York State, Canada, Scotland, and the Alps. (E.S.C.S.)

AMPHILINIDEA. An order of **tapeworms** parasitic in fishes. (A.W.L.)

AMPHINEURA. The chitons and allied forms, a class of the phylum **Mollusca**. The more familiar members are flattened marine animals of oval outline. They have a shell composed of a series of separate plates, sometimes concealed within the body. The foot makes up most of the ventral surface and the limited **mantle** extends down about it to form a shallow groove. Nerve cells are in many cases distributed through the nerve cords so that the nervous system contains no ganglia (see **Ganglion**).

The class contains two orders:

Order **Aplacophora** (Solenogastres). Worm-like animals, somewhat cylindrical and elongate. Shell lacking.

Order **Polyplacophora.** The chitons. Flattened and oval, with shell plates. They are widely distributed, chiefly in the shallow waters. Sometimes used as food. (A.W.L.)

AMPHIOXUS. Commonly used to designate any of the primitive **chordates** called lancelets but more accurately a genus of these animals. **Cephalochordata.** (A.W.L.)

AMPHIPODA. An order of **crustaceans** including marine and fresh-water species. The beach-fleas are among the few which have a common name. (A.W.L.)

AMPHISBAENA. Reptilia, Lacertilia. The typical genus of a family of **lizards** which are snake-like because of the absence of legs. (A.W.L.)

AMPHOTERIC HYDROXIDES. These are hydroxides which can act as either **bases** or **acids**, e.g., **aluminum** hydroxide, **zinc** hydroxide, etc. (R.K.S.)

AMPLIFICATION FACTOR. This is a commonly used parameter in vacuum-tube work and is usually denoted by μ. In the conventional **tube** the current is controlled both by the voltage applied to the **grid** and that applied to the **plate**. Because the grid is closer to the **cathode** from which the **electrons** are drawn, a voltage applied to it is more effective in drawing the electrons across the tube than would be the same voltage applied to the plate (it is the passage of these electrons across the cathode-anode space which constitutes the tube current). Amplification factor is a measure of the relative effectiveness of voltages on the two electrodes and is defined as the negative of the ratio of the infinitesimal plate voltage change necessary to counteract a given infinitesimal change in grid voltage in order to keep the plate current constant.

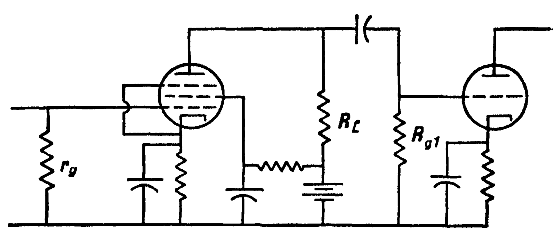
$$\mu = -dE_p/dE_g, I_p \text{ constant}$$

where dE_p and dE_g represent very small increments of plate and grid voltages. (L.R.Q.)

AMPLIFIER. An amplifier is a device for increasing the magnitude of some quantity and as normally used in electrical engineering applies to a vacuum **tube** and its associated circuit arranged to reproduce in its plate circuit in greater magnitude a voltage or current which is applied in its grid circuit. The term amplifier is used to denote both a single stage or several stages in cascade. Amplifiers are classified in various ways according to their use, circuit, etc., but all types depend upon a few basic circuits. Thus they may be termed current amplifiers or voltage amplifiers, power amplifiers, audio-frequency amplifiers, radio-frequency amplifiers and various coupling types.

Current amplifiers are designed to give an amplified current in the plate circuit. However, since the vacuum tube is a voltage-controlled device, the input current is applied to the grid as a voltage drop that is produced in an impedance. This voltage drop controls the current in the plate circuit which is designed to give relatively large currents. Voltage amplifiers on the other hand have their plate circuits designed to produce large voltage drops.

In any vacuum tube amplifier circuit the fundamental operation is the controlling of the plate current by a voltage applied to the grid. This plate-current change is utilized in various ways, giving rise to several standard classifications of voltage amplifiers. Reference to the figures will aid in understanding the operation. Fig. 1*a* shows a simple resistance-coupled circuit. The a-c voltage to be amplified is applied across the grid re-



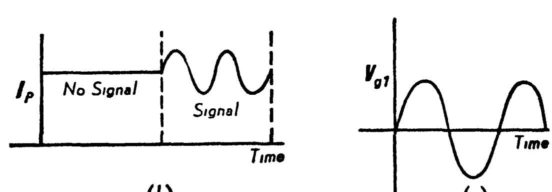


Fig. 1. Resistance-coupled amplifier.

sistor r_g. This voltage alters the plate current which varies as the grid voltage varies. For no-signal voltage on the grid plate current is a constant value of d.c., but the a-c voltage on the grid causes this to vary as shown in Fig. 1*b*. This current produces a potential drop across the plate resistor R_L which has the same form as the current. This voltage is applied across the grid resistor of the following tube through the coupling **condenser**. However, since a condenser circuit responds only to varying voltages only the a-c component will appear across the resistor R_{g1} as shown in Fig. 1*c*. With proper choice of circuit components the voltage on the second grid is several times that impressed on the first grid. The ratio of these voltages is the gain or amplification of the stage.

While this gain varies with frequency, for the middle portion of the operating range it is given by:

$$A = \mu R'_L/(R'_L + R_p)$$

where R_p is the dynamic plate resistance of the tube, μ is the **amplification factor** of the tube, and R'_L is R_L and R_{gl} in parallel. **Pentode** tubes are normally used for resistance-coupled amplifiers because of their much greater gain.

Fig. 2 shows another method, transformer-coupled, of utilizing the current change in the plate circuit. Here

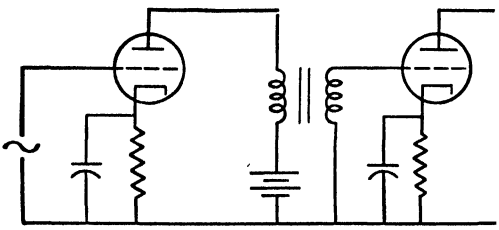

Fig. 2. Transformer-coupled amplifier.

the varying plate current produced by the alternating voltage on the grid produces a voltage across the secondary of the **transformer.** Since the transformer operates only on a c. the voltage across the secondary is a reproduction of that applied to the grid of the first tube. The gain of such a stage is very closely given for the middle of its operating range by:

$$A = \mu n$$

where n is the turns ratio of the transformer (secondary/primary) and μ is the amplification factor of the tube. Because they give a wider frequency range with transformers than other types of tubes, **triodes** are normally used in such circuits. Fig. 3 shows a third

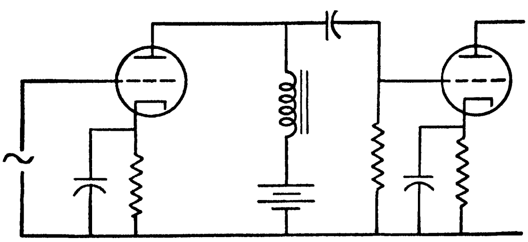

Fig. 3. Impedance-coupled amplifier.

method of coupling a voltage amplifier. This is very similar to the resistance-coupled case but the output voltage drop is across a **choke** or impedance coil. This is an impedance-coupled amplifier. Since the choke causes only a small voltage drop for d c. very little of the supply voltage is lost and most of it appears at the plate of the tube, thereby increasing the gain by decreasing the dynamic plate resistance of the tube. The frequency response characteristic of this amplifier is usually not as good as for the resistance-coupled type. The gain in the middle range is given by:

$$A = \frac{\mu 2\pi f L}{\sqrt{R_p^2 + (2\pi f L)^2}}$$

where f is the frequency and L is the inductance of the choke in henries. Other symbols are as before.

The three circuits shown are commonly used in audio-frequency amplifiers which must operate over a wide frequency range. For radio-frequency use the range is much more restricted in terms of its proportion of the mid-frequency value. As a consequence such amplifiers can and ordinarily do use tuned circuits for coupling elements. Such an amplifier is shown in Fig. 4. While there are many variations of the tuned amplifier this is typical of those used in the radio-frequency portion of the usual radio receiver. The response of a tuned amplifier varies markedly with frequency and the frequency at which the response is a maximum may be

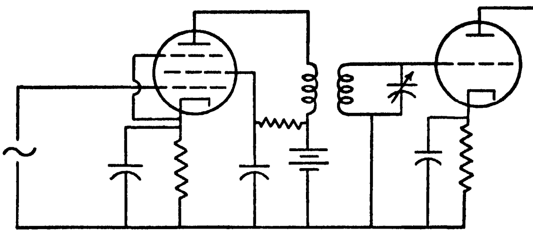

Fig. 4. Tuned amplifier.

adjusted by varying the condenser. This type amplifier, then, serves as a selective device to differentiate between stations and at the same time serves as an amplifier. The condenser shown is the tuning condenser controlled by the dial on the panel of the ordinary radio set.

For amplifying d-c voltages a direct-coupled amplifier must be used since the circuits shown before respond only to alternating voltages. Such an amplifier is shown in Fig. 5. It will be noted that the high voltage

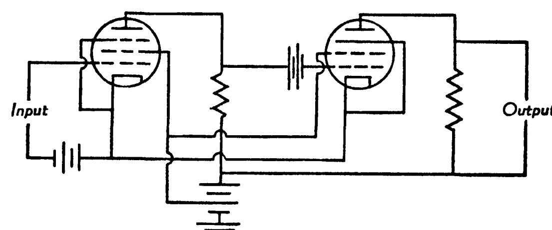

Fig. 5. Direct coupled amplifier for d.c.

of the plate of the first tube would be applied to the grid of the second if it were not for the bucking action of the grid or C battery which must, therefore, be made large enough to give the correct net voltage on the grid. Unless the A, B, and C voltages are carefully regulated, direct-coupled amplifiers are rather unstable and are to be avoided except in cases where nothing else will serve satisfactorily.

The amplifiers discussed above are intended primarily for voltage amplification. However, in many applications it is necessary to get power from an amplifier unit so at least the final stage is usually adjusted to give power rather than voltage output. An amplifier so adjusted is called a power amplifier. In radio transmitting circuits or large power audio-amplifiers several stages may be power amplifiers. For this type of service the circuit is adjusted to give as large a current as possible through the load, which has much lower resistance than in voltage amplifiers. The tubes used are somewhat larger as a rule than those of voltage circuits and are specially designed for large current outputs. Power amplifiers are frequently classified as Class A, B, AB or C, depending upon just how they are operated. Class A amplifiers operate about a mean grid bias value such that the output wave is essentially the same as the input wave and the d-c plate current has a constant value (the voltage amplifiers are Class A). A Class B amplifier has the grid bias adjusted so that plate current flows only on the positive half-cycle of the input signal. Class AB is intermediate between A and B. In these three classes a subscript 1 is often used to denote that the grid does not take current, and a subscript 2 to denote that grid current flows. Since AB and B amplifiers using single tubes do not give output waves similar to the input waves they must be operated **push-pull** for audio-frequency work. Class C amplifiers are adjusted so plate current flows for less than a half-cycle of the

input signal. They are used exclusively for radio-frequency work where a tuned circuit may be used for the load. (See **Tank Circuit.**) Fig. 6 indicates the rela-

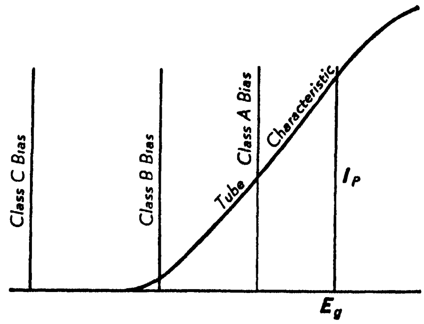

Fig. 6. Bias adjustments for various amplifier classes.

tive bias values for the different types of service. The efficiency becomes better but the distortion worse in the order A, AB, B and C. For audio-frequency work the power amplifiers are normally connected to the load (loud-**speaker**) through a transformer, while in radio-frequency work air-cored transformers and capacitance coupling are common.

Amplifiers have a wide variety of applications. In the ordinary radio **receiver** there are usually several stages of tuned amplifiers handling the high-frequency signal before **detection**, then one or more audio-voltage amplifiers, resistance- or transformer-coupled, and a power amplifier to drive the loud speaker. Phonograph and public address systems are other applications of audio amplifiers. Various industrial applications use all types. The radio broadcast station uses a wide variety—audio-voltage amplifiers in the studio, audio-voltage and power (ordinarily Class B) amplifiers at the transmitter, and usually several stages of Class C or C and B tuned amplifiers in the radio-frequency part of the transmitter. (L.R.Q.)

AMPUL or **AMPOULE.** A small sealed glass container for **drugs** that are to be given hypodermically. As they are completely sealed, the contents are kept in their original sterile condition. (R.S.M.)

AMPULLA. Any flask-like dilatation, such as the small saccular outgrowth of the water vascular system of starfishes, at the inner end of the tube foot, or the dilated portion of the semicircular canals of the vertebrate **ear.** (A.W.L.)

AMPULLIFORM GLANDS. Silk glands of **spiders** which produce the radial lines of the web. (A.W.L.)

AMPUTATION. This term is applied to the severance of a limb or other portion of the body. It may be traumatic or therapeutic. Congenital amputation is the removal of a part of the fetus in utero by a constricting band. (D.M.H.)

AMYGDALE. Amygdaloid.

AMYGDALIN. Glucosides.

AMYGDALOID. A vesicular rock, commonly a **lava,** whose cavities have become filled with a secondary deposit of mineral material such as **quartz, calcite, zeolites,** etc. The term is derived from the Greek word meaning almond in reference to the frequent almond-like appearance of the filled vesicles which are called amygdales or amygdules. (E.S.C.S.)

AMYGDULE. Amygdaloid.

ANABATIC WIND. A wind blowing uphill. In general, anabatic winds refer to winds originating in connection with surface heating, such as a breeze blowing up a valley when the sun warms the ground. (P.E.K.)

ANABOLISM. Metabolism.

ANACLINAL. Used in structural geology to define a direction opposite to the **dip of the strata** or formations. (R.M.F.)

ANACONDA. Reptilia, Serpentes. A giant **snake,** *Eunectes murinus,* of northern South America, related to the pythons and boas. It attains a length of 30′ or more and is said occasionally to attack human beings. The species occurs in tropical forests and spends much of its life in the water. (A.W.L.)

ANAEROBE. Any micro-organism that does not require free **oxygen** or air for growth. Among such organisms are the **tetanus**-bacillus, certain forms of **Streptococci,** the organisms of **gas gangrene,** etc. A facultative anaerobe is a micro-organism which usually lives in air or oxygen, but which can, if necessary, live without it. (R.S.M.)

ANAEROBIC BACTERIA. Anaerobe.

ANAESTHESIA (ANESTHESIA). Loss of sensation or feeling in a part or a whole of the body. This occurs with interruption of sensory impulses of any portion of a nerve or the nerve pathways in the **spinal cord, brain,** or the centers in the brain. It can occur as the result of injury or severance, infection, circulatory disturbances, in or about nervous tissue. Any **drug** that depresses or inhibits nerve impulses, or **tumor** formation near or in nervous tissue may produce anaesthesia. Anaesthesia may or may not be accompanied by motor **paralysis,** depending on whether or not the motor pathways are involved.

Block anaesthesia is the blocking of nerve impulses to a part of the body by injection of a drug into or near the nerve supplying that portion of the body.

Local anaesthesia refers to anaesthesia confined to a certain portion of the body. This is produced by the injection of a drug (novocaine or similar substance) in and about that area. This may also be done in very small areas by freezing, as with an ethyl chloride spray.

Spinal anaesthesia is produced by the injection of novocaine or related drugs into the spinal fluid in the lower back region. By this method anaesthesia of the trunk and lower limbs may be obtained while the patient retains full consciousness. The level of anaesthesia (lower and upper abdomen and lower chest) may be regulated by the amount of drug, amount of injected fluid and position of the patient. There are certain cases in which spinal anaesthesia is indicated, although it is not used as frequently as inhalation anaesthesia.

Intravenous anaesthesia is a process in which certain drugs may be injected into the blood stream to produce anaesthesia for short periods. Such drugs as barbituric acid derivatives, for example, sodium amytal, "evipal," pentothal sodium, etc., may be given intravenously.

Basal anaesthesia is a very light anaesthesia that is produced by drugs given by mouth, by rectum, or by injection, which requires added inhalation anaesthesia but in much lighter concentration than if the preliminary medication had not been given. Avertin and other narcotic and sedative drugs are used for this purpose. The process known as twilight sleep falls in this category. An advantage of basal anaesthesia is the fact that the patient need not see the operating room, as the basal anaesthetic is given in his room.

General surgical anaesthesia refers to anaesthesia of the entire body accompanied by loss of consciousness and involving paralysis of all vital functions of the body

except those governed by the respiratory and circulatory centers.

The anaesthetic agents most commonly used are as follows:

1. *Chloroform.* At present, chloroform is not commonly used in this country for anaesthesia. It is likely to cause ventricular fibrillation, a disturbance in heart rhythm which is fatal, and after prolonged or repeated use changes in the liver and kidneys may occur. It is contraindicated for children, for long operations, in patients who have diabetes, kidney, or liver disease and in general, when safer anaesthetics are available. Its anaesthetic qualities were first pointed out in 1847 by Flournes and by James Simpson.

2. *Diethyl Ether.* In non-expert hands diethyl ether is the safest of all anaesthetics. There are certain disagreeable after-effects following its use in any great quantity, such as nausea, vomiting and headache. It may be given by the open-drop method or through a closed machine in which it is mixed with oxygen or with nitrous oxide, ethylene, or cyclopropane. It also can be given by rectum, the diethyl ether being mixed with a bland oil. Diethyl ether (which is commonly referred to by the group name, that is, simply as "ether") was discovered in 1540 but it was over 300 years before it was used as an anaesthetic in surgery. Henry Hickman of England first made successful experiments with anaesthesia by inhalation in 1820, but no one was impressed with his discoveries. Crawford W. Long first used ether intelligently in 1842, but did not publicize its use until after Morton and Jackson claimed priority. William Morton, at the suggestion of Charles Jackson, a chemist, experimented with ether as an anaesthetic agent and in 1846 demonstrated it before the staff and students of the Harvard Medical School in the Massachusetts General Hospital. All modern methods date from this public demonstration. Of all anaesthetic agents, ether is the most commonly used. It should not be given in the presence of lung diseases.

3. *Nitrous Oxide* (*Laughing Gas*). This gas is the oldest of the inhalation anaesthetics. It has a rapid but weak anaesthetic effect and produces surgical anaesthesia only by asphyxia. It is therefore not used alone, but in combination with ether and oxygen, or with a basal anaesthetic such as avertin. If nitrous oxide were more potent it would be the perfect general anaesthetic since it is non-irritating and has no untoward side-effects.

4. *Cyclopropane.* This gas has been used as an anaesthetic since 1931. Its chief advantage lies in its effectiveness at a low concentration which permits its use with much higher concentrations of oxygen than can be given with ether, etc. It is therefore of special value in obstetrics and chest surgery. Although explosive, in the hands of an expert it is a safe and comparatively pleasant anaesthetic.

6. *Ethyl Chloride.* This is an inflammable liquid which vaporizes when sprayed on a mask. It is used for brief, light anaesthesia for minor procedures and as a preliminary agent to put a patient to sleep before giving him ether. Its use alone is not as safe as other anaesthetic agents. It is also used for local anaesthesia, being sprayed directly on the skin.

7. *Avertin* (*Tribromethylalcohol*). Avertin is a fluid preparation which, when given by rectum, produces a light anaesthesia. For surgical procedures of any degree, it must be supplemented by inhalation agents. Avertin, given first, reduces the amount of inhalation anaesthetics necessary to produce surgical anaesthesia. It also removes the element of fear before an operation since it is given while the patient is in his room in bed, and he usually arrives in the operating room sound asleep. (D.M.H.)

ANAL FEELERS. Posterior sensory appendages such as the anal cirri of **annelid** worms and the **cerci** of insects. (A.W.L.)

ANALCIME. **Analcite.**

ANALCITE. Analcite, sometimes called analcime, is a common **zeolite** mineral, a hydrous **soda-aluminum silicate.** It crystallizes in the **isometric** system, hardness, 5–5.5; specific gravity, 2.2; vitreous luster; colorless to white; but may be grayish, greenish, yellowish or reddish. It resembles **garnet** but is softer, and is distinguished from **leucite** only by chemical tests.

There are many excellent European localities. In the United States at Bergen Hill and West Paterson, N. J.; Keweenaw County, Mich.; and Jefferson County, Colorado. Nova Scotia furnishes beautiful specimens.

Analcite is a relatively common mineral and occurs with other zeolites in cavities and fissures in basic **igneous** rocks, occasionally in **granites** or **gneisses.** It seems to occur as a replacement and perhaps in some cases as a primary mineral crystallizing from a **magma** rich in soda and water vapor under pressure. The name analcite is derived from the Greek word meaning weak, in reference to the weak **electric charge** developed when heated or subjected to friction. (E.S.C.S.)

ANALOGY. **Homology.**

ANALYSIS OF COVARIANCE. **Analysis of Variance.**

ANALYSIS OF VARIANCE. The analysis of variance is a technique by which the sources of variation affecting a variable may be segregated and analyzed. It was introduced by R. A. Fisher in 1923. The method is of great importance in agriculture, biology, and industry. In all problems where the samples arise from normal populations having the same **variance,** the analysis of variance provides an effective and powerful technique. The analysis of variance is needed in the study of **randomized blocks** and in **Latin squares.** The analysis of **covariance** extends the analysis of variance to the problem of analyzing the sum of products into component parts. (L.A.A.)

ANALYTIC FUNCTIONS OF A COMPLEX VARIABLE. A complex variable w is said to be a **function** of a complex variable z when to each value of z in a certain region there corresponds a value of w. The function may be single-valued or multiple-valued.

At a given point of a region let Δz be an increment of the variable z and let Δw be the corresponding increment of a function $w = f(z)$, and form the ratio $\Delta w/\Delta z$. If this increment ratio $\Delta w/\Delta z$ approaches a unique limit when $\Delta z \rightarrow 0$, which is independent of the way in which $\Delta z \rightarrow 0$, then the function $f(z)$ is said to be differentiable at the point, and the limit is denoted by $f'(z)$ or dw/dz and is called the **derivative** of w.

An analytic function of a complex variable, $w = f(z)$, is a function which is differentiable everywhere in a certain region with the possible exception of a finite number of points, called singular points.

In order that a variable $w = u + iv$ may be an analytic function of the complex variable $z = x + iy$, it is necessary and sufficient that the following conditions,

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}, \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x},$$

called the Cauchy-Riemann differential equations, are satisfied.

If the function $w = u + iv$ is an analytic function of the variable $z = x + iy$, then both the real and imaginary parts u and v will satisfy **Laplace's equation:**

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0, \quad \frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} = 0.$$

Two such functions u and v are called conjugate functions. (L.L.S.)

ANALYTIC GEOMETRY. Analytic geometry is essentially the study of geometric problems by use of algebraic (analytic) methods.

Elementary **geometry** had its beginnings with the ancient Greeks and most of its propositions were discovered by them. The first systematic treatment of this subject which we have was written by Euclid about 300 B.C.; our present geometry textbooks are merely modifications of this great work of Euclid. This development of geometry was attained by use of purely geometric methods and with almost no use of algebraic methods. Indeed, **algebra** was practically unknown to the ancient Greeks.

Elementary algebra originated among the ancient Hindus and was later developed further by the Arabs of the earlier Middle Ages. The stage of development indicated by our present elementary textbooks of algebra was not reached historically until after the close of the Middle Ages. Thus, elementary geometry and algebra developed historically as two separate branches of mathematics.

The development of elementary geometry made little progress beyond the stage of the ancient Greeks until the 17th century, when algebra was first applied systematically to the treatment of geometric questions. In 1637 the French mathematician and philosopher René Descartes published his great work *"La Géométrie,"* in which he showed how algebraic methods could be applied to the study of geometry. He thus became the recognized founder of analytical geometry. Almost simultaneously, another Frenchman, Pierre Fermat, also discovered the idea of applying algebra to geometry systematically, but his work was not published and recognized until much later.

While analytical geometry deals with a much more extensive subject matter than does elementary geometry, its especial value lies in its new method, by which geometric properties of figures are treated systematically by means of algebraic methods.

The methods of solution of problems and proofs of theorems in elementary geometry involve a great many special and ingenious devices, and no general and uniform procedure is apparent. Analytical geometry, however, furnishes simple, general procedures for the solution of problems, which greatly simplifies the study of geometry. These new methods also enable us to solve in a simple manner many problems of geometry not considered by the ancient Greeks or problems very difficult of solution by the methods of elementary geometry. Thus, analytical geometry gives a new powerful tool for the study of old and new problems of geometry.

The essence of the new method of analytical geometry lies in its representation of points by sets of numbers and its representation of geometric figures by algebraic equations.

Some idea of the subject matter usually treated in Analytic Geometry may be gained by consulting the following topics: **Rectangular Coordinates, Polar Coordinates, Locus of an Equation, Equation of a Locus, Curves in a Plane, Graph of a Function, Slope of a Line, Straight Line in a Plane, Circle, Conic Sections, Ellipse, Parabola, Hyperbola, Higher Plane Curves, Parametric Equations, Trigonometric Curves, Exponential Curve, Empirical Equations, Transformation of Coordinates, Plane, Straight Line in Space, Surfaces, Sphere, Quadric Surfaces, Curves in Space.** (L.L.S.)

ANALYTICAL CHEMISTRY. Analytical chemistry is that branch of the science of chemistry which deals **with the detection or identification of a substance or** a part of the same, either element or radical, by qualitative tests and the estimation of the same by quantitative tests. The difficulties encountered are in part caused by the chemical inertness of a given unknown substance itself, and in part to the other substances that may accompany a given unknown material. It is comparatively easy to analyze **air** for **oxygen,** qualitatively by heating **copper** or **iron** metal in air and observing the formation of copper or iron oxide on the surface of the metal, and quantitatively by subjecting an isolated measured volume of air to an oxygen-absorbent, such as a **cuprous** salt solution in **hydrochloric acid** or **ammonium** hydroxide, or **sodium** pyrogallate solution, and measuring the non-oxygen residue.

The reaction with or resistance to action of various selected reagents serves to indicate whether an unknown substance is or is not a known substance. Analytical chemistry, therefore, demands the knowledge of a vast range of reactions of individual substances, the ability to apply this knowledge in systematic sequence, and the experience to make correct observations and deductions.

Quantitative analysis may be said to be applied qualitative analysis, since the methods used in the quantitative estimation of a substance depend largely upon the accompanying substances. Furthermore, a good qualitative analysis should furnish evidence of the quantitative order of magnitude of each substance present.

Methods of treating an unknown substance, in order to establish its identity, are known as dry or wet. Dry methods involve the heat treatment at various temperatures either alone or with various reagents. Assay methods for some metals, e.g., **silver, gold,** and many organic methods are of this type. Wet methods involve first the problem of getting the substance into solution by some reasonable treatment, or its proved resistance to this treatment. Such simple and apparently inconsequential matters as the size of the particles of a substance tested or the time allowed for treatment may determine the correctness or incorrectness of a given test. The technique demands ability to attend to details.

In the detection, identification and estimation of substances methods must be invented to cope with gases, liquids, solids, with active and inactive, and with similar and dissimilar substances. The greater the differences in chemical behavior, the easier it is in general to accomplish the analytical purpose. The principles of procedure involve:

Solubility of substances in water:

Reactivity of substances (a) With acids. (b) With bases. (c) With certain salts. (d) With certain other chemicals.	(1) In water as a medium, (2) By the application of high temperature or electricity.

General, group, and specific (individual) tests:

Much information can be gained by such simple preliminary examinations as those concerned with (a) color, ordinary and if solid of the fine powder, (b) odor, (c) general and detailed appearance of the specimen, (d) hardness, if solid, (e) density, (f) approximate solubility, in water, (g) behavior on heating *without* free access of air (as in a test tube): melting, boiling, sublimation, transition, decomposition point, if any.

The accepted system of qualitative analysis in which 23 metals are separated and identified in *solution* of their **nitrates** well illustrates the principles under discussion. Arranging these in the order of group separation, the reaction serving to separate the group is stated.

In the case of Group II, a sub-group treatment with yellow ammonium sulfide (ammonium sulfide containing dissolved sulfur) is used to dissolve **arsenic, antimony** and **tin** sulfides. Followed by filtration.

Analytical Group Number	Metals of the Group	Precipitate	Reaction Used to Separate the Group
I.	Lead.......... Mercurous..... Silver	$PbCl_2$, white.. .... $HgCl$, white............... $AgCl$, white....... ...	Addition of hydrochloric acid to the cold solution resulting in the precipitation of these chlorides followed by filtration. The separation of lead is not complete.
II, A. II, B	Mercuric.... Lead... .. Bismuth.... Cupric... . Cadmium.... Arsenic........ Antimony.... Tin. ...	HgS, black......... .. PbS, black .... Bi_2S_3, black... ... CuS, black........ .... CdS, yellow .. .. As_2S_3, As_2S_5, yellow.... .... Sb_2S_3, Sb_2S_5, orange... ..... SnS, brown, SnS_2, yellow	Addition of hydrosulfuric acid to the properly acidified (0.25 normal hydrochloric acid) filtrate from Group I resulting in the precipitation of these sulfides. Followed by filtration.
III.	Iron.... .... .. Chromium..... Aluminum.. ..	$Fe(OH)_3$, red-brown....... $Cr(OH)_3$, green............. $Al(OH)_3$, white.............	Addition of ammonium hydroxide to the properly prepared filtrate from Group II, resulting in the precipitation of these hydroxides. Preparation involves removal of hydrogen sulfide by boiling, and the oxidation of ferrous to ferric. Followed by filtration.
IV.	Cobalt...... .. Nickel . . Manganese ... Zinc.	CoS, black .... NiS, black .... MnS, pink.. .... ZnS, white	Addition of ammonium sulfide to the filtrate from Group III, resulting in the precipitation of these sulfides. Followed by filtration.
V.	Barium...... Strontium . Calcium . ..	$BaCO_3$, white .... $SrCO_3$, white.... .. ... . $CaCO_3$, white.......	Addition of ammonium carbonate to the properly prepared filtrate, from Group IV, resulting in the precipitation of these carbonates. Preparation involves removal of ammonium salts by evaporation and dry heating. Followed by filtration.
VI.	Magnesium. . Sodium . . . Potassium . Ammonium...	....	Individual tests for these in properly prepared portions of the filtrate from Group V, except ammonium must be tested for in the original material.

The groups are separately treated for the final identification of the presence or absence of each member by the use of reactions whose effectiveness in separation and identification have been found satisfactory in each case.

The **anions** or the acid radicals of inorganic salts have been classified by Bunsen in 1878 in the following way:

Group I: Silver nitrate produces a precipitate insoluble in nitric acid while barium chloride produces no precipitate: chloride, bromide, iodide, cyanide, hypochlorite, ferrocyanide, ferricyanide, thiocyanide.

Group II: Silver nitrate produces a precipitate which is soluble in nitric acid while barium chloride produces no precipitate: sulfides, tellurides, selenides, nitrites, acetates, cyanates

Group III. Silver nitrate produces a white precipitate soluble in nitric acid and barium chloride also produces a precipitate soluble in nitric acid: sulfites, selenites, tellurites, phosphites, carbonates, oxalates, iodates, borates, molybdates, tartarates, citrates, metaphosphates and pyrophosphates.

Group IV: Silver nitrate produces a colored precipitate soluble in nitric acid and barium chloride also produces a precipitate soluble in nitric acid: orthophosphates, arsenates, arsenites, vanadates, thiosulfates, chromates and periodates.

Group V: Both silver nitrate and barium chloride produce no precipitate: nitrate, chlorate, perchlorate, persulfate and manganates.

Group VI: Silver nitrate produces no precipitate while barium chloride produces a precipitate insoluble in nitric acid: sulfates, fluorides, fluosilicates.

Group VII: Non-volatile acids which form precipitates with both silver nitrate and barium chloride. Both precipitates are insoluble in nitric acid; silicate, tungstinate and anions of some rare elements.

After identifying the group into which the anion falls recourse must be made to confirmatory tests which can be found under the corresponding acid. (R.K.S.)

ANAMNIA. Vertebrates which do not develop an **amnion** during embryonic life. The group includes the cyclostomes (see **Cyclostomata**), **fishes**, and **amphibians.** (A.W.L.)

ANAMORPHISM. A term proposed by Van Hise in 1904 to designate the deep-seated constructive processes of **metamorphism** by which new complex (metamorphic) minerals are formed from the pre-existing simpler minerals, as contrasted with the surface alteration of rocks due to **weathering** and **cementation,** termed katamorphism. (R.M.F.)

ANASARCA. Generalized **Edema.**

ANATASE. **Titanium Dioxide.** (See **Octahedrite.**)

ANATEXIS. A term proposed by Sederholm in 1907 for the supposed end-processes of deep-seated **metamorphism** resulting in the partial or complete remelting of a specific type of rock in situ. (R.M.F.)

ANATOMY. In zoology, the structure of the body; also the science embracing our knowledge of structure. The term is usually applied to gross structure while the minute structure is treated under **histology,** but the two fields are sometimes distinguished as gross anatomy and microscopic anatomy. Another aspect of anatomy is

morphology. While this term applies properly to all structure it is usually employed in connection with external anatomical features of importance in **taxonomy.**

The simplest animals (**Protozoa**) are made up of a single **cell**, hence their structure is essentially that of the cell. Parts which are developed for the performance of special functions are known as organelles. With the grouping of cells to form more complex bodies a division of labor becomes possible and cells are specialized to perform different functions for the benefit of the individual. In the **sponges** this association is loose and the cells preserve a greater range of independent action than in other complex animals. The body is organized about a central cavity and is perforated by canals through which currents of water pass, carrying food and oxygen to the cells of the interior.

Above the sponges the cells of the body are more closely coordinated and are found in aggregates of varying complexity. The simplest aggregate is an association of similar cells for the performance of a special function; such a structure is called a **tissue.** One or more tissues may also enter into the formation of structures called **organs** which also perform special tasks, based on the associated functions of the component cells and tissues. Thus the stomach digests food through the motion produced by its muscular tissue, the secretion by its glandular lining, and the coordination of all parts by its nervous structures.

The initial differentiation of the body in animals above the sponges is the formation of two or three **germ layers** from which the various tissues, organs, and systems are derived. At the maximum eleven systems appear: the **skeletal system** provides support, the **muscular system** produces motion, the **integumentary system** is a protective covering which also takes part in interchange with the environment, the **digestive system** receives food and prepares it for absorption, the **respiratory system** provides oxygen, the **excretory system** removes wastes, the sensory (**sense**) **organs** receive stimuli from the environment and from the body itself and with the **nervous system** provide for coordination of the entire body, the **endocrine system** (see **Hormone**) provides internal chemical coordination, the **circulatory system** distributes materials throughout the organism, and the reproductive system (see **Reproduction**) perpetuates the species. There is some overlapping of these functions in many animals.

A consideration of the anatomy of any animal involves all of the details of development of these basic structures and systems. The anatomy of **vertebrates**, and human anatomy in particular, has become an intricate subject because of its relation to medicine. Some of the details of the general subject will be found under the various systems, under the principal groups of animals, under appendages, and under special anatomical terms too numerous to be listed here. (A.W.L.)

ANCHOR ICE. **Ground Ice.**

ANCHOR RING. **Torus.**

ANCHOVY. Pisces, Teleostei. Any of numerous small sardine-like fishes (**Pisces**), related to the herrings, whose richly flavored flesh is esteemed as a hors d'oeuvre. Especially the common anchovy, *Engraulis encrasicholus*, of the Mediterranean and the east Atlantic. (A.W.L.)

ANDALUSITE. An **aluminum silicate** corresponding to the formula Al_2SiO_5, this mineral is usually found in **metamorphic** rocks with **sillimanite, kyanite, garnet,** and **tourmaline.** It crystallizes in the **orthorhombic system,** developing coarse prisms of approximately square cross-section, but may be massive or granular. It shows a distinct cleavage parallel to the prism; hardness, 7.5; specific gravity, 3.16–3.20; vitreous luster; colorless to white, gray, brown, greenish or reddish; streak, white; transparent to opaque.

This mineral is named for its original locality, Andalusia, Spain. A variety of andalusite, chiastolite, has carbonaceous impurities so oriented that they produce a cross or a tesselated figure at right angles to the prism. Chiastolite comes from the Greek word meaning a cross. Localities are the Urals, the Alps, the Tyrol, The Pyrenees, Australia and Brazil. In the United States at Standish, Maine; Sterling and Lancaster, Massachusetts; Delaware County, Pennsylvania; and Madera County, California.

When clear it is used as a gem, and it has also been used to manufacture porcelain for spark plugs. (E.S.C.S.)

ANDESINE. **Feldspar.**

ANDESITE. A term originally applied to a porphyritic **lava** from the Andes Mountains by Leopold Van Buch, in modern terminology andesite is an extrusive **igneous rock,** the surface equivalent of **diorite.** In other words, it is composed chiefly of **plagioclase,** corresponding in chemical composition to **oligoclase** or **andesine** together with **biotite, hornblende,** or **pyroxene** in varying quantities.

Andesites are of rather widespread occurrence, being found in the Rocky Mountains, California, Alaska, South America, and at many other foreign localities. (E.S.C.S.)

ANDRADITE. **Garnet.**

ANDROGENESIS. The development of an egg after the entry of the male germ cell without the participation of the egg nucleus. (See also **Merogany.**) (A.W.L.)

ANDROMEDA. (Map, page 380.) The brighter stars of this **constellation** make an almost straight line between the constellations of **Perseus** and **Pegasus.** The most famous feature of the constellation is the great **nebula.** This is the only **spiral** which is actually visible to the naked eye and may be distinguished as a faint blur against a moonless sky close to the faintest star in the constellation which appears on the map (page 380). This is the largest of the spirals and is distant from the earth about 800,000 **light years.**

The bright star in Andromeda closest on the map to Perseus was called Almach by the Arabs and is a **double star,** one of the most beautiful in the sky in a small telescope. One component is a brilliant orange and the other a striking emerald color. Careful examination in a large telescope shows the green component to be also a double star. (W.K.G.)

ANDROMEDES. Andromedes is an alternative name for the **Bielid meteor shower** which is observed the latter part of November. This alternative name comes from the fact that the **radiant point** is in the **constellation** of **Andromeda.** (W.K.G.)

ANEMIA. A state of deficiency of either the number of circulating red **blood** cells or the amount of **haemoglobin** in the red cells.

The common symptoms and signs of anemia are weakness, easy fatigability and pallor of the skin and **mucous membranes.** When the condition is due to acute blood loss from a large hemorrhage, **shock** may be the outstanding sign. Pernicious anemia is frequently accompanied by a yellow tint of the skin, a smooth, red, sore tongue, digestive disturbances, and neurological disorders —numbness, tingling of the hands and feet, and weakness and paralysis of the legs.

The chief causes of anemia are (1) iron deficiency and consequent insufficient heamoglobin production, (2) blood loss, either acute or chronic, (3) increased destruction of red cells, (4) decreased production of red cells due to depression of the bone marrow.

Iron deficiency is the commonest cause of anemia. It is usually on a nutritional basis, associated with insuffi-

cient ingestion of iron-containing foods. Faulty absorption of iron from the gastrointestinal tract may also result in insufficient supply of iron. Nutritional deficiency is apt to occur when the need for iron is large, as in infancy and childhood, and during pregnancy. When the iron stores are inadequate, blood-cell production is interfered with, so that there is a reduction in the number of cells as well as a reduction of the cell haemoglobin content. Chronic blood loss results in gradual depletion of iron from the body and hence an iron-deficiency anemia. Abnormal bleeding from the uterus, from **hemorrhoids**, and from gastric or duodenal ulcers, (**peptic ulcer**), are the common causes of this.

Acute blood loss may be due to hemorrhage from any organ or tissue. Trauma, perforated peptic ulcer or other intra-abdominal hemorrhage, **abortion**, childbirth, are frequent causes.

Hemolytic anemia is characterized by increased blood-cell destruction. It occurs in an hereditary, familial form in which there is an abnormal fragility of the red cells. Other types are associated with reactions to chemicals and drugs, and with certain infections. (See **Hemolytic Jaundice.**)

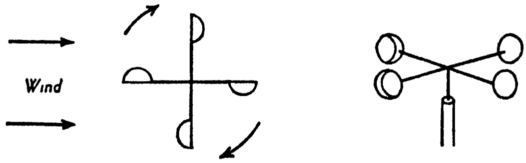
Decreased blood formation due to depression of the bone marrow occurs as a response to certain chemicals (benzene, arsphenamine), to x-ray treatment, and to diseases which mechanically interfere with the bone marrow, such as tumor masses which crowd out the blood cells.

The cause of pernicious anemia is unknown. The disease characteristically attacks blue-eyed, prematurely gray-haired individuals, usually in the 4th decade of life. Dietary factors and the lack of certain substances in the stomach and liver play a part in the disease. Treatment with liver extract produces a prompt remission. The patient must receive this therapy for the rest of his life or he will again become anemic.

Treatment of the various anemias is dependent on their type. The iron-deficiency anemias respond well to iron given orally. Correction of conditions causing chronic blood loss eliminate the attendant anemia. Hemorrhage often requires **transfusion.** Removal of the spleen is effective in the treatment of familial hemolytic anemia. (D.M.H.)

ANEMOGRAPH. **Meteorological Instruments.**

ANEMOMETER. One of a variety of instruments for measuring the velocity of the wind. The most common type resembles a windmill in principle, having either a fan-like vane wheel or, in the widely used "cup anemometer," a whirligig arrangement of four cup-like



Design of cup anemometer.

vanes, the speed of whose revolution about a vertical shaft is proportional to the wind velocity if the velocity is not too great. Another type utilizes the pressure due to the wind blowing against a vertical surface, as measured by the compression of a spring or by a tube connected with a pressure gauge. A modification of this type consists of a metal plate suspended by its upper edge and blown into an oblique position by the pressure of the wind. All such instruments must be experimentally calibrated. (See **Meteorological Instruments.**) (L.D.W.)

ANEMOSCOPE. **Meteorological Instruments.**

ANEMOTROPISM. Orientation of the body in relation to the wind. (A.W.L.)

ANEROID BAROMETER. **Meteorological Instruments.**

ANEURYSM. A sac formed by dilatation of the walls of an artery which communicates with the interior of the artery and is therefore filled with blood. This occurs most frequently in the wall of the arch of the aorta, as a late manifestation of syphilis. Aneurysm of the abdominal aorta is due to arteriosclerosis and consequent weakness of the vessel wall.

Arteriovenous aneurysm is the term used when there is an abnormal connection between an artery and a vein. (D.M.H.)

ANGEL-FISH. Pisces. A species, *Squatina squatina,* intermediate between the **sharks** and **rays.** Also applied to several tropical genera of bony fishes. (A.W.L.)

ANGINA PECTORIS. A symptom complex characterized by recurrent pain in the chest following physical exertion. The pain is usually in the region of the sternum and may radiate to the left arm. It may be mild or so severe that the patient feels he is about to die. It is usually of short duration. The precipitating exertion may be in the nature of climbing stairs, or eating a heavy meal, or it may be an emotional outburst.

The attacks are believed to be caused by **anoxemia** of the heart muscle, causing a cramp-like pain. Any disease process which causes narrowing of the lumen of the coronary arteries which supply the heart with blood may cause angina pectoris. The most frequent cause is **arteriosclerosis.** Marked **anemia** may also cause angina.

The syndrome occurs usually after 40, most frequently in the 50's. It is four times as common in men as in women. The disease is thought by some to be increasing, but the increase may be only apparent since the span of life is now longer and diseases of the older age-groups are now seen more frequently.

Angina pectoris does not cause death. Frequently an individual may have a number of anginal attacks and finally die in one which seems more severe than the others. In such a case he has died from **coronary occlusion** in which the lumen of the coronary artery is completely blocked, a portion of the heart is deprived of its blood supply and consequently dies. In angina pectoris the artery is not completely shut off and the cardiac anoxia is reversible.

Treatment of an attack consists of rest (usually the pain itself causes the individual to seek rest), nitrites, nitroglycerin, or nicotinic acid (**Vitamin B**). These drugs dilate the coronary vessels and may thereby give relief. Alcohol, as whiskey or brandy, may be of help by the same mechanism. Nitrites, animophylline and nicotinic acid may also be of use prophylactically. (D.M.H.)

ANGIOMA. A **tumor** which is composed mainly of **blood** vessels (hemangioma) or of **lymph** vessels (lymphangioma). (R.S.M.)

ANGIONEUROTIC EDEMA. This **allergic** disease is characterized by localized transient swelling of the skin or a mucous membrane of the body. The swelling may persist for a few hours or days. If the swelling occurs in the throat, death may occur by obstruction of the air passages. One form is inherited. Other forms are due to sensitivity to some **protein;** the disease is really a form of giant hives.

The swellings may be accompanied by prickling, itching, and burning sensations. The lips, skin about the eyes, hands, and feet are commonly involved. If the mucous membrane of the gastrointestinal tract is in-

volved in these localized swellings, severe abdominal pain with vomiting occurs and may simulate appendicitis, obstruction of the intestines, or some other abdominal accident.

Treatment is unsatisfactory as regards future attacks. **Adrenaline** by hypodermic aids during the acute attack. (D.M.H.)

ANGIOSPERMS. The angiosperms are **spermatophytes** in which the ovule matures to form a seed which is completely enclosed in an ovary, in contrast with the **gymnosperms,** spermatophytes which have the seed borne exposed on the surface of a scale. Angiosperms are more familiarly known as flowering plants, and the characteristic feature is the **flower.**

As a rule the angiosperms are land plants growing in a fixed position. A few of them have returned to the water as a habitat, but these are obviously reversions to an aqueous life and not primitive forms pointing the way along which angiosperms evolved. Tremendous diversity in size is found in this group; some of the so-called duckweeds are spherical masses of cells less than a millimeter in diameter; at the other end of the scale are the giant redwood trees (*Sequoia sempervirens*), many of which are over 300′ high. The variety of form shown in the angiosperms is nearly endless; each of the 130,000 and more species has a distinct appearance by which it can be distinguished. Some are tiny, herbaceous plants which live but a few weeks; others are giant trees living hundreds of years.

Included in the angiosperms are two types of plants. One, held to be the more primitive type, has a woody **stem** which has a much more complex structure than that found in the stems of Gymnosperms. The other has an herbaceous stem, a form of stem which dies to the ground at the end of the growing season. Herbaceous plants may live through to the next growing season by means of perennial roots and underground stems, or they may die completely, only the seeds surviving. This habit fits herbaceous plants especially to live in regions having growing seasons alternating with cold or dry periods. Herbaceous plants, or herbs, are most abundant in temperate and arctic regions.

The internal structure of angiosperm stems is much more specialized than that of gymnosperms. The xylem contains not only tracheids but also vessels and fibers. The vessels are open tubes of considerable length through which water is rapidly carried. The fibers give strength to the stem. In the **phloem** there are sieve tubes and companion cells, and also numerous fibers. The latter are often of great value to man. Linen, for example, is made from the phloem fibers of the flax plant. In the woody angiosperms and in many of the herbaceous forms there is a well developed **cambium.**

The leaves of angiosperms are of many shapes and sizes, but are typically thin and contain numerous veins. In the axils of each leaf there is a bud which may develop into a branch or a flower.

But all bear flowers at some time during their lives. The flower is the basis for classifying angiosperms. A flower is a special shoot or branch which is adapted to advance **pollination** and **fertilization.** Flowers may arise from the **axils** of ordinary leaves or may be found in the axils of special modified leaves called bracts. A flower consists essentially of two organs: stamens in which the pollen grains are formed, and pistils in which the ovules are found. In addition to these two essential organs, there are usually accessory structures, which collectively make up the perianth. These accessory structures include the calyx, composed of separate parts called sepals, and the corolla, composed of petals. The latter are usually bright-colored and are assumed to attract insects or other animals which effect **pollination.**

The mechanical transfer of pollen grains from the stamens to the pistil is known as pollination. In many flowers the wind is the agent effecting pollination; in others, insects, and in a few, water or other agents.

Having reached the pistil, the pollen grain germinates, forming a slender tube called the pollen tube, which grows down through the tissues of the pistil until it reaches the ovule. The latter is enclosed in one or two layers called the integuments, in which there is a minute hole called the micropyle. The pollen tube grows through this micropyle and into the embryo sac. The embryo sac is typically a 7-celled structure with rather definite characteristics. At the end farthest from the micropyle there are three small cells called antipodal cells which are of little importance. At the opposite end, nearest the micropyle, there are 2 cells, the synergids, and a third cell, the egg cell, which in many species is reduced to an egg nucleus. The remainder of the embryo sac is a large cell in the center of which there are 2 polar nuceli close together. These 2 nuclei soon unite, forming the fusion nucleus.

In angiosperms 2 male nuclei are discharged from the pollen tube into the embryo sac. One of these haploid nuclei unites with the egg nucleus, forming the diploid **zygote,** from which the **embryo** develops. The other nucleus unites with the fusion nucleus in the center of the embryo sac, forming the triploid endosperm nucleus. There are therefore two separate nuclear fusions in the embryo sac. This is characteristic in all angiosperms and is called double fertilization.

From the fertilized egg or zygote the embryo is formed. Usually this embyro is an elaborate body consisting of one or two seed leaves or cotyledons, a primitive root or hypocotyl and a primitive bud or epicotyl. Often the embyro is surrounded by a mass of nutritive material known as endosperm which develops from the endosperm nucleus. Surrounding this there are one or two seed coats, derived from the integuments. This whole structure is the **seed,** which is contained in the ripened ovary or **fruit.**

The angiosperms are separated into two large groups, the **dicotyledons** and the **monocotyledons.** The origin of the angiosperms is as yet unknown. They are known to have existed in the **Jurassic** period, but were not at all abundant until the **Cretaceous** period (see **Paleobotany**). The earliest **fossil** members of this group are well differentiated plants which give little indication as to their possible ancestry. Within the group, **evolution** seems to be from the woody type to the herbaceous, and from plants with flowers having an indefinite number of parts arranged in spiral manner and not fused. As evolution progressed the number of flower parts became reduced and definite and finally fused. In many cases great irregularity replaced the more primitive regularity. The angiosperms are the dominant land flora of the present day. (R M.W.)

ANGLE, DELAY. Ignition.

ANGLE, DIHEDRAL. Acute angle between a line perpendicular to the plane of symmetry and the projection of the wing axis on a plane perpendicular to the longitudinal axis of the airplane. If the wing axis is not approximately a straight line, the angle is measured from the projection of a line joining the intersection of the wing axis with the plane of symmetry and the aerodynamic center of the halfwing on either side of the plane of symmetry.

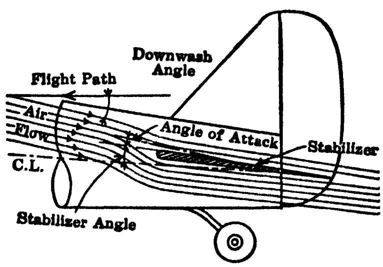
Most airplanes have some dihedral in the wings, it being necessary to use more dihedral where the lateral stability of the airplane depends primarily upon the stabilizing action of dihedral. Dihedral is most pronounced in the low-wing monoplane; least in the parasol monoplane. (F.T.M.)

ANGLE, DOWNWASH. Airfoil; Downwash.

ANGLE, PROPELLER BLADE. Propeller Blade Angle.

ANGLE, STABILIZER. This is, structurally, the acute angle between the plane of the stabilizer and the

longitudinal axis of an airplane. The attack angle of the stabilizer is aerodynamic in character and is defined as the acute angle between the plane of the stabilizer and the relative wind *at the tail.* It is seen in the accompanying figure that this involves the **downwash** from



the wings, and consequently a slight positive stabilizer angle might be a negative angle of attack.

The stabilizer angle is sometimes made adjustable within a 5–10° range to allow the pilot to "trim" the airplane in flight. (F.T.M.)

ANGLE, STALLING. **Burble.**

ANGLE OF ADVANCE. The degrees of crank angle traveled by the crankpin of an Otto (spark ignition) engine between ignition position and outer dead center. It represents a certain lead given to combustion, so that it may be nearly completed at the beginning of the power stroke. This helps to achieve the maximum possible **mean effective pressure.** Angle of advance needs to be greater the higher the rotative speed of the engine. It is seldom less than 10° (except during cranking) and may advance on some engines to 30° or 40° before dead center at maximum speed. (Compare with **Delay Angle** of the compression ignition engine. See **Ignition System.**) (F.T.M.)

ANGLE OF ATTACK. The angle of attack is the acute angle included between the direction assumed by the wind relative to an airfoil and some basic reference **chord** of the airfoil. There are two of these reference chords. The one employed for general and structural use is the geometric chord, the other, the zero-lift or aerodynamic chord. (F.T.M.)

ANGLE OF INCIDENCE. Acute angle between plane of the wing chord and the longitudinal axis of an airplane. The angle is positive when leading edge is higher than trailing edge. (F.T.M.)

ANGLE OF REPOSE. The angle of repose is the maximum angle with the horizontal at which loose material such as grain, sand, coal, or stone will retain its position without tending to slide. The moisture content and the distribution of the fine and coarse particles have a marked effect on the value of this angle. The angle of repose is an important factor in the design of **retaining walls,** earth **dams,** and embankments and is particularly valuable in the design of storage bins and **bunkers** since the allowable surcharge as well as the active horizontal pressure depends upon its value. Tables giving the approximate value of the angles of repose for various materials will be found in most Civil Engineering handbooks. (C.W.C.)

ANGLE-WING. Insecta, Lepidoptera. **Butterflies** of the genus *Polygonia.* Their wings are sharply angular but no more so than those of some other species. (A.W.L.)

ANGLER-FISH. Pisces, Teleostei. Bottom-feeding fishes (**Pisces**) of the family Lophiidae, named from the tufted tentacle on the head which is said to attract prey. A common species is *Lophius piscatorius.* (A.W.L.)

ANGLES. An angle is a fundamental mathematical concept, being one of the simple geometrical elements.

A plane angle is generated by the rotation in a plane of a half-line about a fixed point, called the vertex of the angle, from a position called the initial side of the angle to a final position called the terminal side of the angle. An angle generated by rotation in a counterclockwise sense is called positive, by clockwise rotation negative. Such an angle, in which a sense of rotation is distinguished, is called a directed angle, as shown by the two examples given (Figs. 1 and 2).

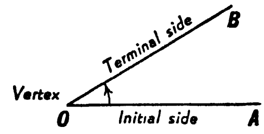


Fig. 1.

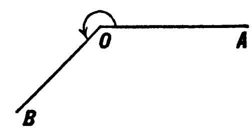

Fig. 2.

Co-terminal angles are angles which have the same initial and terminal sides. They differ in measure by a multiple of 4 right angles. The numerically smallest of a set of co-terminal angles is called the principal value of the set.

Complementary angles are angles whose sum is a right angle; supplementary angles are angles whose sum is 2 right angles.

Quadrantal angles are angles which are multiples of a right angle; if such an angle is placed with its vertex at the origin of a set of **rectangular coordinate** axes and its initial side along the positive X-axis (in so-called standard position), its terminal side will fall along one of the axes.

Besides plane angles, there are **dihedral angles** and **spherical angles.** (L.L.S.)

ANGLESITE. The mineral anglesite is naturally occurring **lead** sulfate, crystallizes in the **orthorhombic** system and may be found mixed with **galena,** from which it is usually formed by **oxidation.** Hardness, 3; specific gravity, 6.12–6.39; luster, adamantine to vitreous or resinous; transparent to opaque; streak, white; colorless to white or green but may be rarely yellow or blue.

It is used as a source of lead. There are many foreign localities, and in the United States it has been found in large crystals in the Wheatley Mine, Phoenixville, Pa.; also in Missouri, Utah, Arizona and Idaho.

It is named from Anglesey, England. (E.S.C.S.)

ÅNGSTRÖM. The angstrom, or angstrom unit, named for the pioneer spectroscopist Ångström, is the unit of length customarily used in expressing **wavelengths of light.** It is equal to 0.00000001 cm. or 10^{-10} meter, and is therefore sometimes called the "tenth-meter." The wavelength of sodium (yellow) light is about 5890 angstroms (A). The micron, or 0.001 mm., used for approximate designations of wavelength in the visible and infra-red, is 10,000 A. Both the angstrom and the micron are convenient also in expressing other very small lengths, such as the thickness of liquid films, etc. The unit above defined is the absolute angstrom. To obviate inconvenience due to variation of spectroscopic wavelengths with air pressure, another unit, the international angstrom, has been adopted, such that the wavelength of the red line of cadmium is exactly 6438 4696 of these units. The two units are equal only in a vacuum. (L.D.W.)

ANGUCLAST. **Phenoclast.**

ANGULAR ACCELERATION. **Angular Velocity and Angular Acceleration.**

ANGULAR MOMENTUM. The product of moment of inertia and angular velocity. The analogy between

concepts relating to translational motion and to rotation is emphasized by reference to both linear and angular velocity, acceleration, and momentum. For rotational motion, **angular velocity** takes the place of linear velocity and **moment of inertia** takes the place of mass. Hence the angular momentum of a body with respect to a given axis of rotation is defined as the product of its moment of inertia with respect to that axis by its angular velocity about that axis. It must be regarded as a **vector** quantity, whose magnitude is that of the product just stated and whose direction is that of the angular velocity, determined by the axis of rotation.

The principle of conservation applies to angular as well as to linear momentum. That is, no change of configuration within a system, uninfluenced by external forces, can alter the total angular momentum of the system. Thus, a slowly rotating swarm of particles, like a cloud of gas in space, if it contracts under its own gravitational attraction with attendant decrease in moment of inertia, must rotate the more rapidly to keep its angular momentum constant. Again, if a person, whirling about on tiptoe, with arms extended, suddenly brings the arms down to the sides, he will as suddenly begin to whirl faster, the effect being more pronounced if he holds heavy weights in his hands. Angular momentum being a vector quantity, the principle applies as well to its direction as to its magnitude. The result is that any rotating body tends to maintain the same axis of rotation; a fact well illustrated by the spinning top and by the stabilizers used on some ocean vessels. (L.D.W.)

ANGULAR PERSPECTIVE. Perspective.

ANGULAR UNCONFORMITY. Unconformity.

ANGULAR VELOCITY AND ANGULAR ACCELERATION. Quantities relating to rotational motion. While the use of the term "angular velocity" may be extended to any motion of a point with respect to any axis, it is commonly applied to cases of rotation. It is then the **vector**, whose magnitude is the time rate of change of the angle θ rotated through, i.e., $d\theta/dt$, and whose direction is arbitrarily defined as that direction of the rotation axis for which the rotation is clockwise. The usual symbol is ω or Ω.

Angular velocities, like linear velocities, are vectorially added; for example, if a top is spinning about an axis which is simultaneously being tipped over toward the table, the resultant angular velocity is the vector sum of the angular velocities of spin and of tipping. (This enters into the theory of **precession.**)

Angular acceleration is the time rate of change of the angular velocity, expressed by the vector derivative $d\omega/dt$. Only in case the direction of the axis remains unchanged can the angular velocity and angular acceleration be treated as scalars. The effect of torque applied to a body free to rotate about an axis is to give it angular acceleration, and the opposition offered by the body to this process gives rise to the concept of **moment of inertia.** (L.D.W.)

ANHARMONIC RATIO. If we have given four points A, B, C, D on a straight line, their anharmonic ratio (or cross-ratio) is defined as the ratio $\dfrac{AC}{AD}\Big/\dfrac{BC}{BD}$ in which the segments are to be regarded as positive or negative according to the order of the letters.

The anharmonic ratio of any four points z_1, z_2, z_3, z_4 in a complex plane is defined as the ratio

$$\frac{z_1 - z_3}{z_1 - z_4} : \frac{z_2 - z_3}{z_2 - z_4},$$

in which the z's are complex numbers representing the points. As a special case of this we have the definition of the anharmonic ratio of four given real numbers. There are in general six distinct anharmonic ratios obtained by rearranging the given numbers or points in order. (L.L.S.)

ANHEDRAL. Allotriomorphic.

ANHYDRITE. The mineral anhydrous **calcium** sulfate, $CaSO_4$, occurs in granular, scaly or fibrous masses, rarely crystallized in **orthorhombic** tabular or prismatic forms. Hardness 3–3.5; specific gravity 2.9–2.98; translucent to opaque; streak white; color may be white, gray, bluish or reddish. Anhydrite has three cleavages at right angles to one another. It is similar to **gypsum** and occurs under the same conditions often with the latter mineral. Anhydrite is usually found in **sedimentary** rocks associated with **limestones,** salt, and **gypsum,** into which it changes slowly by the absorption of water.

It is found in Poland, Saxony, Bavaria, Württemberg, Switzerland and France. In the United States in Niagara County, N. Y., West Paterson, N. J., and Nashville, Tenn. It occurs also in Nova Scotia and New Brunswick. (E.S.C.S.)

ANILIDES. Amines and Amides.

ANILINE. Aniline, phenylamine, aminobenzene ($C_6H_5NH_2$) is a colorless, odorous liquid, melting point −6° C., boiling point 184° C., slightly soluble in water, miscible in all proportions with alcohol or ether, poisonous, which turns yellow to brown in the air, is a weak base forming salts with acids, e.g., anilinehydrochloride ("aniline salt" $C_6H_5NH_2 \cdot HCl$) from which aniline is reformed by addition of **sodium** hydroxide solution. Aniline reacts (1) with **hypochlorite** solution, to form a transient violet coloration, (2) wth **nitrous acid** (a) warm, to form **nitrogen** gas plus phenol, (b) cold, to form **diazonium** salt (benzene diazonium chloride $C_6H_5\underset{\underset{N}{\vdots}}{N}—Cl$), (3) with **acetyl chloride, acetic anhydride,** or **acetic acid** glacial, to form N-phenylacetamide $\left(\text{acetanilide, "antifebrin" } C_6H_5N{<}^{H}_{OCCH_3}\right)$, (4) with **benzoyl chloride,** to form N-phenylbenzamide $\left(\text{benzanilide, } C_6H_5N{<}^{H}_{OCC_6H_5}\right)$, (5) with benzenesulfonyl chloride, to form N-phenylbenzene sulfonamide ($C_6H_5SO_2NHC_6H_5$), soluble in sodium hydroxide, (6) with **chloroform** ($CHCl_3$) plus alcohol plus sodium hydroxide, to form phenyl isocyanide (C_6H_5NC) very poisonous, (7) with **sulfuric acid** at 180° to 200° C., to form para-aminobenzene sulfonic acid (sulfanilic acid, $H_2N \cdot C_6H_4 \cdot SO_3H(1,4)$), (8) with **nitric acid,** when the amine group is protected, e.g., using acetanilide, to form mainly para-nitroacetanilide ($CH_3CONH \cdot C_6H_4 \cdot NO_2(1,4)$), from which para-nitroaniline ($H_2N \cdot C_6H_4 \cdot NO_2(1,4)$) is obtained by boiling with concentrated hydrochloric acid, (9) with **chlorine** in an anhydrous solvent, such as chloroform or acetic acid glacial, to form 2,4,6-trichloroaniline ($(1)H_2N \cdot C_6H_2Cl_3(2,4,6)$), (10) with **bromine** water, to form white solid 2,4,6-tribomoaniline ($(1)H_2N \cdot C_6H_2Br_3(2,4,6)$), (11) with **potassium** dichromate in sulfuric acid, to form aniline black dye, and, by further oxidation, benzoquinone ($O{:}C_6H_4{:}O(1,4)$), (12) with **potassium** permanganate in sodium hydroxide, to form azobenzene ($C_6H_5N{:}NC_6H_5$) along with some azoxybenzene ($C_6H_5NO{:}NC_6H_5$), (13) with reducing agents, to form aminohexahydrobenzene (cyclohexylamine, $H_2N \cdot C_6H_{11}$), (14) with alkyl halides or alcohols heated, to form alkyl anilines, e.g., methylaniline ($C_6H_5NHCH_3$), dimethylaniline ($C_6H_5N(CH_3)_2$).

Aniline may be made (1) by the reduction, with iron or tin in **hydrochloric acid,** of nitrobenzene, and (2) by the amination of chlorobenzene by heating with ammonia to a high temperature corresponding to a pressure of over 200 atmospheres in the presence of a catalyst (a mixture of cuprous chloride and oxide). **Aniline is** the end-point of reduction of most mononitrogen substi-

tuted benzene nuclei, as nitrosobenzene, beta-phenylhydroxylamine, azoxybenzene, azobenzene, hydrazobenzene. Aniline is detected by the violet coloration produced by a small amount of sodium hypochlorite.

Aniline is used (1) as a solvent, (2) in the preparation of compounds as illustrated above, (3) in the manufacture of dyes and their intermediates, (4) in the manufacture of medicinal chemicals. (See also **Amines and Amides.**) (R.K.S.)

ANIMAL ASSOCIATIONS. While most animals are solitary, associating with others of their kind only incidentally or during the breeding season, others normally live in some relationship with members of the same or of other species.

The simplest association of members of the same species is gregariousness. Gregarious animals are not bound by the association but profit by it. Examples are the great herds of herbivorous animals such as the bison and the packs of predacious animals, such as wolves.

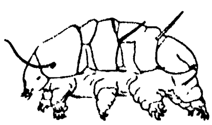
Colonial association may be accompanied by structural union between individuals, as in many marine polyps, or may be based on behavior, as in the social insects. The term merges with social organization. This type of association is accompanied by structural specialization of individuals for special tasks, except in human society where it depends on specialized training.

The association of individuals of different species may be the relatively loose type called commensalism in which both forms benefit but not in an essential way, or the indispensable symbiosis in which neither organism can persist without the other. An excellent example of symbiosis is the relation of **termites** with the **protozoa** found in their intestine; neither can live without the other.

An association in which one individual lives at the expense of the other is called **parasitism.**

Slavery is an association practiced by some of the social insects and by man; among the insects the slaves are of a different species.

Such relations as symbiosis and parasitism also occur among plants where they are exemplified by the combining of algae and fungi to form lichens and by the mistletoe, parasitic on trees. Symbiotic relations between animals and plants also occur. (A.W.L.)



Bear animalcule.

ANIMALCULE. A minute animal. Applied to the **protozoa** and to such microscopic forms as the **rotifers.** (A.W.L.)

ANIONS. Anions are negatively charged atoms or **radicals.** (See **Ions.**) (R.K.S.)

ANISE. *Pimpinella Anisum.* Umbelliferae. An herb of the Umbel family (see **Carrot Family**) having a strong odor and bearing seeds from which is distilled the aromatic substance, oil of anise. It is sometimes cultivated as a medicinal plant (see also **Volatile Oils**). (R.M.W.)

ANISOGAMY. **Heterogamy.**

ANISOLE. Methylphenyl ether. (See **Alcohols and Ethers.**)

ANKERITE. **Dolomite.**

ANKLE. The slender part of the lower leg at its articulation with the foot. (A.W.L.)

ANKYLOSIS. Loss of motion in a joint. This may be caused by a disease process in or around the joint, producing either stiffening of the surrounding muscles, or the laying down of bone in the joint itself. In other cases, fibrous tissue and adhesions may cause the loss of motion. Surgical ankylosis or arthrodesis is carried out as a treatment for certain diseases of joints, especially tuberculosis. (D.M.H.)

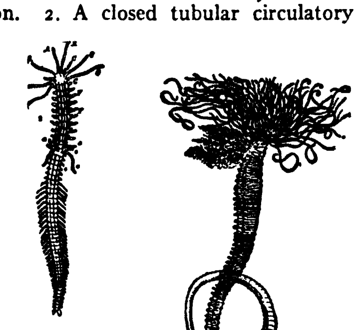
ANNABERGITE. The mineral Annabergite is a rather rare **nickel arsenate** with the formula $Ni_3As_2O_8 \cdot 8H_2O$ crystallizing in the **monoclinic** system. It is of secondary origin, resulting from the alteration of pre-existing nickel minerals. It has been found in Saxony, France, and Cobalt, Province of Ontario, Canada. It was named from Annaberg in Saxony. (E.S.C.S.)

ANNEALING. Heating and cooling of metals to soften or effect other changes in properties. Ductile metals which have been work-hardened by cold rolling, cold drawing, or by other forms of plastic deformation may be softened by process annealing. The temperature required is relatively low compared with full annealing and the cooling rate is not critical. Full annealing for maximum softness and ductility requires heating to higher temperatures and in some cases the cooling rate is important. Most steels, for example, have a critical transformation temperature range, and they must be cooled slowly through this range for full annealing. On the other hand, austenitic stainless steels have no such range and are annealed by heating to a very high temperature followed by a rapid cool, often by quenching in water. Silicon steel sheets for transformer cores, motor and generator laminations, etc., require slow cooling in annealing to avoid internal stresses which impair their electrical properties.

Normalizing is a special treatment applied to steels to refine the grain structure and remove effects of hot rolling or other previous treatments. Steels are generally normalized by heating to approximately 100° F. above their critical transformation range followed by cooling in still air. (See also **Heat Treating.**) (R.H.H.)

ANNELIDA. The segmented worms, including **earthworms** and **leeches.** This phylum is biologically interesting because it shows in a primitive form the structural plan of the more complex animals.

The annelids are characterized by: 1. Metameric segmentation. 2. A closed tubular circulatory system in most forms. 3. A coelom. 4. An excretory system with tubules opening from the **coelom** to the exterior in various segments. 5. The alimentary tract is tubular, with regions specialized for various functions. 6. The nervous system consists of a dorsal brain above the oesophagus connected by cords passing around the **oesophagus** with a ventral chain of ganglia (see **Ganglion**) below the alimentary tract. 7. **Setae** are present in many species.



1. 2.

1. A sexual individual of *Autolytus* with male about to detach. (*From Verrill, Invertebrate Animals of Vineyard Sound.*) 2. Tufted worm (*Amphitrite ornata*). (*Drawn by Verrill.*)

The annelids are classified as follows:

Class **Archiannelida.** Small marine annelids without setae; with few to many segments.

Class **Chaetopoda.** Worms with setae. No suckers. External segmentation distinct and metameric. **Earthworms** and many aquatic species.

Class **Gephyrea.** Large marine worms, not segmented when adult.

Class **Hirudinea.** Flattened worms without setae but with a sucker at each end of the body. External segmentation consisting of 2–14 annuli to each metamere. Mostly aquatic, a few marine and a few terrestrial. Mostly blood-sucking parasites. The **leeches.** (A.W.L.)

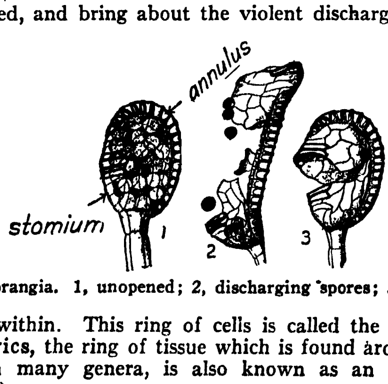
ANNUAL. A plant which normally completes its life cycle, from seed to seed, in a single growing season. Typical annuals are corn, wheat, cucumber, and nasturtium. Annual plants are especially suited for life in regions where the growing season is short and alternates with an unfavorable cold period or dry season. (R.M.W.)

ANNUAL RING. A layer of wood added to the **stem** in one growing season.

In temperate climates stem growth occurs during the warm spring and summer months. The cells formed in spring when active growth is taking place are characteristically large, while during the summer only smaller cells are added. This alternation of cells results in the formation of definite concentric rings readily seen in cross-sections of woody stems. Actually the growth increment is in the form of a sheath continuous over the entire stem except at the growing tips. External conditions may have a profound effect on the appearance of the annual ring; favorable growing seasons with ample moisture result in broad rings, while seasons of drought produce narrow rings. Removal of surrounding overshading trees may result in a pronounced increase in the thickness of the annual ring. At times events such as severe defoliation by insects or cases of drought may produce two rings in one season; such rings are ordinarily not sharply distinct as are normal ones, and are called false annual rings. Counting of annual rings gives an accurate index of the age of the tree, while attention to details such as variable thickness of successive rings serves to indicate environmental changes. By careful comparison of different logs, even though they be largely reduced to charcoal, one may determine the actual year in which the ring was formed. By this means it has proved possible to establish the probable age of many ruins in the south-western states. In tropical countries having a continuous growing season, annual rings are not formed or only slightly developed. If, however, alternating rainy and dry seasons occur, then they appear. (R.M.W.)

ANNULAR. Spur Gearing.

ANNULUS. In the **sporangium** of many **ferns,** there is a ring of cells which have their walls characteristically thickened, and bring about the violent discharge of the



Fern sporangia. 1, unopened; 2, discharging spores; 3, empty.

spores within. This ring of cells is called the annulus. In **agarics,** the ring of tissue which is found around the stalk in many genera, is also known as an annulus. (R.M.W.)

ANOA. Oxen.

ANODE. The anode (also frequently called the plate) is the principal electrode for collecting electrons in an electron **tube,** and is, therefore, connected to the positive side of the circuit. Anode also designates the positively charged electrode in an electrolytic cell. (See **Electrochemistry.**)

Since most of the electrons which flow across the space between the electrodes of a tube are eventually collected by the anode and usually they are traveling at high speed when they strike it, there is an appreciable amount of energy to be dissipated by the anode. This energy is the kinetic energy which the electrons have acquired in traversing the tube under the influence of the various voltages applied to the tube. The electrons are stopped upon striking the anode and the energy they possess goes into heating it. It is constructed to dissipate this heat more or less readily, typical constructions involving radiating fins, water jackets, or simply blackening the metal to make it radiate more efficiently. Even with these precautions in construction the anodes of some tubes will be hot enough to glow. (L.R.Q., R.K.S.)

ANODE RAYS. Among the positively charged particles recognizable in a (so-called) **vacuum tube,** and mixed with the ionized molecules and atoms of the rarefied gas, are sometimes found ions which are traceable to the metallic anode or to impurities in it or upon its surface. The anode may be oxidized or have films or patches of metallic salts upon it which, in the operation of the tube, in some manner not fully understood, yield ions of the metal. If the anode is treated with alkali or alkaline-earth salts or oxides and strongly heated, very copious positive emission may result, serving as a convenient source of positive rays. In some instances occluded hydrogen seems to supply the ions. The experimental study of these rays is hampered by the uncertainty of the supply, which depends upon impurities often of unknown nature and amount; it is also complicated by the presence of the positive ions of the residual gas. The subject is intimately related to positive thermionic emission. **(Thermionic Phenomena.)** (L.D.W.)

ANODYNE. Any medicine which relieves pain or discomfort. The best-known anodynes are **morphine, codeine, hyoscine, atropine, ether, aspirin** and "pyramidon" **(amidopyrine).** (R.S.M.)

ANOLIS. Reptilia, Sauria. The name of a genus of **lizards** adapted also as a common name. Small, mostly brightly colored lizards of the warmer latitudes of the Americas. The little lizard sometimes sold under the name chameleon is the Carolina anolis, *Anolis carolinensis,* a common species of the southern United States and southward. (A.W.L.)

ANOMALISTIC YEAR. Year.

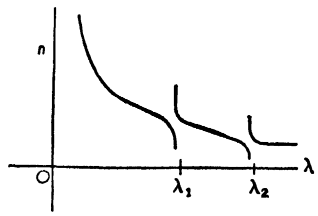
ANOMALODESMACEA. An order of **bivalve** mollusks, mostly burrowing marine species. (A.W.L.)

ANOMALOUS DISPERSION. Ordinarily the **refractive index** n of a medium decreases with increasing wavelength λ (see **Dispersion**). It often happens, however, that in the immediate vicinity of a certain wavelength λ_1 there is a break or discontinuity in the dispersion curve and the usual rule may be locally reversed (see figure). In some cases there are several such points, λ_1, λ_2, λ_3, $\cdots$. These discontinuities correspond to lines or bands in the **absorption spectrum** of the medium. In the Sellmeier dispersion formula,

$$n = 1 + \frac{A\lambda^2}{\lambda^2 - \lambda_1^2} + \frac{B\lambda^2}{\lambda^2 - \lambda_2^2} + \cdots,$$

the several fractional terms make provision for the respective discontinuities. The absorption wavelengths

$\lambda_1, \lambda_2, \cdots$ and the constants $A, B, \cdots$ must be determined experimentally. If there is pronounced absorption



Variation of refractive index with wavelength, illustrating anomalous dispersion.

and anomalous dispersion in the visible range, the medium appears colored, as illustrated by transparent **dyes.** (L.D.W.)

ANONACEOUS FRUITS. *Anona* sp. Anonaceae. The genus Anona contains shrubs and small trees, many of which bear fruits much esteemed by man. These fruits are composed of many individual ovaries which are more or less sunk in the fleshy receptacle and united to it and to each other. In some species these collective fruits are 5 or 6" in diameter and so heavy as to drag down the branches. *Anona muricata* is the Soursop, whose somewhat acid white pulp is used in making sherbets and drinks. A native of southern Asia, *Anona squamosa,* the Sugar apple or Sweetsop has sweet fruits which are pleasantly fragrant and which are considered by many the most desirable of this group. Another species native in South America is *Anona Cherimola,* in which the fleshy carpels are completely fused. This species grows best at elevations of 4000–6000', and is found in the Andean region. *Anona reticulata,* the Custard-apple, also a native of tropical America, is used locally in the West Indies and elsewhere. None of these fruits has as yet appeared in northern markets. (R.M.W.)

ANOPHELES. Mosquito; Malaria.

ANOPLURA. The order of insects which includes the true or **sucking** lice. They are wingless parasitic insects with mouths formed for piercing and sucking. (See **Louse.**) (A.W.L.)

ANOREXIA. Loss of appetite, or distaste for food. This condition often accompanies the onset of acute illness, fever—especially prolonged fevers, and particularly in chronic wasting disease such as **cancer.** (R.S.M.)

ANORTHITE. Feldspar.

ANORTHOCLASE. Feldspar.

ANORTHOSITE. The name anorthosite was given by T. Sterry Hunt to rocks of **gabbroid** nature which were essentially free from pyroxene, hence almost wholly **plagioclase** *usually* **labradorite.** The term is derived from the French word for plagioclase, anorthose. Small quantities of pyroxene may be present as well as magnetite or ilmenite. The rock is commonly white to gray, bluish, greenish, or perhaps nearly black. A variety from the Province of Quebec is purplish-brown due to the inclusion of ilmenite dust within the feldspars. Although not a common rock in the ordinary sense of the word, occurrences of great areal extent are known in Canada, Norway, and Russia and in the United States in northern New York State and Minnesota. Opinions as to the origin of this rock differ. The development of anorthosite may have been due to the settling out of **labradorite** crystals from a gabbro magma as many believe, or there may have been an original anorthosite magma.

A study of anorthosite occurrences brings out two very curious circumstances, first, that there is no extrusive (lava) equivalent of anorthosite, and second, that most anorthosite masses seem to be of pre-**Cambrian** age. (E.S.C.S.)

ANOXEMIA. Deficiency in the **oxygen** content of the blood. This may be due to insufficient **aeration** of the blood as it passes through the lungs due either to disease of the lung or to circulatory failure, or to insufficient **haemoglobin** content of the blood. (D.M.H.)

ANSERIFORMES. An order of birds including the **geese, swans, ducks,** mergansers, and related species. (A.W.L.)

ANT. Insecta, Hymenoptera. Social **insects** of varied structure and habits. They may be distinguished from the related bees and wasps by the form of the slender

Ant.

petiole which connects **thorax** and **abdomen;** in the ants it is expanded above and looks more or less wedge-like in profile. (A.W.L.)

ANTARES. Antares (*α* **Scorpii**) derives its name from two Greek words signifying that the star is "similar to" or "a rival of **Mars,**" doubtless because of its distinctly reddish hue. In fact, this reddish color has always made the star an object of interest and importance in the ancient religions, and many of the Egyptian temples are so oriented as to indicate that Antares played an important part in their ceremonials. Antares was one of the four royal stars of the Persians about 3000 B.C., and some writers claim that it is the "lance star" referred to in the 38th chapter of the book of Job.

The diameter of Antares has been determined with the stellar **interferometer** and found to be about 390,000,000 miles or slightly greater than the distance of Mars from the sun. It is a typical M **spectral type** giant star of very low density. (W.K.G.)

ANT-BEAR. A name applied to the great **ant-eater,** *Myrmecophaga jubata,* of South America and to the **aard-vark** of South Africa. (A.W.L.)

ANT-BIRD. Aves, Passeres. Several species of birds (*Aves*) found in the forests of Brazil, named from their fondness for ants. (A.W.L.)

ANT-EATER. Mammalia. Any member of the class which is highly specialized for a diet of ants or termites. The specializations are a slender elongate snout, a long sticky tongue which aids in gathering a sufficient number of the small prey, and strong claws for tearing open ant nests.

The ant-eaters include the spiny ant-eaters or **echidnas** of the Australian region, which are monotremes, the

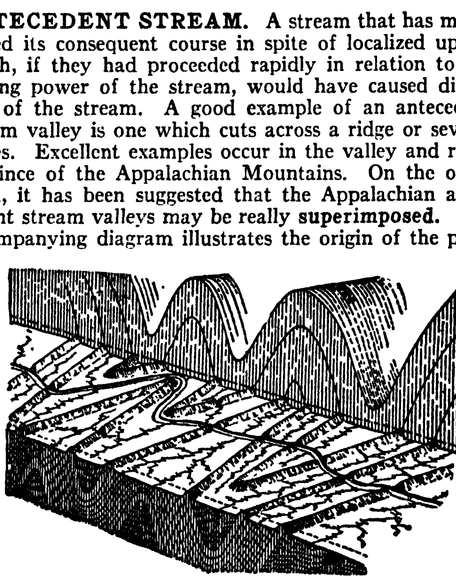
Echidna. (*N. Y. Zool. Soc.*)

aard-varks of Africa (Order Tubulidentata), the scaly ant-eaters or **pangolins** of the Oriental region and Africa and the **ant-bear**, tamandua (*Tamandua tetra-*

Giant ant-eater. (*N. Y. Zool. Soc.*)

dactyla), and 2-toed ant-eaters (*Cyclopes didactylus*) of Central and South America (Order Edentata). The banded ant-eater (*Myrmecobius*) is an Australian **marsupial** of more squirrel-like appearance than the more highly adapted species. (A.W.L.)

ANTECEDENT STREAM. A stream that has maintained its consequent course in spite of localized uplifts which, if they had proceeded rapidly in relation to the cutting power of the stream, would have caused diversion of the stream. A good example of an antecedent stream valley is one which cuts across a ridge or several ridges. Excellent examples occur in the valley and ridge province of the Appalachian Mountains. On the other hand, it has been suggested that the Appalachian antecedent stream valleys may be really **superimposed.** The accompanying diagram illustrates the origin of the pres-



Block diagram illustrating the structural and erosional history of the Appalachian Range. (*After W. M. Davis.*)

ent topography and stream pattern of the Appalachians. It is postulated that the folds were reduced to a **peneplain** on which were flowing a few master streams. Uplift of the peneplain caused the rejuvenation of the master streams which were able to maintain their courses across the upturned edges of the more resistant strata, while the new tributary stream pattern was largely determined by the less resistant formations. (R.M.F.)

ANTELOPE. Mammalia, Artiodactyla. The antelopes are an extensive group between the oxen and the sheep and goats. Many species occur in Africa and some in India and Tibet. The prong-horn antelope of Western North America belongs to a separate group with hollow horns like the oxen; true antelopes have the horns almost solid.

The antelopes include many species with special names, such as the **eland**, the **kudu**, the **addax**, the **gemsbok**, the **oryxes**, the **gazelles**, the **wildebeests**, the **hartebeests** and others. (A.W.L.)

ANTENNA. In zoology an antenna is a jointed sensory appendage of the head found in several classes of **arthropods. Crustaceans** have two pairs, while **insects, centipedes** and **millipedes** (see **Diplopoda**) have one pair.

In the process of radio communication the power generated in the **transmitter** must be projected or radiated into space and at the **receiver** some of this radiated energy must be abstracted from the passing radio wave and fed into the receiver proper. It is the antenna which radiates the power at the transmitter and which picks up the signal at the receiver. The antenna form ranges from a simple short length of wire for the receiver to an elaborate array of wires or steel towers for large transmitters. When alternating voltage of a high frequency is connected to a conductor which is open at the end a corresponding high-frequency a.c. will flow in the conductor and return to the voltage source through the capacitance between the conductor and the rest of the circuit. This rapid a.c. causes energy to be radiated into space from the conductor. This energy travels out from the conductor and does not return. The conductor in this case is the antenna (of course the various connecting wires of the transmitter also have high-frequency a.c. and hence will radiate to some extent but very inefficiently). The efficiency with which an antenna radiates is determined by its length and configuration, and its location with respect to the ground, surrounding objects, etc. In general, better radiation is obtained when the antenna length is an appreciable part of a wavelength of the radio signal. Thus they are usually such values as quarter-wave, half-wave, etc. In special cases they are made several wavelengths long but, where space is a major consideration, they may be made very short. It is found that a maximum signal is produced at the receiver by the **ground wave** for a vertical antenna slightly over 0.6 wavelength, but due to **fading** phenomena the best service is usually obtained by one between 0.5 and 0.6 wavelength. Other dimensions give best results for long-distance communication with the **sky wave.** It is to be noted that the characteristics of an antenna are governed by its dimensions in terms of a wavelength, so a very short antenna will have the same characteristics at a short wavelength (high frequency) as a much longer one would have at a correspondingly longer wavelength (lower frequency). Thus it is often more feasible to make a high-frequency antenna of the optimum dimensions than it is a low-frequency one. At the very low frequencies lumped inductance is frequently added to adjust the electrical length. The antenna will have the same characteristics used for receiving but, since in receiving, efficiency is not of such great importance as long as sufficient voltage is induced in the antenna by the passing radio wave to actuate the receiver, no great attention is paid to the design of ordinary receiving antennas. For commercial service, however, receiving antennae are specially designed. The usual receiving antenna with modern sets may be just a short piece of wire, but the picked-up signal will be greater for a moderately long one placed in the clear of absorbing (electrical) objects. However, the noise picked up will also increase and often a longer antenna results in less satisfactory reception because of the additional noise. (See **Directional Arrays.**) (L.D.W., L.R.Q.)

ANTENNA ARRAY. Directional Array.

ANTENNA, DUMMY. A dummy antenna is a substitute for an actual antenna used for test purposes. In making comparative tests, calibrations, etc., on **receivers** it is highly desirable to have conditions as near as possible to actual use conditions, yet have them standardized so they may be reproduced or the results on different units accurately compared. To do this a standard dummy antenna is used. The make-up of the antenna varies with different types of sets, being a series circuit with an inductance of 20 microhenries, capacitance of 200 micromicrofarads and resistance of 25 ohms for regular broadcast receivers. For auto radios, short-

wave sets, etc., other circuit combinations are standard. The dummy antenna is connected between the set and the standard signal generator which supplies the radio-frequency test voltages. A dummy antenna consisting of just resistance is frequently used as a load on radio **transmitters** for making preliminary adjustments without radiating a signal. The output power of the transmitter is dissipated as heat in the resistance. (L.R.Q.)

ANTENNAL GLAND. Glands associated with the antennae of certain **crustaceans;** probably excretory. (A.W.L.)

ANTENNAL SCALE. The modified outer branch exopodite) of the second **antenna** in some **crustaceans.** (A.W.L.)

ANTHELMINTIC. A **vermifuge** or a remedy used to rid a patient of worms (see **Drugs**). (R.S.M.)

ANTHER. The terminal part of a stamen, containing the pollen sacs (see **Flower**). (R.M.W.)

ANTHERIDIUM. The structure which gives rise to the **sperm.** In the **algae** it is a single cell, the contents of which may become a single sperm or divide to produce many sperms. In the higher divisions of plants, the antheridium is a multicellular body which contains the sperms. (R.M.W.)

ANTHOCYANINS. Pigments in Plants.

ANTHOPHYLLITE. The mineral anthophyllite is an **orthorhombic amphibole** essentially (Mg, Fe)SiO_3 with **aluminum** sometimes present. This mineral corresponds to **enstatite** and **hypersthene** in the **pyroxene** group. It has a prismatic cleavage; hardness, 5.5–6; specific gravity, 2.8–3.2; luster, vitreous, color, gray, yellow, brown, green or brownish-green; transparent to translucent. Probably always a **metamorphic** mineral; very common in **schists.** Found in Norway, Austria, Greenland, Pennsylvania, Georgia and elsewhere The name is derived from the Latin *anthophyllum,* clove, because of its usual brownish shades. (E.S.C.S.)

ANTHOZOA. The **sea anemones, corals, alcyonarians** and related forms. A class of the phylum **Coelenterata** in which the **polyp** form gains its highest development and the **medusa** is unknown.

Like the **hydrozoan** polyps, these animals have relatively thin walls, due to the thin middle layer (mesogloea), and are approximately cylindrical in form. The base is a disk by which the animal is attached to some support and the opposite end forms an oral disk bearing numerous hollow tentacles surrounding the mouth. The mouth leads into a long tube lined with ectoderm, known as the stomodaeum. In it **ciliated** grooves serve for the passage of currents of water into and out of the enteric cavity. In this cavity radiating partitions, the mesenteries, pass from the wall to the stomodaeum, which they hold in place. Others extend into the cavity from the wall without reaching the stomodaeum. The edges of the mesenteries bear mesenteric filaments with stinging cells. They are important in digestion and respiration. Reproductive bodies also develop in the mesenteries and slender acontia with many stinging cells arise from their edges. Muscle bands in the mesenteries and in the body wall contract the entire animal and close the margins of the oral disk in over the tentacles.

The class is divided into two orders:

Order **Alcyonaria.** Polyp with eight tentacles, pinnately branched. Colonial forms, usually supported by a hard skeleton. The **sea fans,** precious **coral,** and **sea feathers.**

Order **Zoantharia.** Colonial or solitary. Polyp with few to many tentacles, not pinnately branched. Hard deposits formed under the basal disk in some species. The stony **corals** and **sea anemones.** (A.W.L.)

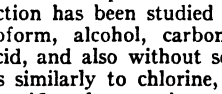
ANTHRACENE. Anthracene

($C_{14}H_{10}$ or )

is a colorless solid, melting point 218° C., having blue fluorescence when pure, insoluble in water, slightly soluble in alcohol or ether, soluble in hot benzene, slightly soluble in cold benzene, transformed by sunlight into para-anthracene ($(C_{14}H_{10})_2$). Anthracene reacts (1) with oxidizing agents, e.g., **sodium** dichromate plus **sulfuric acid,** to form anthraquinone ($C_6H_4(CO)_2C_6H_4$), (2) with **chlorine** in water or in dilute **acetic acid** below 250° C. to form anthraquinol and anthraquinone, at higher temperatures 9,10-dichloroanthracene. The reaction varies with the temperature and with the solvent used. The reaction has been studied using, as **solvent,** benzene, chloroform, alcohol, carbon disulfide, ether, glacial acetic acid, and also without solvent by heating. **Bromine** reacts similarly to chlorine, (3) with concentrated **sulfuric acid** to form various anthracene sulfonic acids, (4) with **nitric acid,** to form nitroanthracenes and anthraquinone, (5) with **picric acid** ($(1)HO \cdot C_6H_2 - (NO_2)_3(2,4,6)$) to form red crystalline anthracene picrate, melting point 138° C. Anthracene is obtained from coal tar in the fraction distilling between 300° and 400° C. This fraction contains 5–10% anthracene from which by fractional crystallization followed by crystallization from solvents, such as oleic acid, and washing with such solvents as **pyridine,** relatively pure anthracene is obtained. Anthracene may be detected by the formation of a blue-violet coloration on fusion with mellitic acid. Anthracene derivatives, especially anthraquinone, are important in **dye** chemistry. (R.K.S.)

ANTHRACITE. Anthracite is the "hard **coal**" of commerce. It contains usually less than 10% of volatile matter and more than 90% of **carbon,** hence burning with a smokeless flame. Anthracite has a high luster and, unlike "soft" or bituminous coal will not soil the fingers when handled. (E.S.C.S.)

ANTHRAQUINONE. Anthraquinone (9,10)



is a yellow solid, melting point 286° C., can be sublimed, forms monoxime, melting point 224° C., by heating under pressure at 180° C. with hydroxylamine chloride, forms no phenylhydrazone with **phenylhydrazine,** with strong oxidizing agents reacts with difficulty to yield phthalic acid ($C_6H_4(COOH)_2(1,2)$), with reducing agents, such as **sodium** hyposulfite, **zinc** in sodium hydroxide solution, tin or **stannous** chloride in hydrochloric acid (but not sulfurous acid), anthraquinone is reduced to

anthraquinol ,

anthrone 
dianthrol 
dianthrone 
depending upon the conditions. Anthraquinone is obtained by oxidation of anthracene using **sodium** dichromate plus **sulfuric acid,** and is purified by dissolving in concentrated sulfuric acid at 130° C. and pouring into boiling water, whereupon anthraquinone separates as pure solid, and is recovered by filtration. Further purification may be accomplished by sublimation or crystallization from nitrobenzene, aniline or tetrachlorоethane. Anthraquinone is used as the material from which many dyes are made, notably alizarin ($C_6H_4(CO)_2C_6H_2(OH)_2$) and related substances. These are vat dyes, that is, insoluble colored substances which are readily reduced to a substance having marked affinity for the fibre to be dyed and which upon exposure to the air are readily reoxidized to the original dye. Anthraquinone may be detected by the appearance of a red color on treatment with alkali, zinc powder and water. For quinones, see **Phenols and Quinones.** (R.K.S.)

ANTHRAXOLITE. A coal-like, metamorphosed **bitumen,** often closely associated with **igneous** rocks. (R.M.F.)

ANTIBIOTICS. Antibiotics are chemical substances secreted by microorganisms, principally fungi and bacteria, which are capable of inhibiting the metabolic activities, growth, or reproducton of bacteria. Some of them can be isolated in quantity and employed in the effective treatment of many stubborn microbial infections and diseases which have resisted earlier attempts to control them. **Penicillin,** for example, inhibits completely the growth not only of pneumococci, streptococci, and staphylococci, but also that of certain strains of gonococci which are resistant to the **sulfonamides.**

Thirty or more antibiotics are now known. Nearly all of them are bacteriostatic, inhibiting the growth of bacteria. Some are bacteriolytic, causing the death and disintegration of bacteria, others merely bactericidal, causing death of the organism without disintegration. Many, unfortunately, are useless in the treatment of disease because they are toxic to man.

Antibiosis is the opposite of **symbiosis.** When colonies of the Ascomycete, *Penicillium notatum,* are grown on the surface of nutrient agar near colonies of *Staphylococcus aureus,* the *Staphylococcus* fails to grow in the immediate neighborhood of the *Penicillium.* Realization of the significance of this particular example of antibiosis led to the isolation of penicillin. The spectacular success of this discovery led to the intensive investigation of many other fungi and bacteria. Several other substances have now been isolated. Many of them are specific in their action; they attack certain bacteria but have no effect on other organisms closely related to them. Some antibiotics interfere with the growth of organisms which cause plant diseases, others with the growth of useful organisms found normally in soil, in water, and in the digestive tract of animals. It is becoming popular to think of them in connection with water and sewage purification. They probably play an important role in the preservation of balance among soil organisms. But their great value lies in the fact that some of them control diseases without bringing harm to diseased tissue of the body. Along with the sulfonamides they provide adequate treatment for wound infection, blood poisoning, pneumonia, meningitis, sore throat, the common venereal diseases, and others; but not, unfortunately, for tuberculosis or the virus diseases. (P.A.W.)

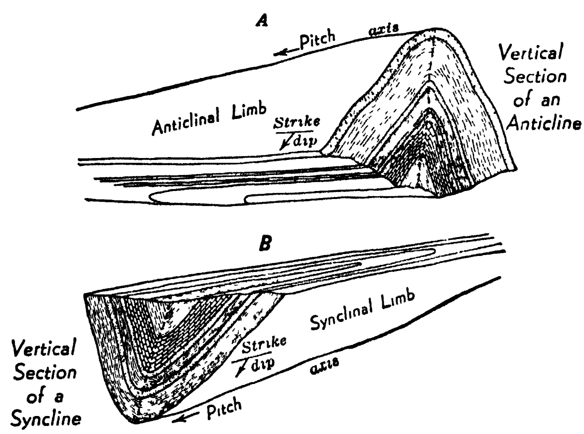
ANTIBODY. When an animal is exposed to infection, there appear in his blood and body fluids soluble substances called antibodies, i.e., bodies acting against introduced substances. Antibodies are also produced on exposure to **antigens** other than bacteria. Any **protein** may act as an antigen and stimulate the formation of specific antibodies. All allergic phenomena come in the category of an antigen-antibody reaction.

In infection, antibodies have a protective and curative value. They act by neutralizing the effect of the antigen. The aim of immunization against disease is the establishment of antibodies in the body. Antiserums are **serums** high in antibacterial or antitoxic antibody content; they are used to combat the effects of the bacteria or their toxins **in scarlet fever, tetanus, and diphtheria.** (D.M.H.)

ANTICLINE. A **folded** structure involving **bedded rocks** in which the strata are arched upward so that the beds bend downward on either side. These downward-bending beds constitute the limbs of the fold.

The angle which the beds on the limbs of the fold make with the horizontal is spoken of as the dip. The term dip is also used to indicate the inclination of bedding in other structures.

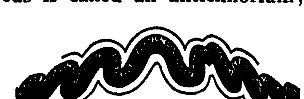
Anticlinal arches may be broad and gentle or sharp with a steep dip, symmetrical or unsymmetrical, or may be complicated by minor folds on the limbs. Anticlinal folds may be of sufficient magnitude to be measured in miles, involving great thicknesses of sediments, or they may be so small as to be measured in inches.



Diagrams illustrating parts of folds. (*After Willis, U. S. Geological Survey.*)

The direction of prolongation of the fold is termed the axis of the fold, and if not exactly horizontal the angle of inclination of the top bed of the anticline is called the pitch. Plunge is used as a synonym for pitch by some writers. (R.M.F.)

ANTICLINORIUM. A composite anticlinal structure of folded beds is called an anticlinorium; a composite



Diagrammatic section of an anticlinorium. (*After Van Hise.*)

synclinal structure is called a synclinorium. The latter term, however, should be applied only to the compressed sedimentary filling of a **geosyncline.** (R.M.F.)

ANTICYCLONE. A relatively large atmospheric eddy, whose dimensions vary from a few hundred miles to several thousand miles. It rotates in a clockwise manner in the northern hemisphere and a counterclock-

wise manner in the southern hemisphere when viewed from above. The barometric pressure within an anticyclone is high relative to its surroundings, and a pressure gradient exists from its center toward its periphery. A well-developed anticyclone is essentially an air mass. It is in general a region of slowly settling air, the rate of descent from aloft being from 300–1500′ per day. Anticyclones are migratory in the region north of 30–40° Lat. Their path is usually to the east and south. Seasonal semipermanent anticyclones develop over both North America and Eurasia during winter. A belt of permanent anticyclones lies between 10 and 40° Lat. with their centers usually over the oceans. Generally speaking, cloudiness is at a minimum in anticyclonic areas and storms are conspicuously absent. In street language, an anticyclone is known as a "high." (P.E.K.)

ANTIDOTE. A drug or **drugs** which counteract a poisonous dose of another drug. This may be accomplished by neutralization, as of an **acid** or **alkali**, or by changing the drug into an insoluble or non-toxic form. Some antidotes are drugs which give the opposite or antagonistic effect in the body to that produced by the poisoning drug. (R.S.M.)

ANTI-FRICTION BEARINGS. Bearings.

ANTIGEN. A substance, usually a **protein**, which stimulates the production of **antibodies** in the body. Bacteria, their toxins, pollens, dust, and many other substances may act as antigens. (D.M.H.)

ANTI-LOGARITHM. Logarithms.

ANTIMONY. Symbol: Sb (stibium). Atomic number: 51. Atomic weight: 121.76. Density: 6.7. Hardness: 3.0–3.3. Melting point: 630.5° C. Boiling point. 1380° C. (**Isotopes:** page 290.)

Antimony is a silver-white metal, brittle and easily pulverized; scarcely tarnished in dry air but oxidized slowly in moist air; burns at a red heat in air or **oxygen** with incandescence forming antimonous oxide; insoluble in **hydrochloric acid;** converted by **nitric acid** into antimonous oxide or antimonic oxide, depending upon the concentration of acid; by **chlorine** into trichloride or pentachloride, by sodium hydroxide solution into antimonite. Discovered by Valentine in 1450.

Antimony is used in alloys, with lead for storage battery plates, with lead and tin in type metals, with tin and copper in bearing or anti-friction metals. Antimony occurs chiefly as the sulfide (**stibnite**, Sb_2S_3) which is produced mainly in China, only small amounts in Mexico and Bolivia. Stibnite is (1) melted and reduced to antimony by **iron** metal and separated from fused ferrous sulfide; (2) is roasted in air and sublimed antimonous oxide collected and reduced by heating to fusion with carbon and sodium carbonate.

Acids: Antimonous acid (ortho, H_3SbO_3, pyro, $HSbO_2$), white solids forming antimonite salts; antimonic acid (ortho, H_3SbO_4, pyro, $H_4Sb_2O_7$, meta, $HSbO_3$), white solids, forming antimonate salts.

Antimonates: Sodium antimonate (pyro, $Na_2H_2Sb_2O_7 \cdot H_2O$, meta, $2NaSbO_3 \cdot 7H_2O$), white solids.

Antimonide: **Silver** antimonide (Ag_3Sb), black precipitate, by reaction of stibine and very dilute silver nitrate solution.

Antimonite: **Sodium** antimonite (meta $NaSbO_2 \cdot 3H_2O$) white solid.

Chlorides: Antimonous chloride, antimony trichloride, "butter of antimony" ($SbCl_3$) white solid, melting point 73° C., boiling point 220° C., by reaction of antimony upon heating with a deficiency of **chlorine,** reactive with water to form antimony oxychloride, antimonyl chloride ($SbOCl$), white solid, soluble in hydrochloric acid; oxychloride, white insoluble solid; antimonic chloride ($SbCl_5$), pale yellow liquid, boiling point 140° C., by reaction of antimony upon heating with an excess of chlorine, reactive with water to form oxychloride, white insoluble solid.

Hydride. See Stibine.

Oxides: Antimonous oxide, antimony trioxide (Sb_2O_3), white solid when cold, but yellow when hot, formed (1) by burning antimony in air or **oxygen,** (2) by reaction of dilute nitric acid and antimony, melting point 656° C., sublimes at 1550° C. (in the absence of air); antimony tetroxide (Sb_2O_4), white solid, by heating antimony metal, trioxide, pentoxide, or trisulfide in air at 800°–900° C. for some time, decomposes above 900° C. to trioxide plus oxygen; antimonic oxide, antimony pentoxide (Sb_2O_5), pale yellow solid, by reaction of antimony metal or trioxide with concentrated **nitric acid,** decomposes on heating, forming tetroxide below 800° C.

Stibine, antimony hydride (SbH_3), colorless, odorless, very poisonous gas, by reaction of a solution of antimony-containing material with a metal (e.g., zinc), and **hydrochloric** or dilute **sulfuric acid** (but not with sodium hydroxide, thus differing from arsine). Stibine, (1) when heated in a glass tube yields a metallic mirror of antimony, (2) when passed into a very dilute solution of **silver** nitrate yields back precipitate of silver antimonide. Stibine burns in air with a faintly bluish-green flame forming antimonous oxide and water.

Sulfides: Antimonous sulfide, antimony trisulfide (Sb_2S_3), orange-red precipitate, by reaction of antimonous salt solution and **hydrogen sulfide,** soluble in concentrated hydrochloric acid, soluble in sodium or ammonium sulfide to form thioantimonite; antimonic sulfide, antimony pentasulfide, "antimony red" (Sb_2S_5), orange precipitate, by reaction of antimonic salt solution and hydrogen sulfide, soluble in concentrated hydrochloric acid, soluble in sodium or ammonium sulfide to form thioantimonate. Used (1) in the manufacture of matches and fireworks, (2) as a pigment, (3) in vulcanizing and coloring rubber.

Numerous organic compounds containing antimony have been prepared, among these are trimethylstibine ($Sb(CH_3)_3$), tetramethylstibonium hydroxide ($Sb(CH_3)_4OH$), which is a strong base, triphenylstibine ($Sb(C_6H_5)_3$).

Solutions of antimony containing substances, when boiled with hydrochloric acid and iron metal, yield a black precipitate of antimony metal

Tartrate: potassium antimonyl tartrate, "tartar emetic" ($K(SbO)(C_4H_4O_6) \cdot \frac{1}{2}H_2O$), white crystals, soluble, by reaction of antimony trioxide and potassium hydrogen **tartrate,** and then crystallizing. Used as a mordant in dyeing textiles and leather, and in medicine.

In alloys, antimony is easily detected by its formation of a white solid upon treatment with concentrated nitric acid and subsequent separation from tin, which is the only other metal thus forming a white solid. (R.K.S.)

REPRESENTATIVE ALLOYS CONTAINING ANTIMONY

Regulus of Venice...	49% Sb	51% Cu

(R.K.S)

ANTIPODAL CELLS. The three usually small cells which occur in the **embryo sac** of **angiosperms** at the end most distant from the micropyle. No known function has been ascribed to them. (R.M.W.)

ANTIPYRETIC. Any **drug** or physical agent which lowers the temperature of the body. Formerly antipyretic drugs were commonly used in **fevers.** Today they

are little used, as fever is considered an index of the resistance of the body to **infection**, and is probably exerting a beneficial effect. The most common antipyretics are "aspirin" (**acetylsalicylic acid**), **quinine**, **antipyrene**, **acetanilid** and **phenacetin**. (R.S.M.)

ANTISEPTIC. Any substance inhibiting the growth of or killing microorganisms, without undue injury to bodily tissues. The chief antiseptics used are: **iodine**, **ethyl alcohol**, "merthiolate," "metaphen," "**mercurochrome**," **phenol**, **picric acid**, **Dakin's solution**, and **azochloramid**. (R.S.M.)

ANTI-SIDE-TONE. In the older types of telephone subscribers' sub-set the sound going into the **transmitter** (mouthpiece) can be heard in the receiver. This is known as side-tone and has some objectionable features. It causes the speaker unconsciously to lower the voice and thus reduces the energy transmitted, and it also increases the effect of any local noise by causing it to appear in the receiver. It is thus desirable to eliminate or at least reduce the side-tone and special circuits and equipment have been devised. These sub-sets are known as anti-side-tone sets. Fig. *1a* shows a conventional

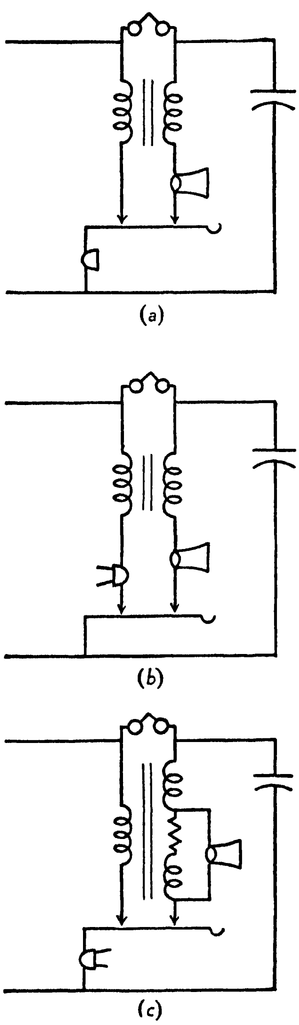

Fig. 1. Sub-set connections.

connection, *1b* a side-tone reduction circuit, and *1c* an anti-side-tone circuit. In the latter the values of the transformer windings and the resistances are so proportioned that the side-tone voltages cancel in the receiver while the incoming signal from the line is impressed on the receiver. (L.R.Q.)

ANTITRADE WINDS. Above the northeast and southeast trade winds there frequently is present a westerly wind known as the Antitrades. Reversal of direction occurs as low as a few thousand feet or as high as 3–4 miles. (P.E.K.)

ANTLER. The large and complex horns of **deer**, consisting of bony outgrowth with no covering of **keratin**. When growing they are covered with skin, the velvet, which is soon lost. (A.W.L.)

ANT-LION. Insecta, Neuroptera. Immature **insects** of the family Myrmeleonidae which lie buried at the apex of conical pits in dry sand or dust. Ants or other small insects which enter the pit slide down the loose slope and are seized by the upturned jaws below. (A.W.L.)

ANT-LOVING CRICKET. Insecta, Orthoptera. *Myrmecophilia.* Small peculiarly formed **crickets** which live in ant nests. (A.W.L.)

ANURA. The **frogs**, **toads**, and allied species; a division of the **Amphibia** characterized by the absence of the tail. Also known as the Salientia from their jumping powers. (A.W.L.)

ANUS. The external opening of the **rectum**. (R.S.M.)

ANVIL. **Forging**

ANVIL HEAD, ANVIL CLOUD. **Clouds.**

AORTA. The main and largest blood vessel of the arterial blood system. It arises from the left **ventricle** of the **heart**, and arching over the root of the left lung, descends along the vertebral column, passing through the chest, and pierces the diaphragm into the abdominal cavity, finally dividing into the right and left iliac arteries in the pelvis. Many large and small blood vessels branch from it. (D.M.H.)

AORTITIS. **Inflammation** of the walls and lining of the aorta at its origin and along its ascending arch. The inflammatory process often spreads to involve the aortic valve, resulting in its dilatation and incompetency. Tertiary vascular **syphilis** is the commonest cause of aortitis. Arteriosclerosis of the aorta and the **endocarditis** of rheumatic fever are sometimes the etiologic factors. (D.M.H.)

AOUL. Mammalia, Artiodactyla. A **gazelle** of northeastern Africa. (A.W.L.)

APAR. Mammalia, Edentata. The 3-banded **armadillo**, *Tolypeutes*, of South America. (A.W.L.)

APATITE. The mineral apatite is a **phosphate** of calcium with either **fluorine** or **chlorine** or sometimes both, hence the distinction between fluor-apatite and chlor-apatite. Sometimes both fluorine and chlorine are present. Most apatite is, however, fluor-apatite.

Apatite crystallizes in the **hexagonal system** in prismatic and tabular forms. Hardness, 4.5–5; specific gravity, 3.17–3.23; luster, vitreous to resinous; transparent to opaque; streak, white; cleavage, imperfect basal and prismatic; color, white, green, yellow, red, brown and purple; sub-**conchoidal** fracture. The variety called asparagus stone is yellow-green and manganapatite which is a dark bluish-green may contain as much as 10% **manganese** dioxide replacing the calcium. Werner devised the name apatite from the Greek word meaning to deceive, as it was frequently mistaken for beryl and other species. Apatite has been found widely distributed

both geographically and petrologically as it occurs in many sorts of rocks, metamorphic **limestones, gneisses, schists, granites** and **syenites, pegmatite** veins and even with **iron** ores. It has been prepared artificially. It has been mined for the manufacture of fertilizers and to a slight extent for jewelry.

Apatite occurs extensively in Europe and America, especially in New England, New Jersey, New York, North Carolina, California, and in the provinces of Ontario and Quebec in Canada. (E.S.C.S.)

APE. Mammalia, Primates. Particularly any of the man-like apes, including the **gorilla, orang-utan, chimpanzee** and **gibbons** (Family Simiidae) but also applied to certain monkeys of another family, such as the Barbary ape. All are tailless. (A.W.L.)

"APE-MAN" OF JAVA. Paleontology of Man.

APERTURE, TELEVISION. In transmitting the **television** image it is necessary to break it down into elements of very small area. In early mechanical scanning methods this was done by "observing" the image through an opening or aperture which scanned the scene. In modern equipment the scanning is no longer done mechanically but the term aperture is used to denote the size of one of the elements into which the picture is broken for transmission. (L.R.Q.)

APHANITE. An aphanite is any fine-grained **igneous** rock whose constituents cannot be distinguished with the naked eye The term is derived from the Greek, meaning invisible. The adjective aphanitic is applied to these rocks as well as their fine-grained groundmasses. (E.S.C.S.)

APHASIA. Diminution or loss of expression by the spoken or written word, or of the understanding of spoken or written language. It is due to injury or disease of the brain centers involving memory, hearing, speech or associated centers. (R.S.M.)

APHELION. Aphelion is the point in the **orbit** of a member of the **solar system,** except a **satellite,** where the object is most remote from the sun. It is the point on the line of apsides diametrically opposite to **perihelion.** (W.K.G.)

APHID, APHIS. Insecta, Homoptera. A plant louse. Small delicate **insects** with sucking mouths. They live on the sap of plants and many species are of economic importance. They are characterized by an intricate life cycle which results in a high rate of reproduction.

In the temperate zone aphids hatch in the spring from winter eggs; these individuals are females known as stem mothers They bear living young without mating (**viviparity, parthenogenesis**) and these in turn are females capable of the same type of reproduction. Late in the season a generation known as the sexuparae bears both male and female offspring which mate to produce the eggs that pass the winter.

Winged aphids appear under conditions which demand migration from plant to plant. Experiments have shown that the appearance of wings is a response to definite environmental conditions, probably complex in nature.

Examples of the economic species are the melon aphid and the apple-grain aphid. Spraying with contact poisons such as nicotine sulfate is effective against all species. (A.W.L.)

APHIS-LION. Insecta, Neuroptera. The **larva** of the golden-eyes or lacewing flies (Family Chrysopidae), so called because they feed on aphids and other small insects. (A.W.L.)

APICAL GROWTH. Growth at the tip of an organ, as occurs in the roots and stems of all higher plants. Examination of the stems of most plants will show that growth in length occurs only in the apical portion, and only for a relatively short period of time, usually a matter of a few weeks. This may be determined by observing the distances between successive leaves· near the growing tip the leaves are very small and close together; as one goes back along the stem the size of the leaves increases and also the distance between them; but after the leaf is mature little elongation of the stem occurs, as shown by the uniform distances between the mature leaves. Older stems increase constantly in diameter, but only exceptionally in length. One notable such exception, known as intercalary growth, is found in grasses and some other plants. Here a group of **cells** in the region of the **node** are capable for a time of active division and of causing increase in the length of older portions of the stem. Both here and in the tip of the stem increase in length is due to elongation of cells produced by an actively dividing tissue known as a meristem. (R.M.W.)

APICAL ORGAN. A **ciliated** structure found in the larvae of **annelid** worms and **Bryozoa.** (A.W.L.)

APLACOPHORA. An order of **Amphineura** made up of animals of worm-like form. (A.W.L.)

APLITE. This term is applied to fine-grained, sometimes sugary-textured **igneous** rocks, composed almost wholly of **quartz** and **feldspar.** Except for size of grain, aplites resemble **pegmatites** both in mineral composition and in mode of occurrence in dikes and veins, save that the rare minerals often present in pegmatites are wanting here. The word aplite is derived from the Greek word meaning simple, referring to its ordinarily simple mineral composition. (E.S.C.S.)

APODA. Gymnophiona.

APODEME. An internal projection of the hard outer covering (**exoskeleton**) of **arthropods.** Apodemes provide muscle attachments and in some species are extensively developed. They are collectively termed the **endoskeleton.** (A.W.L.)

APONEUROSIS. A sheet of tough white glistening **fascia** or membrane which surrounds muscle and muscle fibers or connects a muscle to the part which it moves. The tensile strength and resistance of muscle tissue is dependent upon the fascial tissue around the muscular fibers. (R.S.M.)

APOPHYLLITE. This mineral is a hydrous **silicate** of **potassium, calcium,** and **fluorine,** corresponding to the formula $(KFCa_4(Si_2O_6)_4)8H_2O$. It crystallizes in the **tetragonal system** in square prisms resembling cubes terminated by pyramids; may be tabular, sometimes massive. Cleavage is perfect, parallel to the base; hardness, 4.5–5; specific gravity, 2.3–2.4; luster, vitreous to pearly; transparent to translucent or nearly opaque; color may be white, grayish, greenish, yellowish or reddish. This mineral was named by Haüy from the Greek words meaning from a leaf, referring to its exfoliation when heated with the blow pipe.

Apophyllite is a secondary mineral found with the **zeolites** and has been classed with them by some writers, but it contains no **aluminum,** which element is understood to be an essential in a zeolite. It occurs in cavities in basalts and less often filling openings in granites or other crystalline rocks; it also is a gangue mineral in certain ore veins.

There are many localities for apophyllite: Bohemia, Trentino, Italy, the Hartz Mountains, and Iceland. Fine specimens have been obtained from the Ghats Mountains in India. The Triassic trap rocks of New Jersey, Connecticut and Nova Scotia have also furnished many specimens. (E.S.C.S.)

APOPHYSIS. In zoology, an apophysis is a protuberance or outgrowth of an organic structure, such as a process on a bone.

In geology, an apophysis is a tongue or other direct offshoot of a larger vein or **dike.** (A.W.L., E.S.C.S.)

APOPLEXY. Sometimes called "stroke." Sudden paralysis and coma following a vascular accident in or about the brain or brain stem. The vascular accidents occur as the result of hemorrhage from a cerebral vessel, or **thrombosis** of the blood within the vessel, shutting off the flow of blood to a portion of the brain. **Embolus** to the cerebral vessels occurring in the course of certain types of heart disease, or in chronic suppurative lung disease produces the same picture. Apoplectic seizures occur most commonly in the age group of 40–50 years.

Arteriosclerosis of the vessels at the base of the brain and **hypertension** are the predisposing factors. Formerly it was thought that hemorrhage was from small arteries, but recent work indicates that it is the small veins which give way.

The apoplectic seizure follows immediately in the wake of the hemorrhage. Sometimes there is a premonitory period of dizziness, mental confusion, headache, disturbance of speech. Often the patient is overtaken suddenly, falls to the ground, and rapidly loses consciousness. Depending on the site and size of the hemorrhage, the severity of the seizure varies. At times, there is simply transitory confusion accompanied by the loss of motor power of a limb. If a wide area of brain tissue has been involved, deep **coma** develops. It may last for hours or days, and may be followed by transitory or permanent mental changes, apparent diminution in intelligence and loss of memory.

The paralysis which results from an apoplectic seizure is a hemiplegia, a loss of motor power of the muscles on one side of the body. The face, tongue, arm and leg are involved. At first the paralysis is complete, but gradually over a course of weeks, some power returns; with encouragement and helpful massage and exercise, the patient usually can walk again. The muscles on the affected side become stiff and spastic; contracture of the arm in the flexed position and fixation of the leg in extension tend to occur. (D.M.H.)

APOPYLE. The opening by which a canal in the wall of a **sponge** communicates with the central cavity. (A.W.L.)

APPALACHIAN REVOLUTION. Permian.

APPENDAGE. A supplementary structure attached to an organ or body. Externally many animals have appendages which serve for defense, for locomotion, for securing food, and as sensory organs.

The simplest external appendages are mere outgrowths of the body wall, either solid or hollow; the tentacles of **coelenterates** are an excellent example. In the **annelid** worms both tentacles and parapodia appear as external appendages, in the **echinoderms** the rays or arms may be radiating divisions of the body or appendages, and in the **mollusks** tentacles of complex structure occur. In all cases these structures allow greater facility of movement than is possible for the body as a whole and so compensate the lack of freedom which attends increased size and complexity or sessile habits.

The most elaborate appendages are the jointed appendages of the **arthropods** and **chordates.** Although they are not fundamentally related, the appendages of both phyla are similar in principle. They consist of a series of segments connected by movable joints with each other and with the body, and are provided with muscles which operate them as a series of levers. In arthropods the skeleton is external to the muscles, in the vertebrates internal.

The jointed appendages of arthropods are specialized in various species for swimming, walking, running, jumping and grasping, and in the form of antennae and palpi as sensory organs. In the jumping appendage powerful muscles result in the extension of one segment of the leg, as in the familiar grasshoppers. Grasping is accomplished by the folding back of one segment against another in the insects or by the development of a process on the next to the last segment which works against the terminal segment in a forceps-like relation; the latter is the chelate type of appendage. Arthropod appendages were originally metameric, one pair appearing on each segment of the body. In existing species they are variably limited as described under the term **Arthropoda.**

The **vertebrate** appendage is also specialized for various purposes, including jumping, swimming, flight, and burrowing. The primitive form appears to be the paired fins of the fishes (**Pisces**), and the arms and legs of man are good examples of fairly specialized appendages. Two pairs, the pectoral or anterior pair and the pelvic or posterior pair are typical; only in highly specialized forms such as the snakes is this number reduced.

The **vertebrate** appendage differs from the arthropod appendage in the terminal series of digits. These structures have been developed in some animals so that they can be opposed to each other for grasping, as in the opposition of the human thumb to the four fingers. In other forms they have been reduced in importance.

(**Biramous Appendage, Hand, Fin, Foot, Antenna, Pentadactyl Appendage, Tail, Wing, Telson,** and **Mouth.**) (A.W.L.)

APPENDECTOMY. The surgical removal of the appendix. (R.S.M.)

APPENDICITIS. Appendicitis is an acute inflammatory process involving the **appendix.** It is characterized by abdominal pain, nausea and vomiting, tenderness and spasm of the muscles of the right side of the abdomen, fever, and an elevated white blood-cell count.

At the start of the 19th century the importance of the appendix was not recognized. Inflammation in the right side of the abdomen was believed due to infection about the **caecum** and was called "typhlitis" or "perityphlitis." Isolated reports in the early 19th century showed that the appendix could be involved in an acute process but operations and autopsies were quite rare. The real significance of the disease was recognized by Reginald Fitz, of Boston, in 1886, who first used the term "appendicitis."

Appendicitis is more frequent in highly civilized races than in primitive peoples and is more frequent in urban than in rural districts. The disease is most common between the ages of 10 and 35, although it may occur at other periods.

An attack of appendicitis may subside but, with a virulent infection or with obstruction of the blood supply to the organ, the appendix may become gangrenous or rupture, allowing grossly contaminated material to infect the abdominal cavity. This produces **peritonitis.** Nearly 25,000 individuals die from appendicitis in the United States yearly. In simple acute appendicitis, uncomplicated by abscess or peritonitis, the mortality is less than 1%. But once these complications develop, the mortality soars. Hence, the importance of early operation as soon as the diagnosis of acute appendicitis has been made. Delay and the taking of cathartics during an attack are responsible for the high mortality.

The most important and constant symptom of appendicitis is pain in the abdomen, most frequently in the right lower quadrant. Often the pain at first is around the navel and later shifts to the right lower quadrant of the abdomen. The pain may be constant or intermittent but is usually cramp-like. It varies considerably in severity, depending on many factors such as anatomical peculiarities of the appendix, severity of infection, and degree of obstruction of the appendix. Frequently, with rupture of the appendix the pain be-

comes lessened for a time—a dangerous sign. Other symptoms are nausea and vomiting—the latter following the onset of pain rather than preceding it as in simple gastroenteritis.

The most constant physical finding is tenderness localized over the region of the appendix. Fever may be absent, slight, or moderately high. The white blood count varies but is often either slightly or moderately elevated. It is a valuable confirmatory sign that at times may be misleading (a patient may have a normal blood count with a gangrenous appendix).

In children, the diagnosis of appendicitis is more difficult than in adults and it is for this reason that operation is usually delayed too long.

Treatment for acute appendicitis is always surgical. The earlier surgery is undertaken, the lower the mortality.

Chronic appendicitis is a much-abused term as many so-called cases are due to trouble in organs not having any relation to the appendix. Such cases are not relieved of symptoms by appendectomy. The term chronic appendicitis should be used only to describe an appendix which has been damaged by previous acute attacks of appendicitis. (D.M.H.)

APPENDICULARIAN. Chordata, Tunicata. A free-swimming tailed tunicate. These forms make up the class **Larvacea.** (A.W.L.)

APPENDIX (Appendix Vermiformis). A blind worm-like tubular portion of the intestine which arises from the base of the **cecum.** Its size and position vary greatly, the length averaging 3½", although it has been found to vary from ¾–9". Its position often varies from the normal so that it has been reported in every possible situation in the **abdomen,** depending on the position of the cecum and the length of the organ and its attachments.

An appendix is found only in man, the higher **apes,** and the **wombat,** and possibly in some **rodents.** In herbivorous animals the cecum attains a very large size and it is thought by some that the appendix represents the degenerated remains of the herbivorous cecum. Others believe that it is a **lymph** organ functioning as other lymph glands in the body. By many it is considered to be in the process of gradual obliteration in the human species. It is subject to inflammatory processes because of its limited blood supply, and since it is a blind tube, it is subject to obstruction from fecal impaction. (R S M., D.M.H.)

APPLE. **Rose Family.**

APPLICATIONS OF CHEMISTRY. **Chemistry, Applied Chemistry.**

APPLIED CHEMISTRY. **Chemistry.**

APPROXIMATE INTEGRATION. When the function in the integrand of a **definite integral** is given analytically, the definite integral is usually evaluated by finding the corresponding **indefinite integral** by the methods of **integration technique** and substituting in this the given limits. But it sometimes happens that the indefinite integral cannot be found, and in this case a method of approximate integration must be used. When the integrand function is given empirically by a set of values, the integration technique is not applicable, and in this case also a method of approximate integration is ordinarily used. Formulas for the approximate evaluation of **definite integrals** are given by the following rules:

Suppose we wish to evaluate approximately the integral $\int_a^b f(x)dx$. Divide the interval (a, b) into n equal parts, each of length h, so that $h = \frac{b-a}{n}$. Let the successive values of x in this subdivision be denoted by $x_0(=a)$, x_1, $x_2, \cdots, x_{n-1}$, $x_n(=b)$, and let the corresponding values of the function $y = f(x)$ be denoted by $y_0, y_1, y_2, \cdots, y_{n-1}, y_n$, so that

$$y_0 = f(a),\ y_1 = f(x_1),\ y_2 = f(x_2), \cdots,\quad y_{n-1} = f(x_{n-1}),\ y_n = f(b).$$

The trapezoidal rule is expressed by the formula:

$$\int_a^b f(x)dx \approx \tfrac{1}{2}h(y_0 + 2y_1 + 2y_2 + 2y_3 + \cdots + 2y_{n-1} + y_n),$$

where the coefficients of the y's are all 2 except the first and last. In this case, n may be any positive integer; in general, the larger n is taken, the closer the approximation.

For Simpson's one-third rule (or parabolic rule), the positive integer n must be taken as an even number; the rule is then expressed by the formula:

$$\int_a^b f(x)dx \approx \tfrac{1}{3}h(y_0 + 4y_1 + 2y_2 + 4y_3 + 2y_4 + \cdots + 2y_{n-2} + 4y_{n-1} + y_n)$$

Here also the approximation is in general closer the larger n is taken.

There are additional similar rules known for the approximate evaluation of definite integrals. (L.L.S.)

APPROXIMATIONS, NOTATION. The symbol $\approx$ is put between two expressions to indicate that the right-hand expression is an approximation to the left-hand expression.

Thus, we may write: $\frac{1}{3} \approx 0.33$, $\sqrt{2} \approx 1.414$, $\pi \approx 3.1416$. (L.L.S.)

APRICOT. **Rose Family.**

APSIDES. **Orbit.**

APTERYGIFORMES. An order of birds containing only the flightless kiwis of New Zealand. (A.W.L.)

APTERYGOTA. The primitive wingless **insects.** A subclass made up of the orders **Protura, Thysanura,** and **Collembola** in which the existing species are wingless and there is no evidence to show that wings have occurred in any ancestral form. (A.W.L.)

AQUA. Latin, water, previously used widely by chemists as a term for various solutions in water, e.g., aqua ammonia, solution of **ammonia** in water, ammonium hydroxide; aqua calcis, lime water, **calcium** hydroxide solution; aqua fortis, **nitric acid;** aqua regia, mixture of concentrated nitric and **hydrochloric acids,** named "royal water" because it was the only acid that would attack the noble metal gold. (R.K.S.)

AQUAMARINE. **Beryl.**

AQUARIUM. A water-tight container, usually with glass sides, for the maintenance of aquatic organisms in captivity. Also an establishment for the public exhibition of such displays.

Small aquaria for the home are often of the globular type known as goldfish bowls, blown in one piece, or one-piece rectangular glass vessels. Larger aquaria are made of glass plates set in a metal frame with a specially prepared aquarium cement. The latter require greater care and usually leak when first filled or when shifted later; if well constructed the flexible cement permits adjustment to the changed stresses and the leaks stop automatically. For laboratory purposes larger aquaria are made of a combination of stone slabs and glass plates.

Formerly aquaria for the home were limited to the display of goldfishes but in recent years many species of tropical fishes have been made available. In all cases the purity of the water used and the maintenance of

an adequate supply of oxygen are important factors in the success of the aquarium. The maintenance of tropical fishes is further complicated by the need for higher temperatures than can be found in most homes. These aquaria cannot safely be allowed to drop below 70° F. and should be maintained at 75–80° F. Heating is best accomplished by electric heaters with **thermostatic** control, for which special equipment can be secured from dealers in aquarium supplies.

As a rule a good city water supply is safe for fishes. If not, water from any clear stream or lake where fishes thrive is likely to be safe for aquarium species, or a chemical purifier can be secured from dealers in fishes.

The oxygen supply can be maintained by changing the water frequently but it is better to establish a balanced aquarium by including some water plants such as **Elodea, Vallisneria,** or **Sagittaria.** The plants free oxygen and utilize the carbon dioxide produced by the fishes. Some plants float but others must be planted in a bed of sand or gravel in the bottom of the aquarium. With a little practice pleasing arrangements may be secured by the use of a few rocks and the careful grouping of the plants, and the quantities of plants and fishes may be adjusted so that changes need not be made for months at a time. A good rule to follow is "an inch of fish to a gallon of water." Plants need not be so carefully regulated, for they tend to crowd the aquarium and must usually be thinned from time to time, while fish increase only under the most favorable conditions.

Some common aquarium troubles are the accumulation of **algae,** diseases, and incompatibility of different species of fishes. Once algae are introduced it is difficult to keep them down without complete sterilization and renovation of the aquarium and any sand and rocks that it may contain. Plants should be replaced with clean stock but the fishes may be returned to the aquarium. For the recognition and treatment of diseases and for the proper stocking of the aquarium the fish-fancier should consult a reputable dealer or one of the excellent books on aquarium fishes now on the market.

A few snails and bottom-feeding fishes included in an aquarium play a useful part as scavengers. The flocculent wastes that inevitably accumulate at the bottom in the course of time can be siphoned off by means of a flexible tube. Some water is necessarily carried off, hence, after cleaning the aquarium, enough should be added to bring the contents to their normal level.

While convenience must often determine the location of an aquarium in the home, plants will not thrive without some sunlight so a balanced aquarium must be kept near a window. North light is by far the best. If the sun's rays must strike the aquarium directly, it should be only for a short time during the day.

Among the aquaria where large public exhibits of fishes are maintained may be mentioned the Shedd Aquarium in Chicago, Steinhart Aquarium at San Francisco, the Naples Aquarium, London Zoological Gardens, the Bermuda Aquarium, and the Honolulu Aquarium. The two last are famous for the brilliant tropical fishes which they exhibit from neighboring waters. (A.W.L.)

AQUARIUS. (The water bearer.) (Map, page 380.) This **constellation** is the eleventh sign of the **zodiac** and is of importance solely because of that fact. There is a theory that the constellation received its name because the sun is in this part of the sky during the rainy season in the Euphrates valley.

Though the constellation is relatively large it contains no bright or particularly striking features. (W.K.G.)

AQUEDUCT. An artificial conduit built to carry water is called an aqueduct. Generally speaking, aqueducts are built to convey a fresh water supply to congested districts from suitable sources more or less distant, and are therefore peculiar to cities. The first settlers in a place may depend upon local springs, streams, and wells, but with the growth of population there comes a time when these will prove inadequate, and suitable distant water supplies may have to be tapped through the medium of the aqueduct.

An aqueduct may be either a pressure or grade-line type. Pressure conduits are commonly employed for small capacities or adverse topography, open or grade-line conduits for large capacity or favorable topography. Circumstances may require both types on the same project as the most economical combination. Pressure tunnels can convey water at pressures considerably above atmospheric, and are constructed with circular cross-sections. They are most frequently found in tunnel sections cut through hills and mountains, and in siphons. The principal distinguishing hydraulic characteristic of the pressure aqueduct is that it may depart from the normal open flow line both above and below the normal **hydraulic gradient.** However, siphon action, for sections above the hydraulic gradient, should be avoided wherever possible. Grade-line sections of aqueducts are usually built with open cut and fill construction following a hydraulic grade-line which will yield the requisite flow in the aqueduct at approximately atmospheric pressure, i.e., the fall per mile being just sufficient to overcome the friction loss in the same distance.

Some of the most important of the ancient aqueducts were those supplying the city of Rome, among which might be mentioned the Marcian, with a length of 58 miles, the Julian, a length of 17 miles, and the Claudian, with a length of 43 miles. These were high level aqueducts of the grade-line type, principally cut and fill where possible, with grade-line tunnels for piercing hills, and resting on multiple arches when spanning valleys. These older aqueducts rarely had cross-sections greater than 30 sq. ft. in area. The Catskill aqueduct which conveys the water of the Ashokan Reservoir to the City of New York, approximately 100 miles away, has a capacity of 500,000,000 gals. a day and is a splendid example of modern engineering on a large scale. It has in places cross-sections greater than 150 sq. ft. in area, inverted siphons, one going more than 1000′ below sea level, as well as a score of tunnels. (C.W.C., F.T.M.)

AQUEDUCT OF SYLVIUS. The portion of the central canal of the **nervous system** of **vertebrates** which lies in the mid-brain, connecting the third and fourth ventricles. (A.W.L.)

AQUEOUS VAPOR. Water vapor is known as aqueous vapor. It varies from 0.01–3.0% of the total atmosphere, depending on the temperature, source, and history of the air in question. Aqueous vapor enters the air by evaporation from oceans, lakes, rivers, and other small bodies of water, from precipitation, from water films on surface objects, from transpiration of plants. It exerts a partial pressure which is added to the total air pressure. (P.E.K.)

AQUIFER. **Ground Water.**

AQUILA. (The eagle.) (Map, page 380.) A constellation lying in the **milky way** and hence containing rich star fields when viewed with a low-powered **telescope.** The distinguishing feature of this constellation is the group of three stars almost in a straight line, with the bright star **Altair** between two fainter ones. Several **Novae** have appeared in this constellation, the most famous one being Nova Aquilae III of 1918. (W.K.G.)

AQUINO'S METHOD. **Celestial Navigation.**

Æ. Symbol for **Aspect Ratio** of an object, especially an airfoil or wing. (F.T.M.)

ARABINOSE. **Carbohydrates.**

ARACHIS OIL. **Esters.**

ARACHNIDA. A class of the phylum **Arthropoda** including the **spiders, mites, ticks, scorpions,** pseudoscorpions, **whip scorpions,** sun spiders and **harvestmen.** Next to the insects this class is probably the best known among the invertebrates.

Arachnids differ from the other members of the phylum in one or more of the following characters: 1. The body is usually divided into two regions, a **cephalothorax** and abdomen. 2. Only simple eyes are present. 3. There are no **antennae.** 4. The **thorax** bears four pairs of legs in the adult. 5. The **abdomen** is often unsegmented and bears no appendages. 6. The first pair of appendages are **chelate** grasping organs. 7. Respiration is carried on by **tracheae** or **lung-books.**

Arachnids are almost exclusively terrestrial and are predominantly predacious or parasitic, although some of the mites are plant feeders and the harvestmen include vegetable materials among their food.

The development of poison glands is fairly general in the group. Spiders have such glands, opening in the jaws or **chelicerae,** and scorpions have a special sting at the tip of the abdomen. With the exception of the black-widow spider of the United States and a small scorpion found near Durango the poison is not known to be harmful to man. There is some probability that these two species may sometimes inflict fatal wounds.

The secretion of silk by spiders is another salient feature of the group. Silk glands are located in the abdomen, discharging through a group of spinnerets near the posterior end of the body. The silk is used to build webs of various forms for snaring prey, for the construction of cocoons to receive the eggs, as a lining for burrows, and in some cases as a vehicle to carry the animal on currents of air.

The economic importance of arachnids is rather limited. Spider silk has been woven but it is too delicate for extensive use and is valuable only as a source of cross-hairs for optical instruments. Aside from the poisons mentioned above, the principal harm from these animals is derived from the mites and ticks. The ticks do some damage to man and domestic animals by sucking blood but their greatest damage is due to the transmission of diseases. Texas fever of cattle, Rocky Mountain spotted fever of man, and other diseases are so conveyed. Mites living in the hair follicles, the **sebaceous glands,** and the tissues of the skin cause such diseases as scab in sheep and itch in man. Plant-feeding species of economic importance include the bulb mite, the pear blister mite and various gall mites.

The classification of the arachnids is briefly as follows:

- Order Scorpionida. The **scorpions.** Abdomen divided into a preabdomen and a slender postabdomen bearing a claw-like sting at the tip.
- Order Pedipalpi. The **whip-scorpions.** Anterior pair of legs slender and antenna-like.
- Order **Solpugida.** The sun spiders. Head and thorax separate.
- Order Chelonethida. Pseudoscorpions. Very small scorpion-like animals; no postabdomen nor sting.
- Order Phalangida. **Harvestmen** or daddy longlegs; commonly regarded as spiders but have a segmented abdomen broadly joined to the thorax.
- Order Araneina. **Spiders.** Abdomen unsegmented and joined to the thorax by a slender waist.
- Order Acarina. **Mites and ticks.** Small to moderate species with a sac-like body showing no well-marked divisions. (A.W.L.)

ARAGONITE. The mineral aragonite is **calcium** carbonate, $CaCO_3$, chemically identical with **calcite** but **crystallizing in the orthorhombic system,** with acicular crystals. By repeated twinning, pseudo-hexagonal forms result. Aragonite may be columnar or fibrous, occasionally in branching **stalactitic** forms called flos-ferri (flowers of iron) from their association with the ores at the Carinthian iron mines. Its hardness is 3.5–4; specific gravity, 2.93–2.95; luster, vitreous to resinous; colors, white, gray, green-yellow or purple; transparent to translucent. Aragonite forms at temperatures of 80–100° C. and is relatively unstable at ordinary temperatures and pressures. It alters to calcite, although very slowly. There are many localities for aragonite in Europe, Bolivia, Pennsylvania, Iowa, Missouri, South Dakota, New Mexico, Arizona and Colorado. Its name is derived from Aragon in Spain. (E.S.C.S.)

ARANEINA. **Arthropoda; Arachnida. The spider.**

ARAPAIMA. Pisces, Teleostei. A large fish (**Pisces**), *Arapaima gigas,* of the rivers of northern South America. It attains a length of 15′ and a weight of more than 400 lbs. Also applied to related fishes of several genera. (A.W.L.)

ARAUCARIA. Coniferous trees found in southern South America, Polynesia and Australia. *Araucaria imbricata,* the "Monkey puzzle" tree of South America, reaches a height of 150′. *Araucaria excelsa,* the Norfolk Island Pine, is frequently seen in florists' windows and in collections of living plants, where it finds place because of its elegant symmetry. In its natural habitat it becomes a tree reaching a height of 200′ or more. (R.M.W.)

ARBOR. A shaft or stud, usually cylindrical or conical, on which a cutting tool, a tool holder, or a part to be machined is mounted or held. (H.C.H.)

ARBUTUS. **Heath Family.**

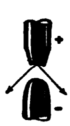
ARC BACK. This is the occurrence of an arc from **anode** to **cathode** in a gaseous rectifier **tube.** Normally such a tube has **electrons** flowing from the cathode to the anode but under certain conditions excessive heating of the anode, excessive voltage across the tube, or other effects may cause the anode to emit electrons and allow an arc discharge to take place in a direction opposite to the normal direction. Under many circuit conditions this may destroy the tube or it may merely open the protective devices. (L.R.Q.)

ARC DISCHARGE. The electric arc, so called because of the shape of the "flame," was discovered by Davy about 1808. It is a type of discharge between electrodes in a gas or vapor which is characterized by a relatively low voltage drop and a high current density. The two types which are of considerable practical importance are the arc in open air and the arc in gases at low pressure. The familiar **carbon-arc** (see **Arc Lamp**) and the electric-arc furnace are examples of the former. In this type the arc is started by impressing a voltage across the electrodes in contact and then separating them. At the instant of breaking contact the high field and current density initiate the arc. Thereafter, if the current is kept constant, the potential necessary is a linear function of the inter-electrode distance. In its steady state the arc has an intensely hot cathode which emits a plentiful supply of electrons. The energy for heating the cathode is obtained from the high current density and from the bombarding positive ions. The arc is thus apparently a **thermionic phenomenon.** If the carbons are impregnated with a volatile metallic salt, the result is a "flaming arc," useful in producing the arc **spectrum** of the metal. If a d-c carbon arc is placed in parallel with a suitable condenser and an inductance, the circuit so formed may be made to oscillate, as discovered by Duddell, and to serve as a source of undamped electric waves. (See **Ionized Gases.**)

The arc is one of the most serious problems in switching electrical circuits, since the separation of the switch or **circuit breaker** contacts establishes an arc which must be extinguished in order to break the circuit. Many schemes have been developed to accomplish this. (See **Circuit Breaker.**)

The **mercury-arc tube** is the most important example of an arc in a gas at low pressure. Here the gas is the mercury vapor, the **cathode** is the mercury pool, and the **anode** is usually carbon. The arc is initiated by breaking contact between the mercury pool and a starting electrode. In gases at low pressure an arc may be established without breaking contact between the electrodes if the impressed voltage is high enough. If the voltage impressed across two electrodes separated by a low-pressure gas is gradually increased the current increases slowly at first due to the residual ions and electrons present in the gas. The electrons ionize the gas molecules upon colliding with them, thus giving rise to additional ions and electrons to carry the current and also to produce more ionization by collision. This process continues until suddenly the breakdown voltage is reached, when the current increases very rapidly, even if the voltage is lowered. This is the initiation of the glow discharge. If the circuit resistance does not limit the current the discharge progresses almost instantaneously into an arc discharge having the distinguishing features of the regular arc. The discharge in **thyratrons** and other gas-filled hot cathode tubes is often called an artificial arc discharge since it is characterized by low voltage and high current density. It is not a true arc however since the cathode heat energy is supplied by an external source and not by the discharge itself. (L.D.W., L.R.Q.)

ARC LAMP. The electric-arc lamp has, as its source of illumination, an electric arc struck between two electrodes. In contrast to the incandescent lamp, in which the illumination results from a heated filament, and vapor lamps, in which the illumination is derived from a vapor made luminous by electric current, the light from an arc lamp comes from the highly incandescent crater of one of the electrodes, and from the heated, luminous, ionized gases surrounding the arc. The positive electrode, having the crater, is mounted above the negative one. The light is largely directed downward from the crater. To start the arc the electrodes are brought into contact and then separated a short distance. The arc which follows vaporizes the electrode material slightly, forming a conducting ionized vapor which bridges the space separating the electrodes. The separation distance is maintained by a series-connected **solenoid.**



Arc-lamp electrodes.

The principal electrode material employed is carbon containing mineral salts which tend to intensify the flame between the electrodes. In any arc lamp using other than plain carbon electrodes, there is the problem of disposing of the fumes of the arc so that the enclosing glass globe will not be discolored, and in all such lamps, carbon or otherwise, there is a steady consumption of electrodes when the lamp is in use, necessitating their replacement every 50 to 150 hours of use. The light from arc lamps is very much more intense than that from the incandescent type lamp. From the standpoint of current consumption, the illumination is produced efficiently. Some arc lamps may not be operated on a.c., but all types are adaptable to d.c. A constant current series type circuit is used to operate street-light arc lamps, as that is found to be the most economical way to distribute the electrical energy over a large territory. (F.T.M., L.R.Q.)

ARC WELDING. Welding.

ARCH. An arch is a curved beam, made of **wood, brick, stone, concrete** or **steel,** whose supports are able to exert **lateral** as well as vertical forces to resist the action of any applied **loads.** These lateral forces are in the nature of thrusts which act inwardly toward the center of the arch span. The curvature of the beam must be in an upward direction in order to develop lateral **reaction** forces which will act in the required direction.

Brick arches are generally used to support walls above windows or doorways although they may be used for small **bridges** or **culverts.** In the past, brick arches of considerable magnitude have been constructed although at present brick is not commonly employed for major arch construction. **Masonry** arches are composed of stone blocks called voissoirs. They derive their load-carrying capacity from the fact that the shape of the arch ring is such that **compression** is the only type of **stress** caused by the **resultant** reaction on the end of any voissoir. Reinforced **concrete** arches, as the name implies, are composed of concrete and steel rods, the latter added primarily for the purpose of carrying any tensile stresses which may occur. Steel arches are subdivided into two classes: namely, the solid rib and open rib types. The solid rib arch is composed of structural shapes similar to those comprising a **plate girder** while the open rib arch is constructed of structural shapes forming triangles like those in a simple **truss.**

These structures may be further classified as fixed or hinged arches. A fixed arch is a structure which is rigidly connected to its supports in such a manner that they exert vertical and lateral reactions and prevent rotation. A two-hinged arch is one which is free to rotate about its supports, consequently they are able to exert only vertical and lateral reactions. Three-hinged arches have an additional hinge midway between the hinges at the supports. The tied arch is a structure in which the lateral forces are applied by means of a horizontal **tension** member connecting the ends of the arch. (C.W.C.)

ARCH BRIDGE. Bridge.

ARCH DAM. Dams.

ARCHAEOPTERYX. Fossil Birds.

ARCHAEOTHERIUM. Fossil Mammals.

ARCHEGONIATES. Those plants in which the female sex organ is an **archegonium** are called Archegoniates. (R.M.W.)

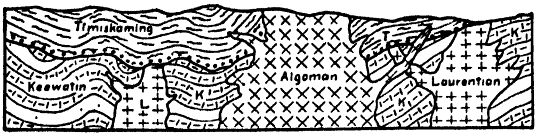
ARCHEGONIUM. The multicellular female sex organ characteristic of **Bryophytes, Pteridophytes** and **Gymnosperms.** It consists of a swollen basal portion called the venter, and an elongated neck. The venter may be a single layer of **cells,** but is often many cells thick. Within the basal portion is contained the single large egg, and a second, somewhat smaller, ventral canal **cell,** while the elongated neck contains a single row of cells which eventually dissociate, leaving an open canal through which the **sperm** may pass to reach the egg. (R.M.W.)

ARCHENTERON. Enteric Cavity.

ARCHEOCYTE. Cells of **sponges** which ingest and digest food, carry the products to other parts of the body, and form reproductive cells. They are amoeboid (see **Amoeba**) and are found in the mesenchyme (see **Mesenchymal Tissues**). (A.W.L.)

ARCHEOZOIC. (Archean.) The oldest of the five Eras of the earth's history. The rocks of this **System** are **metamorphosed** equivalents of all types of **sedimentary** and **igneous** rocks, but principally the latter. No undisputed fossils have been found in the Archean.

The lower Archean (Keewatin) of North America is composed of a preponderance of metamorphosed, basaltic lava flows and tuffs with some metamorphosed



A highly generalized section, about 25 miles long, showing the relations of the Archeozoic group of rocks in the Lake Superior-Lake Huron region of Canada. The Keewatin system was moderately folded and intruded by the Laurentian granite, after which there was deep erosion. Then the Timiskaming rocks were laid down, and later strongly folded and intruded by the Algoman granite, after which there was another period of profound erosion, marked by the upper surface.

sediments, such as **quartzite** and **slate**. The general character of the basal Archean proves that the oldest known rocks do not represent the original crust of the earth. The upper Archean (Laurentian) contains a preponderance of **granite, gneisses,** and **schists** in the form of **batholiths** intruding the Keewatin. The principal areas of Archeozoic rocks are in Canada, Finland, Scandinavia, Australia, Africa and northeastern South America. Many of the formations contain rich ore deposits, especially of gold and silver. Large amounts of graphite suggest the former existence of life. Length of time since the beginning of the Archeozoic, possibly 2000 million years. Owing to the lack of fossils, structural complexity, high degree of vulcanism and **metamorphism,** geologists have found great difficulty in deciphering the history of this earliest recognizable portion of the "crust" of the earth. The structural history of the Archean is therefore not so well known as that of the succeeding periods and intercontinental correlation is particularly difficult. On the other hand, the search for ore deposits has been an important stimulus to the study of the Archean formations, especially in Canada. (R.M.F.)

ARCHIANNELIDA. A class of **annelid** worms including small marine species of simple structure. (A.W.L.)

ARCHIMEDES' PRINCIPLE. Buoyancy.

ARCTIC AIR MASS. Air Masses.

ARCTIC SEA SMOKE. Fogs.

ARCTURUS, (α **Bootes**). Arcturus was probably one of the first stars to be named. It probably received its name because of its proximity to the constellation of **Ursa Major,** the name indicating that it is the "watcher of the bear." The name Arcturus is one of the few star names to be referred to in the Bible, being found in Job IX, but from the remainder of the verse there is evidence that the name Arcturus in this quotation actually refers to the constellation of Ursa Major rather than to the actual star itself. References to Arcturus are to be found in the writings of many of the ancient poets, including Virgil. **Astrologically,** the star portended honor and riches.

Arcturus is one of the few stars whose diameter has actually been measured with the stellar **interferometer.** The angular diameter is found to 0".020 which, when combined with its **stellar parallax** of 0".080, indicates a linear diameter of about 27 times that of our **sun.** (W.K.G.)

AREA, EQUIVALENT FLAT-PLATE. Flat-Plate Area, Equivalent.

AREA, SERVICE. This term is used to designate the coverage area of a broadcast station and is usually divided into a primary service area and a secondary service area. The first is that area around the station in which reliable reception strong enough to override local noises, interference, etc., is obtained. The signal strength necessary to do this varies from 0.1 millivolt per meter for quiet rural locations to around 10 millivolts per meter for a metropolitan location. Coverage in this area is by the **ground wave** and hence is not subject to seasonal or diurnal variations. The secondary service area is the area where reception is fairly good but is not as perfect as the primary area. The signals here may be due to the ground wave or **sky wave.** Daytime reception in the secondary area is by ground wave but the night time area is often greatly extended by a useful sky wave signal. Excessive interference between the sky wave and ground wave may cause reduction of the night secondary area. (See **Fading.**) (L.R.Q.)

AREA ON A CURVED SURFACE. With a very few exceptions, the area of a portion or all of a given curved surface can only be found by use of methods of the **calculus.**

If an arc of a **curve** whose equation in **rectangular coordinates** is $y = f(x)$, between **ordinates** $x = a$ and $x = b$, is revolved about the X-axis, the area of the **surface of revolution** generated is given by

$$S = 2\pi \int_a^b y ds = 2\pi \int_a^b y \sqrt{1 + \left(\frac{dy}{dx}\right)^2} \cdot dx.$$

If an arc of a **curve** whose equation is $x = \phi(y)$, between **abscissas** $y = c$ and $y = d$, is revolved about the Y-axis, the area of surface generated is given by

$$S' = 2\pi \int_c^d x ds = 2\pi \int_c^d x \sqrt{1 + \left(\frac{dx}{dy}\right)^2} \cdot dy.$$

If the equation of a surface in rectangular coordinates is $z = f(x, y)$, the area of a portion S of the surface is given by the **double integral**

$$S = \iint_S \left[1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2\right]^{1/2} dxdy.$$

If the equation of the surface is $F(x, y, z) = 0$, the area of S is given by

$$S = \iint_S \frac{\sqrt{\left(\frac{\partial F}{\partial x}\right)^2 + \left(\frac{\partial F}{\partial y}\right)^2 + \left(\frac{\partial F}{\partial z}\right)^2}}{\left[\frac{\partial F}{\partial z}\right]} dS.$$

(L.L.S.)

AREA UNDER A PLANE CURVE. One of the simplest interpretations of the **definite integral** is by the area under a plane curve.

If $y = f(x)$ is the equation in **rectangular coordinates** of a **plane curve,** the area between this curve, the X-axis and two **ordinates** $x = a$ and $x = b$, is given by the **definite integral**

$$A = \int_a^b y dx = \int_a^b f(x) dx.$$

If the equation in rectangular coordinates of the curve is $x = \phi(y)$, the area between this curve, the Y-axis and two **abscissas** $y = c$ and $y = d$ is given by

$$A = \int_c^d x dy = \int_c^d \phi(y) dy.$$

If the equation of the curve in **polar coordinates** is $r = f(\theta)$, the area bounded by the curve, two fixed radii vectors $\theta = \alpha$ and $\theta = \beta$ is given by

$$A = \tfrac{1}{2} \int_\alpha^\beta r^2 d\theta.$$

(L.L.S.)

ARECA. Betel Nut.

ARENACEOUS. A textural term applied to sediments or **sedimentary** rocks which are composed of grains of sand. Psammitic has the same meaning. (R.M.F.)

ARGALI. **Sheep.**

ARGAND'S DIAGRAM. **Complex Numbers.**

ARGENTITE. The mineral argentite, sometimes called silver glance, is naturally occurring **silver** sulfide, corresponding to the formula Ag_2S. It crystallizes in the **isometric system** in cubes, octahedrons and dodecahedrons, or may be massive. Hardness, 2–2.5; specific gravity, 7.2–7.36; luster, metallic; streak, gray; color, black, blackish-gray or gray; opaque and sectile to such an extent that it cuts like wax with a knife. Heated upon charcoal it yields a malleable mass of silver. The name is derived from the Latin word for silver, *argentum*.

Foreign localities for fine crystals are Sonora, Mexico, and Freiberg, Saxony; in the United States at Butte, Montana; Tonopah, Nevada; and Aspen, Colorado.

Argentite is probably the most abundant ore of silver. Acanthite a rare **orthorhombic** silver sulfide has the same chemical composition and recent studies seem to show that it is a **low-temperature** form while argentite is the high-temperature form of this compound. (E.S.C.S.)

ARGENTUM. **Silver.**

ARGILLACEOUS. This term is used to designate **sedimentary** rocks composed of fine particles of the nature of clay or mud. Pelitic has the same meaning. (R.M.F.)

ARGILLITE. A dense, fine-grained, hard, **sedimentary** rock of various colors (usually white, gray or red). Composed of minute grains of both **clay** and **quartz.** Certain types of argillites are easily confused with certain types of fine-grained acid **lava** flows, such as felsites, unless studied microscopically. (R.M.F.)

ARGININE. **Aminoacids.**

ARGON. Symbol: A. Atomic number: 18. Atomic weight: 39.944. Density: 1.784 grams per liter, 0° C., 760 mm., or 1.380 when air is taken as 1.000. Melting point: −189.2° C. Boiling point: −185.7° C. Isotopes: 36 (0.31%), 38 (0.06%), 40 (99.63%).

Argon is a colorless, odorless gas, which does not react chemically under ordinary conditions. Discovered by Rayleigh and Ramsay in 1894, in ordinary air to the extent of 0.93%. The discovery was due to the investigation into the discrepancy of the density of **nitrogen** from the atmosphere and from chemical compounds. It appears that Cavendish a century earlier had made the observation that a small portion of air remained when nitrogen was sparked with oxygen. Argon shows a pale red glow in a vacuum electric discharge tube. Commercially, argon is used instead of nitrogen as the atmosphere of **tungsten** electric light bulbs. (R.K.S.)

ARGONAUTA. Mollusca, Cephalopoda. The genus to which the paper nautilus belongs. This species is not a true nautilus but is more closely related to the octopus. (A.W.L.)

ARGYRIA. Poisoning from the use of **silver** preparations over too long a period, causing a ghastly bluish discoloration of the skin over the entire body. (R.S.M.)

ARID REGIONS. Areas in which the rainfall is insufficient to support vegetation. Large parts of the western United States are semi-arid where sufficient rain falls only for a short period in any given year to support vegetation. (P.E.K.)

ARIES. (The ram.) (Map, page 380.) This **constellation** is far more famous from its classical significance than because of its appearance in the sky. It contains no bright stars and has no conspicuous features. Two thousand years ago the **vernal equinox** was located in the constellation of Aries and the symbol for the vernal equinox is the symbol for the constellation (i.e., the ram's head). **Precession** has caused the position of the vernal equinox to move backwards into the constellation of **Pisces** so that now the "sign of the first of Aries" is to be found in that constellation. (W.K.G.)

ARIL. In many plants there is formed in the developing fruit an outgrowth from the funiculus, or seed stalk, one which completely or partially surrounds the seed. In the litchi nut it is the thick translucent pulp surrounding the seed; in the nutmeg it is a mesh-like envelope which when removed and dried is known as mace. (R.M.W.)

ARISTOGENESIS. A principle of **evolution** formulated by Henry Fairfield Osborn, based upon observation of successive changes in fossil series. It postulates the origin of new characters in living things in adaptation to the environment and was expressed by its author as "the creative origin of the adaptive." (A.W.L.)

ARISTOTLE'S LANTERN. The masticating apparatus of the sea-urchin (**Echinoidea**). It consists of five jaws, each bearing a tooth, and five radial pieces (rotulae) which unite the bases of the jaws. (A.W.L.)

ARITHMETIC. Arithmetic, as generally understood, deals with the operations with numbers and their practical applications; it may be described as the art of computation and the applications of this art. (L.L.S.)

ARITHMETIC MEAN. In a **serial distribution** the arithmetic mean $\bar{X}$ (commonly called the **mean**) is the sum of the **variates,** x_i, divided by the number of variates, N.

$$\bar{X} = \frac{\Sigma x_i}{N} = \frac{x_1 + x_2 + x_3 + \cdots + x_N}{N}.$$

In a **frequency distribution** the formula for the mean becomes

$$\bar{X} = \frac{\Sigma f_i x_i}{\Sigma f_i} = \frac{f_1 x_1 + f_2 x_2 + f_3 x_3 + \cdots + f_N x_N}{f_1 + f_2 + f_3 + \cdots + f_N}$$

where f_i = frequency in the ith class and x_i is the class mark in the ith class. For computational purposes an arbitrary origin a is chosen and we have the formula

$$\bar{X} = a + c\,\frac{\Sigma f_i d_i{}^1}{\Sigma f_i}$$

where $d_i{}^1 = \dfrac{x_i - a}{c}$ and c is the **class interval.** In this method a is best chosen as the **class mark** of one of the classes in such a way as to make $d_i{}^1$ as small as possible.

The arithmetic mean is a **measure of central tendency** which summarizes the data. It lies between the least and the greatest variate in a distribution. The sum of the deviations from the mean is zero. The sum of the squared deviations about the mean is a minimum. The arithmetic mean should be used as the **average** unless special circumstances indicate the use of some other measure of central tendency. In a positively skewed distribution usually the mean is greater than the **median** which is greater than the **mode.** In a nega-

tively skewed distribution these measures of central tendency are in reverse order.

The mean, $\bar{X}$, of the combination of r sets with means $\bar{X}_1, \bar{X}_2, \cdots \bar{X}_r$ and numbers of variates $N_1, N_2, \cdots N_r$, respectively, is

$$\bar{X} = \frac{N_1\bar{X}_1 + N_2\bar{X}_2 + N_3\bar{X}_3 + \cdots + N_r\bar{X}_r}{N_1 + N_2 + \cdots + N_r}.$$

The **standard deviation** of the mean, commonly called the standard error of the mean, $\sigma_{\bar{X}}$, measures the **variability** of sample means drawn from a **population** with **variance** σ^2, $\sigma_{\bar{X}} = \frac{\sigma}{\sqrt{N}}$, where N is the number of variates in the sample mean. An unbiased estimate of σ^2 is given by $\frac{N\sigma_S{}^2}{N - 1}$, where $\sigma_S{}^2$ is the variance in a sample. (L.A.A.)

ARITHMETIC PROGRESSION. An arithmetic progression is a succession of **numbers** such that each member of the set differs from the preceding one by a constant called the common difference. The term "arithmetic progression" is often abbreviated A.P.

There are two fundamental formulae for arithmetic progressions—one for the general term and one for the sum of any number of terms.

The general term or n^{th} term of an arithmetic progression whose first term is a and whose common difference is d is given by the formula

$$l = a + (n - 1)d.$$

The sum of the first n terms of this arithmetic progression is given by

$$S = \frac{n}{2}(a + l).$$

The terms of an arithmetic progression between **the** first and last terms are called arithmetic means.

The arithmetic mean of two numbers is the middle term of an arithmetic progression whose first and last terms are the given numbers; it is given by half the sum of the given numbers. The arithmetic mean of two numbers is the same as the so-called arithmetic average of the two numbers. (L.L.S.)

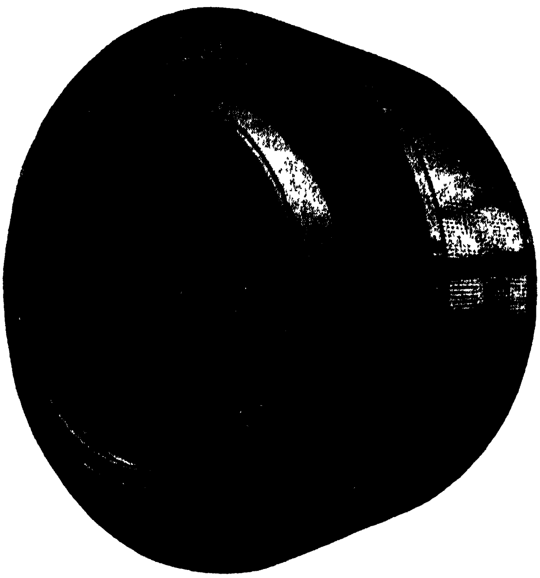
ARIZONITE. A term proposed by Spurr and Washington in 1917 for a **dike** rock largely composed of **quartz** but with an appreciable amount of **orthoclase.** (R.M.F.)

ARKOSE. Arkose is a relatively coarse-grained feldspathic **sandstone,** derived from the rapid disintegration of granite or other **feldspathic** rock. It is characterized by its content of fresh, unaltered, euhedral **feldspar.** The term was proposed by Brongiart in 1823, and has been in constant use ever since. Arkose is an important type of sediment especially in relation to the study of **unconformities, Paleoclimatology, "fossil" soils,** etc. (R.M.F.)

ARM. An extended lobe or appendage of a body. The radiating lobes of the starfish are called arms or rays and the term is also applied to the branches of the **lophophore** in **brachiopods** and to other special structures. Its most familiar use is in application to the pectoral appendages of **vertebrates** when freed from the usual functions of support and locomotion, as in man and the other primates. In anatomy the term is restricted to the region from the shoulder to the elbow, to distinguish it from the forearm. In most of these species the arms are used for locomotion through the trees and some are still quadrupedal on the ground, but even in these species the arms can be used to some extent for handling objects. (A.W.L.)

ARMADILLO. Mammalia, Edentata. Burrowing animals with many bony plates in the skin which form a more or less complete armor when the animal rolls up. Several species occur from Argentina northward through South America and one, the 9-banded armadillo, is found in Texas. They range in size from the 5-in. pichiciago to the 3-ft. giant armadillo. (A.W.L.)

ARMATURE. The armature is one of the two essential parts of the dynamo electric machine. In a generator, the armature is the winding in which **electromotive force** is produced by magnetic induction. In the **motor** armature, conductors carry the input current which, in the presence of a **magnetic field,** produces a **torque** and effects the transmission of electrical into mechanical energy. In d-c machines it is the rotor, but the a-c armature may be rotor or stator. Larger size synchronous machines always have stationary armatures. The reluctance of the magnetic circuit to the **flux** of which the conductors of the armature must cut in order to generate electric energy, is decreased by providing a core of soft iron or steel, on the surface of which the conductors are embedded in slots suitably provided in the core. The armature windings of a d-c generator are terminated at the segments of a **commutator,** by means of which the alternating e.m.f.'s induced in the armature are rectified and transferred by **brushes** from the moving rotor to stationary terminals. The conductors must be separately insulated, as must be also the commutator segments, and must be well braced and anchored in their slots to resist the electromagnetic and mechanical forces which tend to displace them. (F.T.M., L.R.Q.)



Armature of a d-c generator.

ARMATURE REACTION. This term refers to the reaction of the magnetic field produced by the current flowing in the armature conductors upon the main magnetic field of a dynamo machine. The result is a distortion of the magnetic field, the extent depending upon the reluctance of the magnetic circuit, the arrangement of the armature windings, the type field structure, and the phase angle between the armature voltage and current. In d-c machines the effect is to increase the flux at some pole tips and decrease it at others, while in a-c machines the effect depends upon the field structure and the phase angle of the armature current and voltage. The flux may be distorted as in the d-c machine, it may be changed in magnitude but undistorted

in wave form or it may be changed in magnitude and shifted in position with respect to the field windings. Armature reaction is an important factor in the speed and voltage regulation of the machines. (L.R.Q.)

ARMY-WORM. Insecta, Lepidoptera. An economically important **caterpillar,** ***Cirphis unipuncta,*** named from its habit of migrating from field to field in large numbers. When severe outbreaks occur these insects completely strip fields of grain of all kinds. When migrating they are trapped in barrier ditches dug around the fields to be protected. They are also killed by poison baits. (A.W.L.)

ARNICA. Composite Family.

AROIDS. A large group of **monocotyledonous** plants, mostly tropical, having a characteristic flower habit. The numerous small inconspicuous flowers are borne on a fleshy stalk or spadix, which is surrounded, more or less completely, by a large, expanded, often brightly colored **bract** called a spathe. The spadix and spathe together are often but incorrectly considered to be the flower of the plant. The aroids are perennial plants, generally having tubers or **rhizomes** from which rise large leaves. Many tropical members are climbing plants. Well-known species are the Skunk Cabbage, whose foul-scented flowers appear so early in the spring, the Jack-in-the-Pulpit, and the wild arum, *Calla palustris,* of cold swamps, as well as the Sweet Flag, *Acorus Calamus,* of the marshes. The cultivated Calla Lilies are all aroids and not lilies at all; some of them are delightfully fragrant. On the other hand, in species of *Amorphophallus,* which are sometimes seen in collections of cultivated plants, the vile odor of the flower structure prevents them from becoming popular; the spathe and spadix of some of them are of gigantic size. In the tropics several species of *Colocasia* are cultivated for the edible rhizomes which appear under the name of dasheen or taro. (R.M.W.)

AROMATIC HYDROCARBONS. Benzenoid Hydrocarbons.

AROMATIC OILS. Volatile Oils.

ARRAY. A row or a column in a correlation table, or in an **analysis of variance** table. (See **Directional Antenna.**) (L.A.A.)

ARRHYTHMIA. Any variation in the normal **rhythm** of the **heart.** (See **Pulse.**) (R.S.M.)

ARROW WORM. Small marine animals sometimes classified with the **annelid** worms but more often included in the separate phylum **Chaetognatha.** (A.W.L.)

ARROYO. This term is applied to dry stream channels with nearly vertical walls and flat bottoms which are characteristic of semi-arid regions. They may suddenly become filled with torrential waters after heavy rains. The word arroyo is of Spanish origin. (E.S.C.S.)

ARSENIC. Symbol: As. Atomic number: 33. Atomic weight: 74.91. Density: gray 5.73; black 4.7; yellow 2.0. Hardness: 3.5. No isotope, but of single atomic form: 75.

Arsenic is a gray metal, brittle; sublimes on heating; is unchanged in dry air but a film of oxide is formed in moist air; heated in air at 180° C. forms arsenic trioxide of the odor of garlic, poisonous; insoluble in **hydrochloric acid** but soluble in concentrated **nitric** or concentrated **sulfuric acid** to form arsenic acid; soluble in hot **sodium** hydroxide solution; heated with chlorine forms arsenic trichloride; heated with metals forms metallic arsenides. When arsenic is heated in a tube and the vapor cooled (1) slowly (that is, in the hot part of the tube) black arsenic is formed, and this form is converted into the gray at 360° C., (2) rapidly (that is, in the cold part of the tube) yellow arsenic is formed, and this form is quickly converted into the gray by the action of light. Yellow arsenic is soluble in **carbon disulfide.** Arsenic element was discovered by Schröder in 1649.

Arsenic occurs as arsenide in many sulfide ores, e.g., of zinc, iron, cobalt, nickel, and as the mineral sulfides, **realgar** (arsenic monosulfide, AsS), red colored, **orpiment** (arsenic trisulfide, As_2S_3), yellow-colored—these two minerals when powdered are used as paint pigments —**arsenopyrite,** mispickel (iron arsenosulfide, FeAsS). The primary arsenic-containing material is arsenious oxide obtained by separation from roaster or smelter flue gases, and is most largely produced in Montana and Utah. Arsenic is obtained as a sublimate by heating the oxide with carbon. The use of free arsenic is practically limited to the manufacture of chilled shot—addition of arsenic (0.1%) lowers the melting point and increases the surface tension of lead so that chilling of the liquid drops yields spherical shot.

Acids: Arsenious acid is the name sometimes applied to solutions of arsenious oxide, but the acid has not been isolated; arsenic acid ($H_3AsO_4 \cdot \frac{1}{2}H_2O$), white solid, soluble, by heating arsenious oxide with **nitric acid** and crystallization, (1) ortho-arsenic acid (H_3AsO_4 or $As_2O_5 \cdot 3H_2O$), heating these crystals at 100° C., (2) pyro-arsenic acid ($H_4As_2O_7$ or $As_2O_5 \cdot 2H_2O$) by heating ortho-acid to 140°–180° C., (3) meta-arsenic acid ($HAsO_3$ or $As_2O_5 \cdot H_2O$) by heating pyro-arsenic to 200° C. While salts of these acids are known the only hydrates identified are $As_2O_5 \cdot 4H_2O$ and $3As_2O_5 \cdot 5H_2O$.

Arsenates: **Sodium** arsenate, sodium ortho-arsenate, trisodium arsenate ($Na_3AsO_4 \cdot 12H_2O$); sodium dibasic arsenate, disodium hydrogen arsenate ($Na_2HPO_4 \cdot 7H_2O$); sodium monobasic arsenate, sodium dihydrogen arsenate ($NaH_2AsO_4 \cdot H_2O$) and the corresponding potassium salts are white soluble solids; the former used as a mordant in textile dyeing and printing; **silver** arsenate (Ag_3AsO_4), reddish-brown precipitate, by reaction of silver nitrate solution and sodium arsenate solution, soluble in nitric acid or ammonium hydroxide; **magnesium** ammonium arsenate ($MgNH_4AsO_4$), white precipitate, by reaction of sodium arsenate solution and "magnesia mixture"—a reagent made by adding ammonium chloride to ammonium hydroxide and then to magnesium salt solution without the formation of a precipitate of magnesium hydroxide. Many pyro-arsenates and meta-arsenates have been described.

Arsenides: Metallic arsenides are formed (1) by heating the finely powdered metal with arsenic, e.g., iron arsenide ($FeAs_2$), (2) by reaction of the metallic salt solution and arsine, e.g., copper arsenide (Cu_3As_2).

Arsenites: Sodium arsenite, sodium meta-arsenite ($NaAsO_2$) and potassium arsenite ($KAsO_2$) are white soluble solids, and the former is used as an insecticide, a weed killer, and poison; silver arsenite, silver ortho-arsenite (Ag_3AsO_3), yellow precipitate, by reaction of sodium arsenite solution and silver nitrate solution, soluble in nitric acid or ammonium hydroxide; copper arsenite ($Cu(AsO_2)_2$), green solid, used as the arsenite-acetate as an insecticide and poison ("Paris green").

Arsine: See Hydrides.

Chloride: Arsenious chloride, "butter of arsenic" ($AsCl_3$), colorless liquid, boiling point 130° C., by reaction of arsenic-containing solutions with concentrated hydrochloric acid, and applied in the analysis of arsenic containing substances by distilling in a current of hydrogen chloride gas below 108° C. (**Germanium** tetrachloride is volatilized similarly.)

Hydrides: Arsenic hydride, arsine (AsH_3), colorless gas, garlic odor, very poisonous by reaction of a solution of any arsenic containing material with (a) a metal, e.g., zinc, magnesium for iron, and hydrochloric or dilute sul-

furic acid, or (b) a metal, e.g., zinc or aluminum, and sodium hydroxide solution. Arsine (1) when heated in a glass tube yields a metallic mirror of arsenic, (2) when passed into a solution of silver nitrate yields black precipitate of metallic silver and arsenious acid solution, (3) when passed over solid silver nitrate yields yellow solid ($Ag_3As\cdot 3AgNO_3$), (4) when passed over solid mercurous chloride or solid mercuric chloride, or into mercuric chloride solution yields brown solid mercurous arsenide, (5) when passed into copper sulfate solution yields black precipitate of copper arsenide (Cu_3As_2). The formation and detection of arsine are important in estimating small amounts of arsenic (Marsh's test, Gutzeit's test, Fleitmann's test). Arsine burns in air with a bluish flame forming arsenious oxide and water; is unchanged in solution of sodium hydroxide; arsenic dihydride (As_2H_2), brown solid, formed by partial burning of arsine, and by electrolysis of water using an arsenic cathode.

Oxides: Arsenious oxide, arsenic trioxide, "white arsenic," "arsenic" (As_2O_3), white solid, moderately soluble, sublimes at 218° C., soluble in alkalis to form arsenites, known in three forms, (1) octahedral, by rapid cooling of the vapor (that is, in the cold part of the condenser), density 3.63, (2) amorphous, by slow cooling of the vapor (that is, in the hot part of the condenser), density 3.74, melting point 200° C., and three times as soluble as octahedral, (3) monoclinic (needle-like crystals), by heating either of the above forms to 200° C. for a long time, density 4.15. The oxide is formed by burning arsenic or arsenides in air. By-product in the fumes of metallurgical smelters. Used as insecticide, rat poison, preservatives of skins and hides, and as the principal source of arsenic compounds. Freshly precipitated ferric hydroxide absorbs arsenious oxide, and is used as an antidote in cases of arsenic poisoning.

Sulfides. Arsenic monosulfide, arsenic disulfide (AsS or As_2S_2), red solid, by heating arsenious oxide and **sulfur,** melting point 307° C., used with sulfur and **potassium** nitrate in pyrotechnic powder for producing blue flame; arsenious sulfide, arsenic trisulfide (As_2S_3), (1) yellow precipitate by reaction of solution of arsenite and hydrogen sulfide, in the absence of acid, alkali or salt the precipitate does not coagulate but large quantities may be formed in yellow **colloidal** solution, insoluble in concentrated hydrochloric acid and formed in its presence, soluble in sodium or ammonium sulfide to form thioarsenite, (2) yellow solid by distilling arsenious acid and sulfur from a retort. Used as a paint pigment but the color is not permanent in the light; arsenic sulfide, arsenic pentasulfide (As_2S_5), yellow precipitate, by reaction of solution of arsenate and hydrogen sulfide (in the presence of concentrated hydrochloric acid).

Numerous organic compounds containing arsenic ("arsenicals") have been prepared; among these are salvarsan, neosalvarsan, atoxyl.

Nitric acid readily transforms all arsenic-containing substances (other than arsenic acid) to arsenic acid.

Solutions of arsenic-containing substances, when boiled with **hydrochloric acid,** deposit a gray film on a bright strip of copper. This film of arsenic or copper arsenide, when dried and heated in air in a glass tube, sublimes as arsenious oxide, tiny white crystals.

Arsenic in any form may be detected by the Marsh or Gutzeit tests. Arsenites give a yellow precipitate with silver nitrate solution; arsenates a chocolate-brown precipitate. (R.K.S.)

ARSENOPYRITE—MISPICKEL. The mineral arsenopyrite is a sulfarsenide of iron corresponding to the formula FeAsS. A variety in which some of the iron is replaced by cobalt is known as danaite. It crystallizes in the **orthorhombic system.** Its hardness is 5.5–6; specific gravity, 5.9–6.2; luster, metallic color, silvery-white to steel-gray, but usually with a yellow to gray tarnish; streak, black. Arsenopyrite is a common mineral with tin and lead ores and in pegmatites, probably having been deposited by action of both vapors and hydrothermal solutions. It is a widespread mineral, well known deposits occurring in Austria, Saxony, Switzerland, Sweden, Norway; Cornwall and Devonshire, England; Bolivia. In the United States at Roxbury, Connecticut; Franklin, New Jersey; Paris, Maine; Emery, Montana; and Leadville, Colorado. Danaite was first found in Franconia, New Hampshire, by J. D. Dana, for whom it was later named. Mispickel is an old German term whose exact derivation is unknown. (E.S.C.S.)

ARSPHENAMINE. **"Salvarsan."** An **arsenic** preparation given intravenously in the treatment of **syphilis, yaws, Vincent's Angina** (trench mouth), etc. It was first discovered by Ehrlich and is also known as "606." It is a yellowish powder, unstable when exposed to the air. Its chemical name is Diaminodihydroxyarsenobenzene dihydrochloride $(OH \cdot C_6H_3(NH_2 \cdot HCl)As)_2$. **Neoarsphenamine** is now more commonly used because it is less toxic and more soluble.

Marpharsen (arsenoxide) is believed to be the form in which arsphenamine is active in killing spirochetes in the body. Since only 1/10 of injected arsephenamine forms arsenoxide, the dose of mapharsen is 1/10 that of arsphenamine. This decrease in dose diminishes toxic reactions. In addition, mapharsen is stable in air and is more easily prepared than arsphenamine.

Silver arsphenamine is arsphenamine with silver, combining the therapeutic properties of both. It is rarely used. (D.M.H.)

ART MOBLIER. **Paleontology of Man.**

ARTEMISIA. Compositae. Many of the 280-odd species of Artemisia have been cultivated or used by man. Southernwood, *Artemisia Abrotanum,* is cultivated in gardens for its delicate foliage and aromatic odor. Another and a homely species, *Artemisia vulgaris* or Mugwort, is also frequently cultivated, as is *Artemisia Absinthium,* a native European perennial plant. All contain volatile oils. That from *Artemisia Absinthium,* oil of wormwood, is a powerful drug, capable of causing violent convulsions when taken even in small doses. It is used to flavor the alcoholic beverage absinthe, a liquor capable of producing much the same effects as the drug. The sage-brushes of the western United States are all species of Artemisia; like other species they contain an abundance of aromatic oil. From *Artemisia dracunculus,* a European species, tarragon is obtained. This is used as a condiment, and for flavoring vinegar and mustard. (R.M.W.)

ARTERIOSCLEROSIS. (Hardening of the **arteries.**) This term is used clinically to describe several varieties of pathological degenerative changes in the arteries. The large and medium-sized arteries show degeneration, deposition of fat and finally calcification. The small arteries (arterioles) show hyaline degeneration, replacement of normal tissue with a transparent acellular substance. The latter condition is almost always found in those who have had high blood pressure or **hypertension,** while the former condition may or may not be seen in hypertensives. Both types of arteriosclerosis occur most commonly after the age of 50. The symptoms due to this condition vary with the organs or structures involved.

The cause of arteriosclerosis is not known. Factors such as heredity, increasing age, and hypertension seem to contribute to its development. Diabetics are thought to be especially prone to develop arteriosclerosis.

The condition may be widespread throughout the body without producing any symptoms, but by local impairment of the blood supply, it may damage any organ. The heart, brain, kidneys and extremities are most frequently involved.

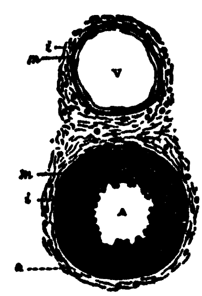
In the heart, arteriosclerosis commonly causes **angina pectoris, coronary occlusion, arrhythmias,** and **heart failure. Kidney** involvement results in decreased function which may terminate in **uremia.** Marked cerebral arteriosclerosis may be manifested by senile **psychoses,** or by occlusion of a cerebral vessel, **apoplexy,** ("a stroke") and hemiplegia. In the extremities, arteriosclerosis may cause cramps, numbness and tingling, and in advanced cases, **gangrene.**

The treatment of the disease is symptomatic, as well as being directed toward improvement of the circulation to the various organs involved.

The prognosis depends upon the organs affected. Arteriosclerosis causes the death directly or indirectly of the majority of individuals who live beyond the age of 60 years. (D.M.H.)

ARTERY. A vessel leading away from the heart. (See **Circulatory System.**) (A.W.L.)

ARTESIAN WELL. **Ground Water. Hydrology.**



Transverse section through a small artery and vein, showing the relative difference in the thickness of their walls. *A,* artery showing *i,* the endothelial lining which with the thick layer of elastic tissue next to it constitutes the *intima.* The endothelial cells appear thick because the artery is contracted. *m,* the circular muscular coat or *media* constitutes the chief part of the wall of the vessel Outside this is *a,* part of the outer coat or *adventita.* *V,* vein showing *i,* a thin endothelial membrane, *m,* a few circular muscle cells. (*From Kimber and Gray, Textbook of Anatomy and Physiology, Macmillan & Co*)

ARTHRITIS. An acute or chronic **inflammation** of a joint. There are many varieties of the disease most of which fall into one of the four major types. 1. Atrophic or rheumatoid arthritis. 2. Hypertrophic or osteoarthritis. 3. Arthritis associated with acute bacterial infection. 4. The arthritis of **rheumatic fever, gout,** and certain systemic diseases, form a miscellaneous group.

Atrophic or rheumatoid arthritis (chronic infectious arthritis, arthritis deformans) is characterized by chronic inflammatory changes in the joints, and atrophy of the bone and surrounding musculature. Its etiology is unknown but certain features are thought to suggest an infectious element. The disease affects the whole organism, and such manifestations as weight loss, fever, **leukocytosis** are common. Women are attacked more often than men. The average age of onset is 30–35 years. Usually one joint alone is affected in the beginning, the metacarpo-phalangeal and phalangeal joints of the fingers being especially prone to develop fusiform deformities. In some cases the onset is acute and involves many joints at once. The course may be a mild one with frequent remissions, or there may be steady progression to multiple joint involvement and eventual crippling deformity. The treatment is not specific; general supportive measures—diet, rest, physiotherapy, prevention of contractures—are all important. Of the many drugs employed, gold salts intramuscularly have given the most promising results.

Hypertrophic osteoarthritis is a degenerative joint disease, common to almost all individuals in later life, its onset being as a rule in the 5th or 6th decades. It is characterized by degenerative changes in the joint cartilage with dense bony overgrowth in the form of spurs at

the joint surface. The joints most frequently involved are fingers, knees, hips and vertebrae. The etiology is unknown, but trauma and excessive weight are predisposing factors. Treatment is symptomatic. The disease progresses gradually and may be attended by considerable joint pain, but deformity and serious loss of function are very rare.

The arthritis of acute infections is sometimes of the suppurative variety, joint infections with hemolytic streptococci or staphlyococci, which are secondary to penetrating wounds, or to a **septicemia** with these organisms. Arthritis also appears as a suppurative complication of **tuberculosis, pneumonia, scarlet fever, gonorrhea,** meningococcic **meningitis** and **typhoid fever.** In scarlet, meningococcus meningitis, brucellosis and **dysentery,** pain, swelling and sterile joint effusions may also occur.

The arthritis of **rheumatic fever** is characteristically fleeting and migratory, and leaves no permanent damage. **Gout** is a systemic disease of unknown etiology with paroxysmal attacks of arthritis as its chief manifestation. (D.M.H.)

ARTHROBRANCHIAE. **Gills** attached to the joint membranes of certain **crustaceans.** (A W.L.)

ARTHRODIRE. **Fossil Fishes.**

ARTHROPODA. The largest and most diversified division of the animal kingdom, including **crustaceans,** horseshoe crabs (see **Xiphosura**), **insects, scorpions, spiders, centipedes,** millipedes (see **Diplopoda**) and other forms.

This phylum is characterized by the following structures: 1. The body is **triploblastic** and metameric (see **Metamere**), and is further subdivided into regions of which there may be a maximum of three: **head, thorax,** and **abdomen.** 2. Supporting structures are developed from the integument and constitute an exoskeleton made up of plates connected by flexible regions for freedom of movement. 3. Jointed appendages, fundamentally a pair to a segment, give the phylum its name. 4. The **circulatory system** is a combination of tubes and open spaces; the coalescence of the latter to form a haemocoel is accompanied by extreme reduction of the coelom. 5. The **eyes** are of a form peculiar to the group. 6. The **respiratory system** consists of air tubes or **tracheae,** of gills, or of **lung books** formed of leaf-like expansions of the body wall located in a cavity narrowly open to the exterior. Some species have no special respiratory organs.

The phylum is divided into several classes as follows:

Class **Onychophora.** Soft-bodied worm-like animals. Commonly called **Peripatus,** the name of one genus.
Class **Tardigrada.** The bear animalcules.
Class **Pentastomida.** Parasites known as pentastomids or linguatulids.
Class **Pycnogonida.** The sea-spiders.
Class **Crustacea.** **Crabs, lobsters, crayfishes, shrimps, barnacles, woodlice** or pillbugs, and other forms.
Class **Xiphosura.** The king crab or horseshoe crab. Also given the name Palaeostraca.
Class **Arachnida.** **Spiders, mites, ticks, scorpions,** etc.
Class **Diplopoda.** The millipedes.
Class **Pauropoda.** Rare forms allied to the preceding.
Class **Chilopoda.** The **centipedes.**
Class **Symphyla.** Rare forms allied to the preceding.
Class **Insecta.** The insects. (See also **Invertebrate Paleontology.**) (A.W.L.)

ARTICHOKE, GLOBE. *Cynara Scolymus.* **Composite Family.**

ARTICHOKE, JERUSALEM. *Helianthus tuberosum.* **Composite Family.**

ARTICULATION. This term has three common meanings. 1. A **joint,** such as the knee or elbow, etc. 2. Enunciation. 3. In dentistry, the contact of the teeth. (R.S.M.)

ARTIFACT. **Paleontology of Man.**

ARTIFICIAL HORIZON. **Sextant.**

ARTIFICIAL LINE. An artificial line is an electrical network consisting of **resistance, inductance** and **capacitance** so connected that it has the same characteristics (electrical) as the actual transmission **line.** Sometimes where the artificial line is not required to duplicate exactly the actual line the inductance or capacitance may be omitted. Such a line is very valuable for making laboratory tests as it makes possible connection at points corresponding to many miles of actual line. Artificial lines are also used widely in telephone and telegraph practice to balance actual lines to give desired operating characteristics in bridge type circuits. (L.R.Q.)

ARTIFICIAL PNEUMOTHORAX. **Tuberculosis** treatment. (R.S.M.)

ARTIODACTYLA. Hoofed animals which retain an even number of toes, the axis of the foot passing between the third and fourth digits. The species included are the **pigs, cattle** and related species, **antelopes, camels, hippopotami, giraffes, deer,** and some less familiar forms. The group constitutes an order of the class **Mammalia,** often called the even-toed **ungulates.** (A.W.L.)

ARYL. **Radical** of benzenoid **hydrocarbon.**

ASAFETIDA. *Ferula fetida.* Umbelliferae. Asafetida is a perennial herb found in Persia and Afghanistan. It grows 6–10′ tall, and bears large compound leaves of bluish-green color, and large compound umbels of pale yellow **flowers.** The roots contain a milky juice which oozes out when they are cut, and hardens to a gummy substance bitter in taste. This substance, although extremely foul-smelling, is much used in the East and in France as a condiment. In small quantities its unpleasant odor is not apparent as, for instance, in "Worcestershire" sauce. As a drug, asafetida was earlier supposed to stimulate the nervous system. (R.M.W.)

ASBESTOS. This is the popular name for several fibrous minerals used for fireproofing and heat insulating material. Most of the commercial asbestos is a variety of **serpentine** called chrysotile. A fibrous kind of **amphibole** is called asbestus. Both terms asbestos and asbestus are derived from the Greek word meaning unquenched, which was applied to minerals that resisted fire. (E.S.C.S.)

ASCARIS. Nemathelminthes, Nematoda. *Ascaris.* Paratic roundworms of relatively large size found in the intestines of man and other animals. (A.W.L.)

ASCENT OF SAP. All of the organs of any terrestrial plant are dependent for their existence upon water absorbed from the soil. This water, which always contains traces of solutes and hence is often referred to as sap, moves in a generally upward direction through the plant. In some of the tallest known specimens of redwood trees (*Sequoia sempervirens*) the sap must ascend to heights exceeding 350′ if the topmost branch is to be kept supplied with water. The upward movement of sap in plants occurs in the xylem, which in trees and shrubs corresponds to the wood. In the trunks or

larger branches of trees sap movement is confined to a few of the outermost annual rings of wood. Sap movement occurs only through the vessels and tracheids of the woody tissue.

The earlier theories of the upward movement of sap in plants mostly invoked some vaguely conceived vital activity of the cells as furnishing the motive power for sap movement. Although the vessels and tracheids through which the water moves are dead, they are always in intimate contact with living wood parenchyma and wood ray cells and it is not inconceivable that these cells might in some way motivate the upward movement of sap. However, such theories receive very little support at the present time.

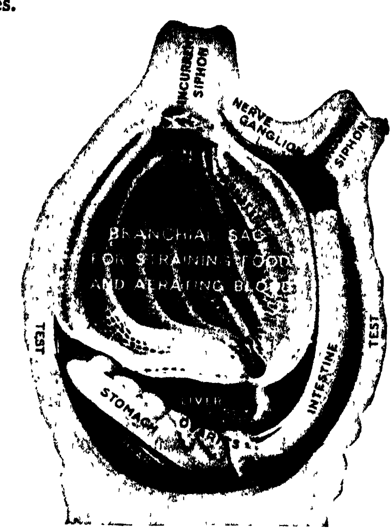
It is a common observation that sap may flow from the severed stems of many kinds of plants and that this flow ("bleeding") may continue for some time. This exudation of sap results from a pressure originating in the root called *root pressure,* and the exuded sap comes from the xylem tissues. Root pressures are also present in intact plants. For several reasons, however, root pressure can be considered only a secondary mechanism of water transport in plants. In the first place there are many species in which the phenomenon does not occur. In the second place the magnitude of measured root pressures seldom exceeds two atmospheres which could not cause a rise of sap of more than about sixty feet. In the third place known rates of sap flow under the influence of root pressure are inadequate to compensate for many known rates of **transpiration.** And finally, in woody plants at least, root pressures are usually present only in the early spring; during the summer period when transpiration rates and hence rates of sap movement are greatest, root pressures are negligible or non-existent.

The principal mechanism motivating the ascent of sap in plants is thought by most present day botanists to be dependent upon the property of *cohesion* (see **Adhesion**) in water. The cohesive forces between water molecules are very great. The evaporation of water from the mesophyll cells of the leaf during transpiration results in the movement of water molecules into these cells from the xylem (water-conducting tissue) of the veins. The xylem of the leaves is continuous with that of the stems which in turn is continuous with that of the root system out almost to the very tip of every rootlet. The water is apparently present in the cells and vessels of the xylem as continuous thread-like columns. As water molecules pass out of these water columns into the mesophyll cells the threads of water become taut throughout the plant. Eventually a tension of considerable magnitude may be set up in them which is transmitted from the top to the bottom of the plant. The water columns can sustain this tension only because of the high cohesive force of water. When the water in the xylem of the younger roots passes into a state of tension movement of water from the root cells into the xylem cells is induced. Loss of water from the root cells in turn causes absorption of water from the soil. Movement of water through the entire plant is thus brought about. Whenever transpiration rates are appreciable water does not, as a rule, enter the lower ends of the xylem ducts from adjacent root cells as fast as it passes from the upper ends into the mesophyll cells, hence the water is continuously under tension during periods of rapid transpiration and upward movement of sap. Calculations indicate that a cohesive force of between 30 and 50 atmospheres would be adequate to permit translocation of water to the very top of the tallest known trees by this mechanism. Experimentally determined values of the cohesive force of water are in excess of 300 atmospheres. (B.S.M.)

ASCHHEIM-ZONDEK TEST. A laboratory test which indicates the presence of pregnancy. During pregnancy the urine contains an ovary-stimulating or gonadotropic **hormone** produced by the chorionic cells of the **placenta.** This hormone is similar to the gonadotropic hormone of the anterior **pituitary** and is called A.P.L., or anterior-pituitary-like hormone. When urine from a pregnant woman is injected into immature mice or virgin rabbits, characteristic changes are produced in the animal's ovaries by the action of A.P.L. hormone. A positive test is obtained with urine excreted 8 days after the first missed menstrual period, when it is impossible to make a diagnosis by physical examination.

The Aschheim-Zondek test is also positive in pathological conditions in which there is a retention of placental tissue after delivery. (D.M.H.)

ASCIDIACEA. Chordata, Tunicata. The **tunicates,** sea squirts, or ascidians (**Ascidiacea**), constituting a class of the subphylum **Tunicata.** They begin life as **larvae** which resemble tadpoles in form and later become **sessile** animals invested in a covering called the test or **tunic.** Some species are solitary and others form colonies.



Internal anatomy of the adult sea squirt. (*American Museum of Natural History.*)

The class contains four orders:

Order Krikobranchia. Sessile colonial forms. Body elongate, usually with transverse constrictions.

Order Dictyobranchia. Mostly solitary species. Body without constrictions. Tunic translucent.

Order Ptychobranchia. Solitary or colonial. Tunic opaque.

Order Pyrosomida. Colonial, the entire colony free-swimming. (A.W.L.)

ASCITES. The presence of free fluid in the abdominal cavity, popularly called dropsy of the **abdomen.** Two causes of the condition are known; one is the obstruction of the venous return to the **heart** in diseases of the heart, **liver** and **kidney,** and the other is local inflammation of the **peritoneum,** as in tuberculous peritonitis. It is also seen when **cancer** has metastasized to abdominal structures and to the peritoneum. (R.S.M.)

ASCOMYCETES. Sac Fungi. Fungi. Many of the 40,000 species of **fungi** comprising the Ascomycetes are very common plants, but few are conspicuous. The great part of the species are small, often minute, while a few attain heights of 3 or 4″, with a diameter of 1–2″. Occasional individuals are even larger. All are characterized by the **ascus,** or spore-sac, commonly an elongate cylindrical body containing eight **spores.** In some species the ascus is spherical, or short cylindrical, while the number of spores may vary from two to many. Usually the asci are grouped together in a dense layer,

called the hymenium. This may be composed entirely of asci, or may contain in addition numerous slender sterile filaments, called paraphyses. In some cases at least it seems the function of the paraphyses to protect the asci, since the outer tip of each paraphysis is a flattened cap which partially covers the ascus. Ascomycetes are found wherever suitable food-yielding materials exist. Many species are parasites, living on living plants; among these are species of great economic importance. Other species are saprophytes, wood-destroying species being particularly numerous.

The life-history of an Ascomycete comprises the very important but inconspicuous **mycelium** composed of slender branching septate hyphae which penetrate throughout the substratum, and extract from it nutrient materials which are elaborated and stored up within, and the fruiting stage in which the asci are formed. Two types of reproduction occur. One of these is the asexual type, in which asexual cells called conidia are cut off in various ways from the tips of hyphae, known as conidiophores. These conidia are single-celled spores which are disseminated by air currents. The other method of reproduction is sexual, and leads to the formation of asci. In *Pyronema confluens* this process has been carefully studied, and may be considered as typical in the main details for the process as it occurs in all the fungi of this class. The first step in this process is the formation of a multinucleate much-branched structure, which presently becomes septate. Some of the tips of this structure enlarge and become **oögonia,** called in this case ascogonia, while other tips become **antheridia.** From the oögonium a slender curved body called the **trichogyne** grows out. This is separated from the oögonium by a cross-wall. Since the oögonia and antheridia develop close together, the trichogyne comes in contact with the antheridium. All three bodies, oögonium, antheridium and trichogyne, are multinucleate. When the trichogyne comes in contact with the antheridium the walls between them at once break down, as does the wall between the trichogyne and the oögonium. The nuclei of the antheridium pass into the trichogyne, through it and into the oögonium. After this a new wall forms separating the trichogyne from a oögonium. In the oögonium the nuclei from the antheridium pair up with the nuclei of the oögonium, the nuclei of the trichogyne disintegrating early in the period of nuclear migration. Following the pairing of the nuclei in the ascogonium, coarse hyphae grow out from the latter. Into these the paired nuclei migrate. These coarse hyphae are the ascogenous hyphae, from which the **asci** eventually develop. In many Ascomycetes this process is considerably shortened, the acogenous hyphae arising directly from the mycelium, no sex cells being formed; while other species have sex cells but no fusion, the oögonium alone developing.

The life cycles of the various ascomycetes are remarkably uniform, suggesting that they are all derived from a common ancestor. Two different views are held by botanists as to what the ancestral form may have been. According to one group, they are derived from red **algae;** favoring this view is the very great similarity in the development of the ascogonium and that of the **carpospore** formation in the algae; another favorable point is the presence of the trichogyne and the behavior of the antheridial nuclei. On the other hand, the other group holds that the ancestors of the Ascomycetes are to be found in the Phycomycetes, basing this contention on the similarity of the Phycomycete sporagium and the ascus, the latter being merely a sporangium in which the number of spores has been greatly reduced, becoming stable at eight in most species.

Many members of this class of fungi are of great importance to man because of their destructive parasitic habit. A few species are of value as food, or in the production of foodstuffs, and other products used by man.

Among the injurious species may be mentioned the Chestnut Blight fungus, *Endothia parasitica,* a disease probably introduced from China at the beginning of the twentieth century. In China the native chestnut trees had developed immunity; this the American trees did not have, so the fungus, which attacks the cambial tissue, was particularly destructive, nearly wiping out the native chestnut trees in a few years. Another disease caused by an Ascomycete is the Brown Rot of stone fruits, caused by *Sclerotinia cinerea.* This fungus is particularly destructive in wet seasons. Often infected fruits become shriveled up and dry, in which condition they are known as "mummies." A large group of Ascomycetes are known as Powdery Mildews, because of the abundant conidiophores which are formed by the mycelium on the surface of the leaves of infected plants. Often these are so abundant as seriously to impair the functional efficiency of the leaf.

Another group of Ascomycetes contains species which are destructive and also those which are commercially of great value; these are the ubiquitous blue and green molds, species of *Aspergillus* and *Penicillium.* The destructive species attack foodstuffs everywhere, causing rotting and spoilage. Citrus fruits become covered with the bluish-green conidial masses; as does moist bread, pie crusts and many other foodstuffs. Species of the genus *Penicillium* give to Camembert and Roquefort cheese their characteristic properties. Other species of this group are the casual organisms for skin diseases of animals, including man. Another species of this genus, **Penicillium notatum,** is the source of the important drug, **penicillin.** Since discovery of the bactericidal effects of penicillin, commercial culture of this mold has been undertaken on a large scale. The organism is grown in sterile culture on a liquid medium consisting of water with suitable organic and inorganic substances dissolved in it. In some procedures, bottles a quart or more in capacity are used as containers for the cultures; in others, large deep tanks are used. When the tank culture method is used, forced aeration of the cultures is necessary; in the bottle culture method the mold grows only on the surface of the liquid and thus obtains an adequate supply of oxygen. When the cultures have reached a suitable stage of development the mold colonies are filtered out of the liquid medium and discarded. During the growth of the organism the penicillin diffuses out of, or otherwise escapes from, the cells and hence is present in the medium. The penicillin is removed from the medium by extraction with organic solvents and suitably concentrated for medical use.

Among the largest of the Ascomycetes are species of truffles and morels, which are considered by mushroom fanciers to be particularly finely flavored. Truffles are fruit-bodies of the order Tuberales, and grow entirely underground. This makes it a matter of some difficulty to find them. Since they do not lend themselves to artificial cultivation, truffles must be sought in their wild habitat. To aid in locating them, man has trained dogs and pigs to find them by their superior sense of smell.

Another important Ascomycete is the genus *Claviceps,* which is parasitic on many grasses, including several cereal grains. This fungus forms a hard black sclerotium which is known as ergot, and which completely replaces the grain in the infected flower. The sclerotia are poisonous to livestock, causing the animals which have eaten them to become emaciated and covered with sores; another result is abortion in females.

Another very important group of Ascomycetes is the **Yeasts.** (R.M.W.)

ASCON. **Porifera.**

ASCUS. The spore sacs characteristic of the **Ascomycetes.** typically each sac contains 8 **spores,** but many species are found where the ascus contains less than eight, while in others there are many more. The ascus develops from an ascogenous **hypha.** The latter is a septate hypha which grows in the form of a hook or

crosier. Each segment contains 2 nuclei; those of the apical hook-like segment divide simultaneously so that 4 nuclei are present. Septations cut off two of these nuclei, leaving a segment containing 2 nuclei which now fuse. The segment now elongates conspicuously and becomes the ascus while the fusion nucleus divides successively to form 8 nuclei which eventually become set off in 8 separate spores. Subsequent development of the segments cut off during ascus formation may lead to the development of additional asci from the same ascogenous hypha. (R.M.W.)

ASEPSIS. Absence of infection; sterility. (R.S.M.)

ASEXUAL REPRODUCTION. In asexual **reproduction**, a part of the parent organism, when removed, becomes an organism identical with the parent.

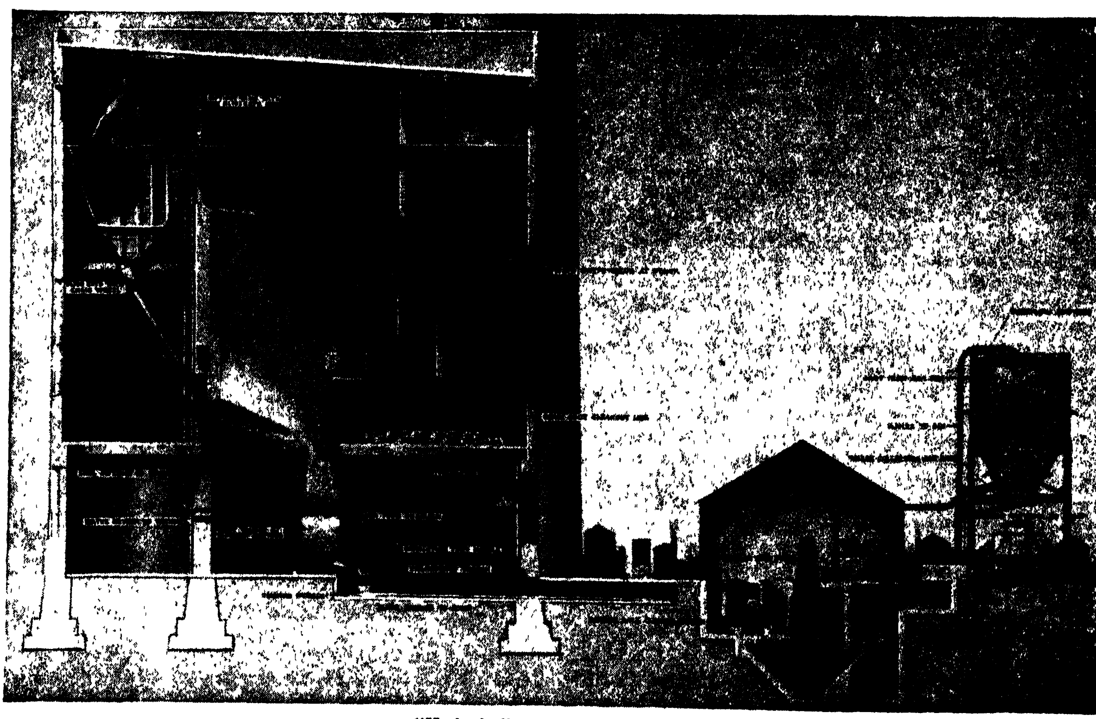
Different types of asexual reproduction are met in the different groups of plants, necessitating separate treatment. In green **algae** the characteristic method is by the formation of **zoöspores**, which are unicellular motile bodies formed from the **protoplast** of a single **cell.** Each zoöspore, after swimming around for a time, becomes quiet and grows to form a new individual of the parent type. In mosses and ferns, where a definite **alternation of generations** occurs, the unicellular **spores** which mark the end of one generation are an asexual means of reproduction. In flowering plants there are many methods of asexual reproduction, some of great importance to man. A common type is found in the strawberry, where long slender branches grow out from the short stem of the plant and take root at their tip. There a new plant forms. This reproductive structure is called a stolon. Many other plants produce similar branches which run along the surface of the ground (runners) or just beneath it (rhizomes), and send up one or more new plants from the nodes. Other plants, like the tiger lily, bear small buds in the axils of their leaves: the buds or bulblets are easily detached and readily grow to form new plants. Similar bulblets are formed at the base of many bulbs. Another very common method of asexual reproduction is through the formation of suckers, branches formed at the base of the parent plants, and gradually growing to replace them. Man propagates extensively date palms, pineapples, and bananas, for example, by means of suckers. The familiar potato tuber, the swollen tip of a rhizome, is another type of asexual reproduction which is of tremendous value to man.

All the methods so far enumerated are from the stem of the plant. However, any part of the plant may be a means of asexual renewal. Many plants are known which reproduce by means of the leaves. Several of these are now cultivated extensively as objects of beauty or of curiosity. For example, many of the ornamental begonias are readily propagated by leaves; in several ferns, little plants form on the leaf surface, from which they fall to the ground and grow. Less widely known but equally interesting are species of *Bryophyllum* and *Kalanchoë*. In the notches of the leaves of these plants, while still attached to the parent plant or after being severed therefrom, tiny plants readily form and grow.

Many plants readily root when cut up into segments. Most people are familiar with the habit of the willow twig of striking root and growing when stuck in the ground. Equally well known is the geranium cutting, which is merely a branch removed from the parent plant and placed in a favorable environment.

Asexual reproduction is of tremendous importance to man. New and improved forms of plants are constantly being made: by asexual means they are reproduced in the great quantities necessary for commercial use. Without such reproduction their formation in quantity would be practically impossible. (See **Grafting and Budding; Propagation.**) (R.M.W.)

ASH DISPOSAL. All coal has ash, and since coal is the principal fuel for domestic and industrial use, the disposal of ashes is an important and widespread activity. The combustion of coal in a **furnace** results in the accumulation in an ash hopper, or ash pit, of the refuse, which, with proper technical handling of the **combustion**, will be principally ash, but may in some cases contain up to 20%, by weight, of carbon in the unburned state. All the ash should be in the ash pit or hopper, but as a matter of fact, from 5% to 40% may leave the



"Hydrojet" ash-handling system.

furnace in the flue gases—carried in suspension. While little can be done about this in domestic and industrial practice, the large amount of coal consumed by public utility plants is potentially capable of discharging from the stack so much ash to the surrounding territory that endeavor is made to reduce the percentage of ash leaving with the gas, and to separate the residual ash from the gas and return it to the hopper.

Removal of ashes, and their disposal, is no simple problem because, first, the ash is dusty, hence irritating and annoying to handle; second, it may contain clinkers which must be broken before being given to any reasonably sized conveying equipment; and third, it is abrasive and will wear all conveyor parts in contact with it if there is any relative motion. Ash disposal systems are designed for continuous or intermittent operation, as the case may be, and consist of some means of removing ash from the furnace, loading it on a conveyor system, unloading from the conveyor to storage, and a means of disposing of stored ash. Ashes can be raked from ash pits to boiler room floors, and then shoveled into wheelbarrows or cars, or raked to gratings where they will fall into a conveying system. The large furnace will often be designed so that the ash may be handled by gravity directly from the hoppers to cars or conveying system.

Present-day conveying systems variously employ bucket conveyors, scrapers, pneumatic conveyors, steam jets, and water jets. Of these, one of the most popular as well as interesting methods is the hydraulic or water jet system. It is essentially a large-plant system, but has the advantage of being clean and dustless. When the hopper is to be emptied, the ashes are hydraulically undercut with an oscillating feed jet. The mingled ash and water flows into a trench along which the ash is carried under the influence of jets of water directed along the run of the trench. At the end of the trench the flow is dropped into a sump where the ash settles to the bottom and the sluicing water overflows to a clear well, ready for recirculation. A wet ash pump or clam shell bucket will deliver the wet ash to an elevated ash bin, where it can be further dewatered. The ultimate disposition of industrial ash is to railroad cars, trucks or barges. An important factor in ash disposal is its use as a building material, particularly to form cinder blocks. In all larger cities this demand places a potential value on ash, which must be considered in the choice of fuel-burning equipment, since the ash recovery from pulverized coal furnaces would have much less value than from stokers. (F.T.M.)

ASP. Reptilia, Sauria. A poisonous **snake** found in northern Africa and southwestern Europe, also called the southern viper and the Egyptian **cobra**. (A.W.L.)

Asp. (*N. Y. Zool. Soc.*)

ASPARAGUS. Liliaceae. A genus of about 125 species of liliaceous plants native to temperate and tropical regions of the Old World. All are characterized by having the leaves reduced to minute scales or bristles, while small, often very leaf-like branches called cladophylls function as leaves. The flowers are small, yellowish or white in color, and the fruit is a berry, often brightly colored. *Asparagus officinalis,* a native of the marshes of Europe, is the cultivated garden form with thick and fleshy young stems. Other species are widely grown for their delicate beauty, as the familiar Asparagus ferns, *Asparagus plumosus* and *Asparagus Spengeri* (which are not properly ferns at all), and the florist's smilax, *Asparagus asparagoides.* (R.M.W.)

ASPARAGUS BEETLE. Insecta, Coleoptera. An introduced European beetle, *Crioceris asparagi,* which is sometimes an important pest on asparagus. A related species, also introduced from Europe, is known as the 12-spotted asparagus beetle. They are held in check by hand-picking and by dusting plants with lead arsenate and lime. (A.W.L.)

ASPARAGUS STONE. **Apatite.**

ASPARTIC ACID. **Aldehydes, Ketones, and Related Compounds.**

ASPECT RATIO. Aspect ratio, one of the most important dimensions of a **wing,** measures its shape. It was long ago discovered that two wings of the same area, and built with the same **airfoil** section, did not have the same aerodynamic characteristics unless their area was of the same shape.

The term aspect ratio was then introduced to define this shape. The aspect ratio for a simple rectangular wing is the long dimension, i.e., the span perpendicular to the windstream, divided by the short dimension, the chord. However, many wings are not rectangular in plan form, and their aspect ratio is the span divided by the average chord. Since this average chord is the area of the wing divided by the span, it follows that for non-rectangular wings the aspect ratio is

$$Ʀ = \frac{\text{span}^2}{\text{wing area}}$$

In general, the larger aspect ratios are better from the aerodynamic standpoint, but poorer from the structural standpoint, since increasing the aspect ratio has the following results:

1. It decreases the drag.
2. It increases the rate of change of lift with the angle of attack.
3. It displaces the lateral center of pressure farther from the fuselage, and hence makes more difficult the problem of bracing rigidly the wing structure. (F.T.M.)

ASPECTS OF THE PLANETS. **Planetary Motion.**

ASPERGILLUS. **Ascomycetes.**

ASPHALT(UM). Asphaltum is a semi-solid mixture of several **hydrocarbons,** probably formed because of the evaporation of the lighter and more volatile constituents. It is amorphous, of low specific gravity, 1–2, with a black or brownish-black color and pitchy luster. Notable localities for asphaltum are the Island of Trinidad and the Dead Sea region, where Lake Asphaltites were long known to the ancients. (See also **Petroleum.**) (E.S.C.S.)

ASPHYXIA OR SUFFOCATION. This condition develops as a result of insufficient **oxygen** in the blood. The patient becomes **cyanotic** and unconscious, and if the causative factor continues, death results.

Local asphyxia is limited to a part of the body, and is due to an interruption of the blood supply to that part.

If total for any length of time **gangrene** of the part develops. (R.S.M.)

ASPIDOBRANCHIATA. GASTEROPODA.

ASPIDOCHIROTA. Holothuroidea.

ASPIRIN. Salycilates.

ASPLENIUM. Paleobotany.

ASS. Mammalia, Perissodactyla. Animals of several species related to the horses and zebras and belonging to the same genus, *Equus*. In addition to the domestic ass, *E. asinus,* wild asses are known in arid parts of Asia, from Persia to Mongolia, and in the deserts of northeastern Africa. (A.W.L.)

ASSASSIN-BUG. Insecta, Hemiptera. Any **bug** of the large predacious species constituting the family Reduviidae. (A.W.L.)

ASSOCIATION AND POLYMERIZATION; DISSOCIATION. The simplest formula for water is H_2O, **molecular weight** 18. By measurements of the **specific volume** and **surface tension** of liquid water at two different temperatures it is possible to estimate the molecular weight of this substance as liquid in terms of its molecular weight as vapor, and, consequently, the degree of association or dissociation, as the case may be. Water is estimated to be associated 2.7 to 2.0 times at 100° C.; 3.0 to 2.2 times at 60° C.; 3.6 to 2.4 times at 20° C. Dihydrol $(H_2O)_2$, and trihydrol $(H_2O)_3$, are believed to be the individual molecules concerned and to be present in proportions that vary with temperature. Substances believed to be associated as liquids to the degree of 2 to 3 times are: methyl **alcohol** (3.3), ethyl **alcohol** (2.5), **acetic acid** (3.2), **acetamide** (2.3), **benzamide** (2.2); and slightly: **acetone** (1.3), **phenol** (1.3). Normal liquids may be regarded as those whose molecules have a constant $\frac{\text{Molecular Weight} \times \text{Heat of Vaporization}}{\text{Absolute Temperature}}$ when observed under the condition of the same concentration of molecules in the vapor phase (Hildebrand, 1915), e.g., a concentration of 0.005 gram mol of vapor per liter. Such results are given in the following table:

NORMAL LIQUIDS	$\frac{\text{M W.} \times \text{Ht.Vap.}}{\text{T.}}$
Nitrogen	27.6 (at 55° Abs.)
Oxygen	27.6 (at 75° Abs.)
Chlorine	27.8 (at 194° Abs.)
Pentane	27.0 (at 256° Abs.)
Hexane	27.2 (at 286° Abs.)
Benzene	27.4 (at 298° Abs.)
Mercury	26.2 (at 560° Abs.)
Average	27 approx.

ASSOCIATED LIQUIDS	$\frac{\text{M.W.} \times \text{Ht.Vap.}}{\text{T.}}$
Water	32.0 (at 325° Abs.)
Ethyl alcohol	33.4 (at 307° Abs.)
Ammonia	32.4 (at 200° Abs.)

Of two substances having the same elementary percentage composition but multiple or sub-multiple molecular weights, the substance of higher molecular weight is known as the polymer of the substance of lower molecular weight. Polymerization is a marked property of certain groups of chemicals; e.g., olefin **hydrocarbons.** Amylene (C_5H_{10}) in the presence of sulfuric acid or zinc chloride polymerizes to $C_{10}H_{20}$, $C_{15}H_{30}$, $C_{20}H_{40}$. Monovinyl **acetylene** $(CH_2{:}CH{-}C{:}CH)$ is the polymer of acetylene $(CH{:}CH)$ and is made from the latter. **Formaldehyde** is polymerized spontaneously at ordinary temperature, and **acetaldehyde** upon the addition of a small percentage of hydrochloride acid, sulfuric acid, or zinc chloride.

Dissociation may be electrolytic or thermal. Electrolytic dissociation is discussed in articles on **Electrochemistry; Reactions Involving Recombination of Ions.** Thermal dissociation, an **equilibrium** phenomenon and not decomposition, is observed in the cases of such substances as the following:

Nitrogen tetroxide (N_2O_4) into nitrogen dioxide (NO_2)
  at 27° C., 80% N_2O_4, 20% NO_2 by weight.
  at 100° C., 20% N_2O_4, 80% NO_2 by weight.
Calcium carbonate $(CaCO_3)$ into calcium oxide (CaO) plus carbon dioxide (CO_2)
  at 600° C., 20 mm. pressure CO_2.
  at 920° C., 760 mm. pressure CO_2.
Mercuric oxide (HgO) into mercury (Hg) plus oxygen (O_2)
  at 400° C., 230 mm. pressure O_2.
  at 500° C., 800 mm. pressure O_2.
Trilead tetroxide (Pb_3O_4) into lead monoxide (PbO) plus oxygen (O_2)
  at 450° C., 5 mm. pressure O_2.
  at 635° C., 760 mm. pressure O_2.
Ammonium chloride (NH_4Cl) into ammonia (NH_3) plus hydrogen chloride (HCl)
  at 350° C., 40% NH_3, 40% HCl, 20% NH_4Cl by volume.
Sulfuric acid (H_2SO_4) into sulfur trioxide (SO_3) plus water (H_2O)
  at 450° C., 0.03% SO_3 by weight.
Sulfur trioxide (SO_3) into sulfur dioxide (SO_2) plus oxygen (O_2)
  at 600° C., 20% SO_2 to 80% SO_3 by volume.
  at 700° C., 50% SO_2 to 50% SO_3 by volume.
Carbon dioxide (CO_2) into carbon monoxide (CO) plus oxygen (O_2)
  at 1230° C., 0.04% CO_2 dissociated.
  at 1730° C., 1.77% CO_2 dissociated.
Water (H_2O) into hydrogen (H_2) plus oxygen (O_2)
  at 1230° C., 0.02% H_2O dissociated.
  at 1730° C., 0.59% H_2O dissociated. (R.K.S.)

ASSOCIATIONS, PLANT. Plants are not distributed in nature in a haphazard fashion, but in habitats in which certain species are present certain others usually occur also. Each such community of plants, composed of more or less the same group of species, is called a plant association. Some plant associations, such for example as the marginal rush or cattail association around a pond, may occupy only localized areas. Other associations, such as some of the grassland or desert shrub associations of western North America may occupy continuous areas totalling hundreds or thousands of square miles. In general, however, plant associations are the smaller units of vegetation occurring within a plant formation (see below) and their distribution is largely controlled by local soil and climatic conditions. Local differences in climate, in turn, are largely a function of topography. Some plant associations, such as a lichen association on a rock cliff, are relatively simple in organization. Others are relatively complex. The oak-hickory association of the eastern United States, for example, is named for the two prominent genera of trees present. Associated with the oaks and hickories, however, are occasional other large trees. In addition there are usually present smaller kinds of trees, species which constitute a shrub story, and herbaceous species which constitute a more or less continuous ground cover.

A larger unit of vegetation than the association is the formation. A *plant formation* usually occupies thousands of square miles and its limits are controlled primarily by climatic conditions. Some of the major plant forma-

tions of North America are the tundra, the boreal forest, the hemlock-hardwood forest, the deciduous forest, the grasslands, the western coastal forest, the western mountain forest, the semi-deserts, and the tropical forests. Within each formation there are usually many different plant associations. Most plant associations are not permanent, but in the phenomenon of **plant succession** one association gradually replaces another. Many successions are in progress in any plant formation. The end results of the successional replacement of one plant association in turn by another is, if the process goes to completion, the establishment of a *climax association*. Such an association is a stable plant community and is not succeeded by any other association; it is the apex of the successional process and, barring changes of climate, will continue to reproduce itself indefinitely. (B.S.M.)

ASSOCIATIVE LAW OF ALGEBRA. Addition and Multiplication.

ASTER. See Mitosis under **Cell Division.**

ASTEROID. The name asteroids (or planetoids) is given to a group of small objects which are members of the **solar system** and whose **orbits** lie, in general, between the orbits of **Mars** and **Jupiter.** The very name asteroid (star-like) describes adequately the appearance of the objects. Only one of them is ever bright enough to be seen with the naked eye and even this one, Vesta, is never a conspicuous object.

The first asteroid discovered, Ceres, was found accidentally by Piazzi on January 1, 1801. His attention was directed to it by noticing the motion of the object through the stars. As the object approached the position of the sun there was danger of its being lost, for the methods of orbit computation were not well developed at that time. The mathematician Gauss went to work on the problem and invented his well-known method for orbit computation, by means of which he was able to predict positions permitting the rediscovery of Ceres after it had passed the sun. Since the orbit was found to lie in the gap between the orbits of Mars and Jupiter, and the object was found to have a mean distance from the sun of 2 8 **astronomical units,** strong support was given by it to **Bode's Law.**

Up to the middle of the 19th century only five more asteroids were discovered, but, with the application of photography to astronomy, the discoveries became more and more frequent until at the present time more than 1300 are under observation. The objects are first detected by noticing the movement of a star-like object through the stars. Photographically, if the camera is arranged to follow the motions of the stars, the star images will appear as dots on the plate while the asteroid image will be trailed out into a short line. The most extensive program of search for asteroids was carried on by Wolf at Heidelburg during the period following 1891. From this time on through the first two decades of the present century Wolf and his assistants are credited with no less than 500 discoveries.

When an asteroid is first discovered it is designated with the year of discovery followed by two letters which indicate the half of the month in which the object was found and the chronological order within that half month. After the orbit of the object has been determined and it proves to be a new asteroid, it is assigned a permanent number, in chronological order of discovery, and the discoverer is privileged to name the object as he may choose. In general, asteroids are given Latinized names with the feminine endings.

Little is known regarding the physical characteristics of the asteroids themselves. The diameters of the four brightest, and presumably the largest, have been measured with large telescopes and found to run from 480 miles for Ceres down to 120 miles for Juno. Estimates of the sizes of the others may be made from the amount of sunlight which they reflect, after making certain assumptions regarding the reflecting power and shape of the objects. The results of the survey indicate that perhaps 150 asteroids have diameters greater than 50 miles, but the majority are between 50 and 20 miles in diameter, with some even smaller than that. Masses and densities can be estimated only from statistical studies but the indication is that the total mass of all of the objects combined cannot be more than 1/600 part of the mass of the earth.

The problem of the determination of the shapes of the asteroids is still one of considerable interest, but for which there is no definite solution. It is well known that the reflected sunlight from many of these objects varies in a periodic manner which can only be adequately explained on the basis of a rotating object. In the case of Eunomia it has been quite definitely proven that the object must be spherical, and that the variation in light is due to different reflecting powers on different parts of the surface. On the other hand, **Eros** has been quite definitely proven to have a "dumb-bell" shape, with the light variations due to rotation of this irregular object.

The orbits of the asteroids have been studied with great zeal ever since the discovery of Ceres. In fact, this group of objects may be considered as a laboratory in which the workers in the field of **celestial mechanics** may test out various theories. Since the orbits lie between the orbits of Mars and Jupiter, and the masses of the asteroids are very small, the planets exert large **perturbations** on the asteroids, while they themselves are virtually unaffected by the asteroid attractions. Many of the methods of computing perturbations were developed as the result of the researches on the orbits of the minor planets. One particularly interesting result is found in the case of the so-called **Trojan Group** of asteroids, which is discussed elsewhere.

There are two theories for the origin of the asteroids. One is that these objects represent a planet that was "spoiled in the making," i.e., never developed into its solid form. The other theory postulates that the asteroids represent the remains of a planet which was formed but disintegrated later on. The latter theory is the older of the two but has gained some considerable strength on the basis of the so-called families of asteroids. Theoretically, it may be proved that, if a planet should be broken up by a series of explosions, the centers of the orbits of the asteroids which are products of any particular explosion, should lie along a line between the sun and Jupiter. In addition to the locations of the centers of the orbits along this line, the mean distances of the products of each explosion from Jupiter would be approximately the same, and also the inclinations of the orbit planes should be similar. As a result of a statistical study of the orbits of the asteroids, five such families of asteroids have been identified and the families each contain from 15 to 44 members. Within the past few years a theory has been gaining weight that the asteroids may be connected in some manner with comets, but as yet the evidence is far from conclusive. (W.K.G.)

ASTEROIDEA. A class of the phylum **Echinodermata.** The starfishes.

The starfishes are distinguished from other echinoderms by the presence of radiating arms or rays, usually five or in multiples of five, which contain part of the internal organs and are usually not sharply separated from the central disk. There are many species but the economic importance of the group is limited. They are sometimes serious pests in oyster beds since they feed largely on shellfish.

The class is divided into three orders: Phanerozonia, Spinulosa, and Forcipulata. (A.W.L.)

Common Starfish. (*N. Y. Zool. Soc.*)

ASTHENIA. Weakness, lack, or loss of strength. (R.S.M.)

ASTHENOSPHERE. A term proposed by Barrell, in 1914, for the zone beneath the relatively rigid **lithosphere.** The asthenosphere is considered to be the level of no strain in which there is maximum plasticity, and in which the **igneous** rock magmas are thought to originate. (R.M.F.)

ASTHMA. A term used to describe a characteristic "wheezing" type of respiration. Wheezing is due to obstruction caused by spasm of the bronchial muscles constricting the bronchi, and by swelling of the **mucous-membrane** lining of the respiratory passages. Asthmatic breathing may be paroxysmal or constant, and it occurs in many conditions. The term bronchial asthma is applied to the paroxysmal form, which appears as a definite clinical syndrome.

Asthma was first described by John Floyer in 1698, but the relation of **hay fever** and asthma to plant pollens and proteins in nature was observed for the first time in 1905 by Dunbar. Following this, the entire picture of the allergic diseases was correlated, and the role of protein sensitivity was demonstrated by means of pollen and protein skin sensitivity tests.

Bronchial asthma is a common disease. The allergic pattern and the asthmatic tendency is strongly familial; some member of the family of an asthmatic has allergic symptoms in at least 40% of cases. The clinical types are classified roughly as those in which the symptom complex is precipitated by extrinsic and intrinsic causes. The extrinsic form is traceable to the same group of substances, pollens and proteins, that usually cause hay fever. The common inhalants are the tree and plant pollens—notably ragweed, animal danders, vegetable powders, and house dust. Foods which are frequent offenders are milk, eggs, wheat and other cereals. Multiple sensitivities to many **antigens** at the same time are common. In adults, inhalants are the usual cause of asthma, and food is rarely so. The reverse is true in children.

Intrinsic asthma, or asthma originating from some cause within the body, is not seasonal and changes of residence or occupation are ineffective in its control. The exciting cause is difficult to determine in most instances. In some cases, however, chronic infection—particularly of the paranasal **sinuses** and the respiratory tract—play a role. Recently, asthma has come to be considered a **psychosomatic disease,** and psychogenic factors are known to precipitate attacks in individuals with an asthmatic tendency.

The symptoms of an acute attack of asthma are wheezy respiration with difficult inspiration and even more difficult long, noisy expiration. In a prolonged and severe attack all of the accessory muscles of respiration are called into action. The attack may last minutes or hours. **Cyanosis** is common. Cough and sticky sputum are frequent. Dry squeaky râles or noises are heard over the lung fields and the breath sounds are distant. As with other allergic diseases, an increase in eosinophils is present in the **blood.** In the interval between attacks, the patient is asymptomatic, and the physical examination normal. Diagnosis is then made on history, and with extrinsic asthma, the offending substances can be identified by means of skin tests.

Treatment of the acute attack consists of the administration of **adrenalin** hypodermically. Stramonium in the form of powders or in cigarettes may alleviate the symptoms. In severe or intractable asthma, additional measures are necessary: aminophylline intravenously, rectal anesthesia (ether in oil or **avertin** in small doses), or the inhalation of 100% **oxygen,** or oxygen and **helium** mixtures may be required.

In the period between attacks, ephedrine combined with a barbiturate (**barbital**) is given as a prophylactic. Adrenalin in oil given intramuscularly has a slow, long-continued action and may help prevent attacks. In cases due to extrinsic allergens, a dust-free, pollen-free atmosphere is effective in decreasing the number of attacks. Similarly, the avoidance of foods to which the patient is known to be sensitive helps to keep the disease under control. In those cases associated with infection, eradication of the infection usually causes an improvement in the asthma.

Complications of asthma occur in long-standing cases. The patients are prone to chronic **bronchitis** and sometimes **bronchiectasis** develops. After years of increased resistance in the pulmonary tree, the right heart hypertrophies under the strain (cor pulmonale); if the strain becomes too great, congestive **heart failure** results. Emphysema and barrel-shaped chest are common. (D.M.H.)

ASTIGMATEA. Chordata, Thaliacea. An order of salpian **tunicates.** (A.W.L.)

ASTIGMATISM. When an optical system fails to bring the rays to a well-defined focus, it is said to be astigmatic. The term is, however, commonly applied to cases in which the fault is due to a lack of symmetry of the optical system about its axis, so that it has different focal lengths in different meridians. This would be true, for example, of a lens, one of whose surfaces is not a true surface of revolution but is slightly ellipsoidal or spoon-shaped. The defect is, unfortunately, quite common in the human **eye,** usually due to radial asymmetry of the **cornea.** When the patient looks at the optometrist's "clock face" or "wheel," the radiating lines along all but one diameter may appear blurred. The remedy is a spectacle lens having an astigmatism of its own at right angles to that of the eye, and to this end use is made of **cylindrical** or **toric** surfaces. (L.D.W.)

ASTROID. Hypocycloid.

ASTROLABE. The astrolabe is an ancient form of portable astronomical instrument invented during the 2nd or 3rd century B.C. probably either by Hipparchus or Appollonius. In its most common form the astrolabe consists of a circular disk which may be suspended by a ring so that it will hang in the plane of a **vertical circle.** A pointer, or **alidade,** is pivoted at the center of the disk and angular graduations are marked about the edge. In addition to the alidade and angular graduations many other astronomical materials such as **constellation** configurations, lists of **planets,** etc., are engraved on the disk. This ornamental engraving is very intricate and beautiful on many of the instruments and makes them interesting museum pieces.

The instrument was undoubtedly intended primarily for the purpose of measuring **altitude** of celestial bodies. For this purpose the ring was suspended by the thumb

of one hand and the other fingers employed to steady the disk as the alidade was moved by the other hand until it pointed directly at the object under observation. The altitude could then be read directly on the disk.

The astrolabe was used by navigators for the determination of **latitude** from the 15th century down to the invention of the **sextant** in the 18th century. It has recently been revived for teaching purposes in elementary classes. (W.K.G.)

ASTROLOGY. Astrology is the ancient art of divining the future of human affairs from observations of the celestial objects. We find records of astrological methods back through the earliest recorded history and during the 14th and 15th centuries astrologers held important positions at many of the courts of Europe. Since observations of the celestial objects form an important part of astrology, the art may be considered as the parent of astronomy although the separation of the art of prophecy from the science of observation certainly took place long before the Christian era.

In the most commonly practised type of astrology a horoscope is drawn up for a person. Such a horoscope consists of a map of the heavens drawn at the instant of birth of the person interested. This map shows the aspects (see **Planetary Motion**) of the planets, the location of the **sun, moon,** and **planets** on the **zodiac** and other correlated phenomena. The signs of the zodiac, or "houses," in which the various objects are located at the time of birth are supposed to indicate all sorts of influence on the future of the person Such words as lunatic, saturnine, ill-starred, etc., indicate the influence of astrology on general culture of past eras. (W.K.G.)

ASTRONOMICAL REFRACTION. In any type of astronomical observation the light from the distant object must pass through the atmosphere of the earth and suffer a change of direction known as **refraction.** The amount of change of direction depends upon two fundamental factors: the relative **refractive index** of the atmosphere and the angle which the ray from the distant object makes with the normal to the surface of the atmosphere. Since the normal to the atmosphere is the direction of the astronomical **zenith** the amount of refraction will depend upon the **altitude** of the object, being greatest when the altitude is least, or when the object is on the **horizon.** The effect of refraction is to make the altitude of an object appear greater than it would be if no atmosphere were present.

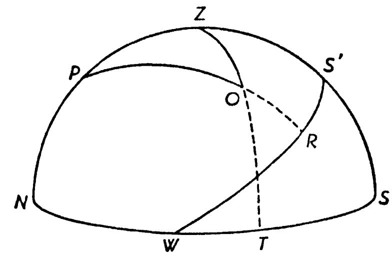
To calculate the amount of astronomical refraction the index of refraction of the atmosphere is needed and, unfortunately, this quantity varies with meteorological conditions. Various theoretical methods for computing the amount of astronomical refraction have been proposed but none of them are very satisfactory for altitudes less than 20°. A fair approximation to the true value may be obtained from the expression

$$R = \frac{983B}{460 + T} \operatorname{cotan} h$$

in which B is the reading of the **barometer** in inches, T is the **temperature** of the air in degrees **Fahrenheit,** h is the apparent altitude of the object, and R is the amount of refraction in seconds of arc. More accurate values may be obtained by using refraction tables such as those published in Bowditch American Practical Navigator. These tables give the amount of refraction in terms of observed altitude, and various meteorological conditions such as temperature and barometric pressure. This refraction must be subtracted from any observed altitude. In case changes due to refraction in other **spherical coordinates** than altitude are desired the **astronomical triangle** must be solved.

Sudden and irregular changes in astronomical refraction are produced by varying meteorological conditions and produce effects of twinkling in the stars. (W.K.G.)

ASTRONOMICAL TRIANGLE. The spherical triangle formed on the **celestial sphere** between the observer's **meridian,** the **hour circle,** and the **vertical circle** through an object, is known as the astronomical triangle. Since practically every problem of **nautical astronomy** deals with the solution of this triangle it will be well to have the definitions of the various parts



Astronomical triangle.

well in mind. In the figure (drawn for an observer in the northern hemisphere) we have:

N, W, and S, the north, west, and south points of the observer's **horizon.**

S', R, W is the celestial **equator.**

Z is the observer's astronomical **zenith.**

P is the north pole of rotation.

O is the object under consideration.

PZO is the astronomical triangle, the various parts of which are defined as follows:

The vertex angles are:

ZPO = the **hour angle** of the object.
PZO = 180°—the astronomical **azimuth** of the object.
ZOP = the parallactic angle.

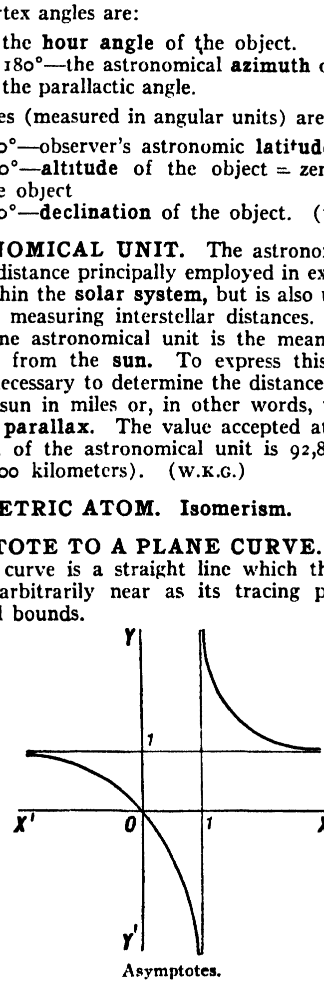
The sides (measured in angular units) are:

PZ = 90°—observer's astronomic **latitude.**
ZO = 90°—**altitude** of the object = zenith distance of the object
PO = 90°—**declination** of the object. (W.K.G.)

ASTRONOMICAL UNIT. The astronomical unit is a unit of distance principally employed in expressing distances within the **solar system,** but is also used to some extent for measuring interstellar distances. Technically defined, one astronomical unit is the mean distance of the **earth** from the **sun.** To express this in miles it becomes necessary to determine the distance of the earth from the sun in miles or, in other words, to determine the **solar parallax.** The value accepted at present for the length of the astronomical unit is 92,897,000 miles (149,504,000 kilometers). (W.K.G.)

ASYMMETRIC ATOM. **Isomerism.**

ASYMPTOTE TO A PLANE CURVE. An asymptote of a curve is a straight line which the curve approaches arbitrarily near as its tracing point recedes beyond all bounds.



Asymptotes.

Thus, in the curve whose equation is $y = \frac{x - 1}{x}$ as shown in the accompanying figure, the lines $x = 1$ and $y = 1$ are asymptotes. (L.L.S.)

ASYMPTOTIC SERIES. A divergent series of the form

$$A_0 + \frac{A_1}{x} + \frac{A_2}{x^2} + \cdots + \frac{A_n}{x^n} + \cdots$$

is said to be an asymptotic representation of a function $f(x)$ if

$$\lim_{x \to \infty} x^n[f(x) - S_n(x)] = 0,$$

for any value of n, where $S_n(x)$ is the sum of the first $n + 1$ terms of the series. (L.L.S.)

"ATABRINE." (Registered in U. S. Patent Office and used in U. S. Dispensary; **"ATEBRIN"** favored by *Chemical Abstracts* and by *British Chemical Abstracts;* **"ATEBRIN"** used in "Merck's Index"; and **"ATEBRINE"** in Thorpe's "Dictionary of Applied Chemistry"). Atabrine is quinacrine hydrochloride, and the full chemical name 3-chloro-7-methoxy-9-(1-methyl-4-diethylaminobutylamino)-acridine dihydrochloride. It is used in the treatment of malaria. The production has been increased since its announcement in 1930, so that in 1942 the quantity was equivalent to the pre-World War II supply of quinine, and this has been increased several times since 1942. Atabrine is yellow in color, and its long continued use results in a harmless yellow pigmentation of all the tissues including the skin. (R.K.S., D.M.H.)

ATACAMITE. This mineral consists partly or entirely of **copper** oxychloride, $CuCl_2Cu(OH)_2$, probably, the exact formula is uncertain. Crystallizes in thin, orthorhombic prisms, may occur massive. Hardness, 3–3.5; specific gravity, 3.76–3.78; luster, adamantine to vitreous; color, green; streak, green; transparent to translucent.

It is a secondary mineral found associated with **malachite** and **cuprite;** originally found at Atacama, Chili, whence its name. Other localities are Bohemia, South Australia, and in the United States in Arizona, Utah and Wyoming. (E.S.C.S.)

ATAVISM. The appearance through **heredity** of characters which have not been developed in the parents of the organism in question. The strict meaning of the word is the reappearance of grandparental characters but it has been used also to designate the reappearance of characters from more remote generations. (A.W.L.)

ATAXIA. Lack of muscular coordination due to disease of the brain, particularly the cerebellum, or spinal cord. **Locomotor ataxia** is the result of degeneration of portions of the spinal cord occurring in the later stages of syphilis. (D.M.H.)

ATAXIC. A term applied by Keyes, in 1901, to all unstratified ore deposits in contradistinction to sedimentary, stratified or **eutaxic** ore deposits. (R.M.F.)

ATELECTASIS. Partial collapse of the **lung,** due most commonly to a mucous plug obstructing one of the bronchial passages. This is thought to be the preliminary stage in the development of most **pneumonias** following surgical operations. (R.S.M.)

ATHLETE'S FOOT. Epidermophytosis.

ATHODYD. Jet Propulsion; Jet Engine.

ATLANTIC SUITE. A term proposed by A. Harker, in 1896, for the chemically and structurally related **igneous** rocks of the Atlantic coast line. Chemically the rocks of this suite are described as **alkaline** and are represented by such types as **granite** and its **magmatic** relatives, as compared with the calc-alkali igneous rocks of the **Pacific Suite.** (R.M.F.)

ATMOSPHERE. The gaseous envelope surrounding any celestial object is known as the atmosphere of that object.

The general characteristics of the atmosphere of any object may be determined theoretically on the basis of the **kinetic theory of gases** and the mass, diameter, and surface temperature of the object. On the basis of this theory and the physical data regarding the various celestial objects, it is determined that the **stars** and all **planets,** except **Mercury,** should have atmospheres, while the **asteroids, moon,** and the satellites of the other planets should be without appreciable gaseous envelopes. The conclusions, drawn from purely theoretical considerations, can be checked by a variety of observations, such as spectroscopic, **albedo, twilight** arch, etc., and the observational results are in close agreement with the theory.

The compositions of the atmospheres of objects external to the earth can be determined from spectroscopic observations. For the stars the problem is relatively simple since the interior radiates a **continuous spectrum,** in most cases, and the cooler gases of the atmosphere produce their characteristic absorption lines. The analysis of planetary spectra is a far more complex problem. In the first place the light that we receive from these objects is sunlight which has penetrated the planetary atmosphere to an undetermined depth and has then been reflected to the earth. Before reaching the observer this reflected light must also pass through the earth's atmosphere. Hence the observed spectrum will be the normal solar spectrum crossed by the multitude of **Fraunhofer lines** due to solar and terrestrial atmospheres, plus lines due to any strange gases that may be present in that portion of the planetary atmosphere through which the sunlight has passed. The presence of any gases in the planetary atmosphere which are also in the solar or terrestrial envelopes will be manifested only by a slight intensification of the absorption lines over those present in the solar spectrum. At certain times the **orbital motion** of the planet has an appreciable component in the direction of the line of sight from the earth. Under these conditions there is a **Doppler shift** of the planetary lines from any corresponding ones in the solar spectrum. The application of high dispersion spectrographs to the study of planetary spectra has employed this Doppler shift and yielded the results given in the articles on the individual planets.

The atmosphere of the earth (see also **Air**) may be considered to extend out to interstellar regions since, in accordance with the kinetic theory, certain molecules may attain velocities greater than the velocity of escape from the earth and also from the solar system. **Auroral** effects have been observed to heights between 500 and 700 miles and we are entitled to say that the earth's atmosphere extends from the earth in sufficient amounts to permit ionization out to these distances. Of this, man has personally explored less than 10 miles; and directly, with instruments, not over 30 miles. What knowledge there is of the remainder is deductively derived from the behavior of radio emanation, auroras, sound waves, etc.

The diagrams presented herewith are self-explanatory. They show much of the interesting electronic and physical nature of our atmosphere, and establish the scale of man's penetration into it. Truly our aeronautical journeys to now have not ventured far from the "shores" of this aerial ocean. The variation of the physical nature of the atmosphere with altitude shows why this has been so.

Much as it must be regretted by men of science that the urge to destroy in warfare advanced in a few short

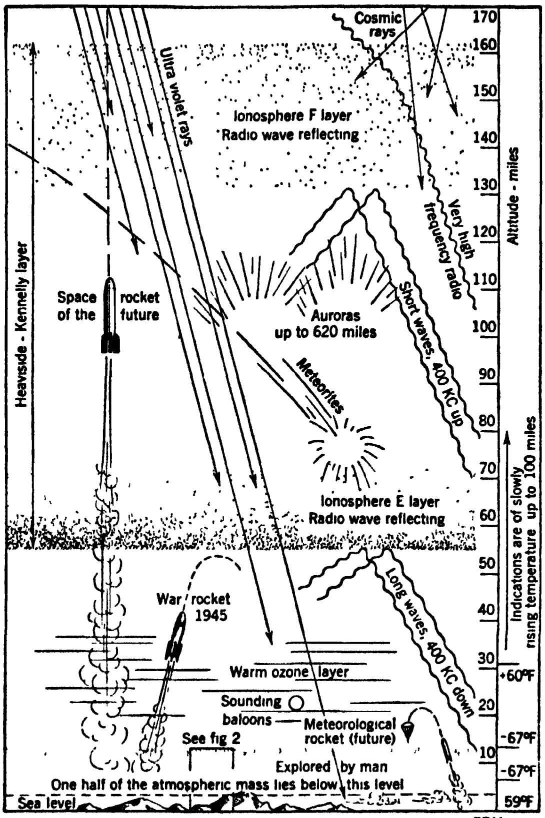


Fig. 1. The lower atmosphere. (Covers the small section indicated in Fig. 2a.)

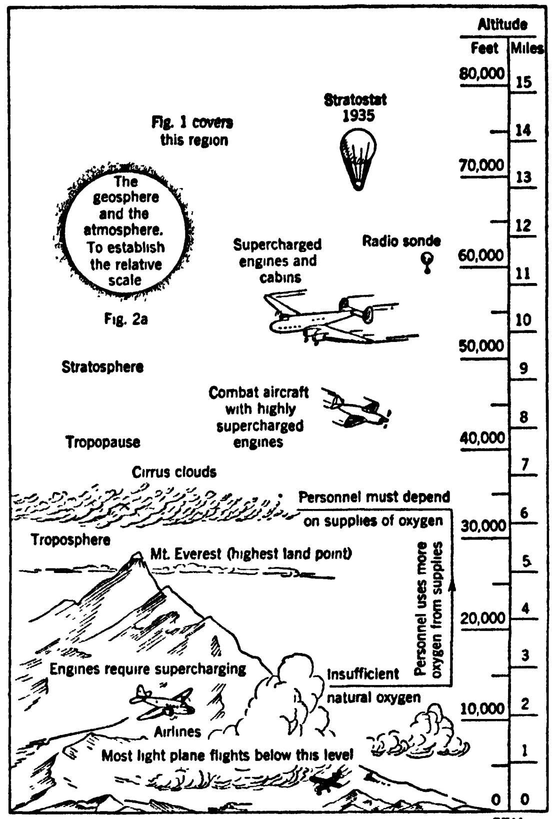

Fig. 2. Detail in Fig. 1.

years the technology of rockets more than decades of peaceful investigation could accomplish, nevertheless they may look to the future with hope that adaptations of the epochal accomplishments of wartime rocketry will provide a means of scientific exploration of our upper atmosphere and of other worlds than ours.

The surveys thus far made indicate that the atmosphere of the earth is composed primarily of nitrogen and oxygen but also contains small amounts of other gases, from 0.01%–3.0% water vapor, dust, smoke, salt crystals, and small amounts of other impurities. Solid particles in the atmosphere account for the blueness of the sky for they scatter part of the sun's spectrum. One-half of the total mass of the air lies below approximately 18,000′ with more than ¾ below 35,000′.

Three general divisions of the atmosphere are recognized. The lower layer is known as the **troposphere,** the middle layer, the **stratosphere,** and the outer layer is known as the **ionosphere.** All storms and practically all cloudiness are restricted to the troposphere. Temperature, in general, decreases from ground or water levels up to the top of the troposphere. There are relatively shallow layers in the troposphere in which the temperature increases, sometimes as much as 50° F., which are known as **inversions.** In general the stratosphere is **isothermal,** but in lower latitudes usually grows continually warmer with increase in altitude to the limit of observational data Very little is known about the thermal structure of the ionosphere from direct measurement, but indirect evidence indicates it is relatively warm. Air density at that level, however, is so small that the temperature would have no meaning in the usual sense. Temperature change with altitude, known as the **lapse rate,** is the principal criterion of differentiation between the troposphere and the stratosphere whose boundary of separation is known as the **tropopause.**

Water vapor in the atmosphere has a varied distribution in the atmosphere being concentrated in greatest quantity in the lower parts of the troposphere. Water vapor enters the atmosphere from several sources, the principal ones being oceans and large lakes plus vegetation-covered land areas in summer. Tropics and subtropics are in general the large-scale source regions of water vapor. From source regions winds carry water vapor elsewhere over the entire globe. Transportation of water vapor is sufficiently localized in character so that tongues and islands of moist and dry air are present everywhere in the troposphere. In the northern hemisphere moist tongues usually flow from south or west, and dry tongues from some northerly direction, except that, particularly during summer, very dry air originating in the subtropical anticyclones often flows from the south and west. In the temperate zone moist tongues normally appear on the west side of anticyclones and on the east side of cyclones, and dry tongues appear on the east side of anticyclones and west side of cyclones.

Pressure-altitude relations in the atmosphere are mathematically precise and can be determined from the hydrostatic equation

$$\frac{\partial p}{\partial h} = -\rho g,$$

and the equation of state for air

$$p = \rho RT,$$

which leads to the relation

$$p = p_0 \left[\frac{T_0 - \lambda h^{g/R\lambda}}{T_0}\right],$$

where p = Pressure,
p_0 = Pressure at height zero,
h = Altitude,
ρ = Density,
g = Acceleration of gravity,
T = Temperature (abs.),
T_0 = Temperature at height zero,
R = Gas constant,
λ = Lapse rate,

when air temperature variation is linear with altitude.

For isothermal air,

$$p = p_0 e^{-gh/RT}.$$

These relations state:

1. Pressure decreases more rapidly with altitude when temperature is low than when temperature is high.

2. Pressure decreases more rapidly with altitude when the lapse rate is large than when it is small.

The Standard Atmosphere has arbitrarily assigned properties and is used for calibration of **altimeters.** Its surface temperature is 15° C., lapse rate is 6.5° C. per km., and surface pressure is 1013.2 millibars (in English units 59° F. and very nearly 3.5° F. per 1000′). It is not very often that the real atmosphere assumes the actual values of the Standard Atmosphere; therefore, altimeters do not often indicate exact altitude. (W.K.G., F.T.M., P.E.K.)

ATOKE. Epitoke.

ATOLL. Coral Reef.

ATOM. The atom may be considered as the smallest particle into which matter can be broken up by chemical means. Though atoms can be further broken up into **electrons, protons, neutrons,** etc., by methods of modern physics, they retain their individuality in chemical reactions and are used as fundamental units in the organization of theory and facts of chemistry. The atomic theory of chemistry is based on the following experimental laws:

1. Law of Conservation of Mass—matter is not created nor destroyed in a chemical reaction.

2. Law of Definite Proportions—compounds contain a definite fixed proportion by weight of the component elements—this proportion being characteristic of the compound.

3. Law of Multiple Proportions—when an element combines with another to form more than one compound, the weights of one element which combine with a fixed weight of the other stand in the ratio of small whole numbers.

On the basis of the above laws Dalton (1808) postulated the atomic theory which states that

1. All matter consists of small indivisible particles called atoms.

2. Atoms of the same element have the same weight, those of different elements different weights so that the atomic weight can be used to characterize an element.

3. Chemical combination is the union of different elements. The combining weight of an element is therefore an integral multiple of the atomic weight.

On the basis of recent discoveries modifications have to be introduced into the original theory of Dalton.

1. Atoms are not indivisible. Some atoms can be made to decompose under the influence of processes involving enormous energies and others decompose spontaneously (radioactivity). Such phenomena do not occur in the ordinary chemical reactions and therefore the usefulness of the Dalton theory in chemistry is not impaired.

2. Atoms of the same element often do not have the same atomic weight but may have several values which differ by several integral units from each other (isotopes). Since different isotopes usually occur in the same ratio, the atomic weight is still characteristic of the element. For further discussion of atomic weights see **Chemical Composition.** (R.K.S.)

ATOMIC BOMB. On August 5, 1945, an atomic bomb, the first of its kind, was dropped on Hiroshima, Japan, with disastrous effects that fully justified the claim that it had more power than 20,000 tons of T.N.T. Atomic bombs involve the disintegration of the nuclei of atoms, not a rearrangement of atoms as in ordinary explosives. Their action is explained under the headings: (1) source of energy; (2) nuclear fission; (3) chain reactions; (4) materials; (5) detonation; and (6) radioactive products. (See **Radioactive Changes; Artificial Disintegration.**)

Source of Energy. Fundamentally the source of energy is found in Einstein's relativity law, according to which energy of amount E has an equivalent mass m given by the law $E = mc^2$, where c is the velocity of light. Experiments in nuclear physics have confirmed the truth of this law, showing that mass associated with matter may disapper on a small scale giving rise to a release of energy of equivalent mass. Einstein's law shows that the loss of 1 unit of matter on the atomic weight scale releases 933 million electron volts (MEV) or approximately 0.001 unit = 1 MEV.

Nuclear Fission. Such a disappearance of matter with release of energy occurs in uranium fission, a phenomenon discovered in 1938 by Hahn and Strassmann in Germany, with Meitner and Frisch playing an important part, and all but discovered by Curie and Savitch in France. This discovery showed that nuclei of uranium atoms (chiefly the U235 isotope as later work showed) by neutron bombardment disintegrate into two atoms of elements of intermediate atomic weights, such stable elements as barium (atomic weight = 137.4), lanthanum (138.9), iodine (126.9), and krypton (83.7) being typical products. In addition, neutrons (probably three) are liberated by the disintegration. As far as the atomic bomb is concerned, fission is of importance for two reasons: (1) a large amount of energy per fission is released; (2) since neutrons are liberated as a result of fission, and neutrons cause fission, there is the possibility of a chain reaction. The large release of energy is due to the fact that the average mass of protons and neutrons in the nuclei of elements of intermediate mass like barium and lanthanum is less than their average mass in the nucleus of the uranium atom. Hence the total mass associated with matter after disintegration by fission is less than the total mass before, with consequent release of 200 MEV per fission. In term of kilowatt-hours this is an extremely small amount of energy but, if all the atoms in 1 ounce of uranium could be disintegrated in this way, the release would be some 250 million kilowatt-hours.

Chain Reaction. To establish a chain reaction there must be enough neutrons produced by fission to allow for the loss of those neutrons which do not cause fission and at the same time leave enough to continue the process. Neutron losses are due to (1) *escape* from the mass of uranium in which they are produced, (2) *capture* by uranium 238 atoms to form U239, and capture by atoms of impurities. The effect of escape is lessened by increasing the size of the unit containing the uranium, because escape is a surface effect, whereas production is a volume effect. Hence the larger the unit, the less the *relative* importance of escape. Loss of neutrons by escape is so important that neither a controlled nor an explosive chain reaction can be produced in a mass of material whose size is below a critical value. Escape is reduced by purifying the uranium and by increasing the concentration of the U235 isotope which undergoes fission many times more readily than U238.

On December 2, 1942, a controlled chain reaction was established in a pile containing purified uranium with isotopes not separated. In this pile use was made

of two facts: (1) very slow or thermal neutrons cause fission in U238 atoms to an extremely slight degree compared with U235 atoms; (2) fast neutrons, the kind liberated by fission, can be slowed down by a *moderator,* that is, by certain substances of low atomic weight like hydrogen (in water, heavy water, or paraffin) and carbon. The pile consisted of a lattice-work of uranium and carbon. In the pile, stray neutrons, which are always about, started the process of fission; the fast liberated neutrons were slowed to thermal speeds by the passage through carbon before reaching an adjacent lump of uranium in which further fission was caused; and so the cycle was continued. Control of the process was possible through the use of strips of cadmium which could be moved in and out of the pile, the element cadmium having the property of absorbing slow neutrons to an exceptionally high degree.

For the successful operation of an atomic bomb two conditions must be fulfilled. (1) A chain reaction must take place so quickly that a large amount of material undergoes fission before the bomb flies apart. (2) There must be control of such a nature that the bomb can be detonated when wanted, but not before. The first condition is fulfilled by surrounding the bomb with an outer layer of heavy material called a *tamper,* which, because of its inertia, prolongs the time after detonation before the bomb actually bursts, and by the use of concentrated explosive material. The tamper has the further advantage that it reduces losses of neutrons by reflecting some of them.

Materials. Uranium 235 and plutonium are suitable materials because in each of these elements fission is brought about by the neutrous liberated by fission. U235 is obtained by separation of the isotopes of uranium, a problem which was one of the major fields of work preparatory to the successful construction of a bomb.

Plutonium is obtained from the U239 formed when atoms of U238 capture slow neutrons. U239 is an unstable isotope disintegrating with a half-period of 23 minutes as follows:

$$^{239}_{92}\text{U} = {}^{239}_{93}\text{neptunium} + \text{beta rays.}$$

Neptunium is also unstable, disintegrating with a half-period of 2.3 days, in the following manner:

$$^{239}_{93}\text{neptunium} = {}^{239}_{94}\text{plutonium} + \text{beta rays.}$$

Although plutonium emits a weak alpha radiation, its half-period is so long that it can be placed in the stable class. Its importance for an atomic bomb lies in the fact, already noted, that it undergoes fission by neutrons. The manufacture of plutonium for bomb material was the primary purpose of large production plants established at Oak Ridge, Tennessee, and at Hanford, Washington. In these plants, involving millions of kilowatts, U235 kept a chain reaction going, and capture of neutrons by the much more abundant U238 isotope provided the plutonium.

Detonation. In a bomb, explosion can be prevented by keeping units of active material below the critical size necessary for a chain reaction. The bomb can be detonated by bringing the fissionable units together quickly. Details of the mechanism used in detonation have not been released, but the report by H. D. Smyth issued by the U. S. War Department suggests that "the obvious method of very rapidly assembling an atomic bomb was to shoot one part as projectile in a gun against a second part as target."

Radioactive Products. The explosion of a bomb, as well as a controlled chain reaction, is accompanied by intense radioactivity. Although the end-products of fission are stable elements like barium, krypton, lanthanum, etc., these final products are the result of successive transformations of intermediate radioactive substances. For example, when lanthanum is an end-product, transformations like the following take place.

$$^{139}_{54}\text{xenon} \rightarrow {}^{139}_{55}\text{caesium} \rightarrow {}^{139}_{56}\text{barium} \rightarrow {}^{139}_{57}\text{lanthanum}$$

Since all isotopes of the elements preceding lanthanum are radioactive, it is evident that fission of any kind is accompanied by radioactivity. When the fisson is as concentrated as it is in a bomb, such activity is intense. (J. K. ROBERTSON, QUEEN'S UNIVERSITY.)

ATOMIC DISINTEGRATION. Radioactivity.

ATOMIC HEAT. Dulong and Petit's Law of Specific Heats.

ATOMIC NUMBER. Chemical Composition.

ATOMIC SPECTRA. An atomic spectrum is the spectrum of radiation emitted by an excited **atom,** due to changes within the atom; in contrast to radiation arising from changes in the condition of a **molecule.** Such spectra are characterized by more or less sharply defined "lines," corresponding to pronounced maxima at certain frequencies or wavelengths, and representing radiation quanta of definite energy.

The lines are not spaced at random. In the spectrum of hydrogen, for example, there is a prominent red line (H_α) and, far from it, another (H_β) in the greenish-blue, then after a shorter wavelength interval a blue-violet line (H_γ), and after a still shorter interval another violet line (H_Δ), etc. One has only to plot the frequencies of these lines as a function of their ordinal number in the sequence, to get a smooth curve which shows that they are spaced in accordance with some law. In 1885, Balmer studied these lines, now called the Balmer series, and arrived at an empirical formula like the following:

$$w = 109678\left[\frac{1}{2^2} - \frac{1}{(n+2)^2}\right].$$

This represents the wave number (number of waves per cm.) for any line, numbered n, in the series. As n increases, the wave number w approaches the "series limit" 27419, toward which the series "converges."

Other series have since been discovered in the hydrogen spectrum, including the Lyman series in the ultraviolet, represented by

$$w = 109678\left[\frac{1}{1^2} - \frac{1}{(n+1)^2}\right],$$

and the Paschen series in the infra-red:

$$w = 109678\left[\frac{1}{3^2} - \frac{1}{(n+3)^2}\right].$$

The coefficient 109678 (cm.$^{-1}$) is known as the **Rydberg constant** for hydrogen. It appears with only slightly differing values as a coefficient in the series formulae for all atomic spectra, a study of which has led to the **combination principle** of Ritz and its interpretation in terms of the **quantum theory;** though in general these formulae are not so simple as in the case of hydrogen. A study of the spectrum of a single element often reveals certain interesting relations between the most prominent series of lines composing it. For example, two series may have the same limit; or the limit of one may equal the limit of the other minus the wave number of the latter's first line, as is seen to be the case with the Paschen and the Balmer series above. Kossel and Sommerfeld noted that if an element is singly ionized, its spectrum resembles that of the element preceding it in atomic number; a fact explained by their having the same number of extra-nuclear electrons.

(See **Hyperfine Structure, Pressure Shift and Broadening,** and **Doppler Effects.**) (L.D.W.)

ATOMIC STRUCTURE. According to Bohr the **atom** is built up of two units—a positively charged

nucleus and a number of negatively charged **electrons.** The nuclear positive charge is equal to the atomic number while the mass is equal to the atomic weight. The electrons have a negative unit charge and a mass 1/1840 of the lightest nucleus. The number of electrons is equal to the charge on the nucleus measured in electron units of electrical charge, thus making the atom as a whole electrically neutral. The atom is essentially hollow with its mass concentrated at the nucleus and a cloud of orbital electrons revolving around it at various distances.

The inert gases occupy a unique position in the table in that the outer shell of electrons contains two electrons in the case of helium and eight in the case of the other inert gases. An outer shell of eight electrons is therefore correlated with chemical inertness. This correlation can be further extended to the other groups of the periodic table where we find in the same group of the periodic table the same arrangement of the electrons in the outer shell of all members of the group. In this way the chemical characteristics of an atom are associated with the number of electrons in the outer shell. (See **Valence; Spectra.**) (R.K.S.)

ATOMIC WEIGHT. **Chemical Composition.**

ATRACHEATA. In some systems of classification of plants, the **Bryophytes** are called Atracheata in distinction to all other plants above the Thallophytes, because they lack a definite **vascular system.** (R.M.W.)

ATRIUM. Literally an entrance chamber, and so applied to various organs. 1. The main part of the cavity of the middle **ear.** 2. The vestibule of the female genital passages. 3. A chamber into which the genital organs open in the flatworms. 4. A cavity formed of folds of the body wall in **Amphioxus** and the **tunicates,** which partially surrounds the **pharynx** and opens to the exterior by an atriopore. 5. The chamber at the end of an air tube in the lungs, with which the ultimate air sacs or alveoli communicate. 6. The chamber of the **heart in vertebrates** which empties into the ventricle. In this sense the term atrium is frequently replaced by auricle, although in strict terminology the auricle refers only to a small appendage of the atrium. (A.W.L.)

ATROPHY. Wasting of or decrease in size of a tissue. This occurs with any interference with the function or use of an organ or part. It may be temporary, as occurs following a fracture when for a period of time the affected limb can be but little used. It also occurs when nerves are injured or affected by disease, or as the result of circulatory accidents such as hemorrhage into the brain interfering with conduction along nerve pathways. If the damage is of permanent character, as results from **infantile paralysis, apoplexy,** or traumatic injury of nerves that cannot be repaired, the atrophy is progressive. With age tissues tend to atrophy, particularly skin, reproductive organs, and occasionally brain. (D.M.H.)

ATROPINE. An **alkaloid** derived principally from the leaves and root of **belladonna.** It is used to allay abnormal contraction and spasm of smooth muscle, especially the smooth muscle of the intestinal tract, and to check secretion of the skin, digestive and respiratory tracts. When given in adequate doses it produces dryness of the mouth and dilation of the pupil of the eye. Except in therapeutic doses, the drug is a poison. (R.S.M.)

ATTAR OF ROSES, OR ROSE OIL. An oil produced from a few kinds of roses, principally from *Rosa damascena.* Bulgaria leads other European countries in production.

In the preparation of the oil, the rose flowers are gathered early in the morning and immediately put into large copper stills. Water is added and then boiled until about 5 quarts have distilled over, carrying with it the rose oil. Fresh roses are added and distilled in the same water. The rose water thus obtained is redistilled separately, yielding the desired rose oil. Recently steam distillation has begun to replace this more primitive method. At best, about 2 tons of roses are necessary to produce one pound of the oil. Quite naturally, rose oil is very expensive, so adulteration by cheaper oils is a common practice. The oil is used principally in **perfumes.** (R.M.W.)

ATTENUATION FACTOR. This is the ratio of the input to the output current of a line or network. The attenuation factor of a series of connected circuits is the product of the individual attenuation factors. (L.R.Q.)

ATTENUATOR. The attenuator, often called a pad, is a network designed to introduce a definite loss in a circuit. It is designed so the **impedance** of the attenuator will match the impedance of the circuit to which it is connected, often being connected between two circuits of different impedance and serving as a matching network as well as an attenuator. It is distinguished from a simple resistance in that the impedance of an attenuator does not change for various values of its attenuation. It is a valuable unit in making many laboratory tests on communications equipment where it is used to adjust the outputs of two pieces of apparatus or for two different conditions so the relative merits may be determined from the attenuator setting. In much communication work it is desirable to transmit power at a higher level than will be used in order to overcome circuit noises, and then to reduce it to the proper value at the receiving end by a pad. It is usually calibrated in **decibels** and thus indicates the attenuation introduced by it. (L.R.Q.)

ATTRIBUTE. **Qualitative Variable.**

ATTRITION. From the Latin *attritio* meaning a grinding or rubbing down, is used in the terminology of geological science to refer to the grinding of particles through the transporting power of wind, running water, or by the movement of glaciers. (E.S.C.S.)

AUDIO AMPLIFIER. **Amplifier.**

AUDIO FREQUENCY. This term refers to the range of frequencies to which the human ear will respond. While the response of the ear varies from person to person, the range is approximately 20–20,000 cycles per second. Below 20 cycles the sound is normally heard not as a note, but as individual pulses. Most persons are unable to hear above 15,000 cycles, but a few people can hear even above 20,000. (L.R.Q.)

AUDITORY ORGANS. Organs sensitive to stimulation by sound waves. True auditory organs occur in **arthropods** and **vertebrates.** In the former they vary considerably but in the latter they are the ears and can be traced through their variations to a common structural foundation.

The simplest **arthropod** auditory organ is known as a chordotonal organ. It consists of a nerve ending with accessory cells connected with the body wall, which is apparently the immediate source of the vibrations to which the organ responds. More elaborate auditory organs are found in **grasshoppers, katydids, mosquitoes,** and related species. In the grasshoppers they are located on the sides of the first abdominal segment, in the katydids in the front tibiae, and in the mosquitoes at the base of the **antennae.** In all forms the **scolophore** is the essential sensory ending; accessory structures vary to a greater degree but usually include a modification of the **cuticula** which serves as a resonating membrane, or tympanum.

The essential auditory portion of the vertebrate ear is the cochlea, a spiral organ of elaborate structure containing terminations of the auditory nerve. This organ is part of the inner ear. In the mammals the outer ear includes the pinna, usually called the ear, and the external auditory canal leading inward to the tympanum or ear drum which vibrates in response to sound waves. Between these two regions lies the cavity of the middle ear, derived from the **pharynx** and connected with it by the **Eustachian tube.** The middle ear is bridged by a series of small bones, the hammer, anvil, and stirrup, which convey the vibrations of the tympanum mechanically to the liquid in the inner ear. These parts are variably developed in vertebrates below the mammals, all of which have simpler ears than described. The ears of **bats** play a unique part in the avoidance of obstacles during flight.

Vibrations ranging in frequency from 30 to 30,000 per sec. are perceived by man as sound. Other animals perceive higher or lower frequencies merging with variable pressures which must be regarded as tactile stimuli. (A.W.L.)

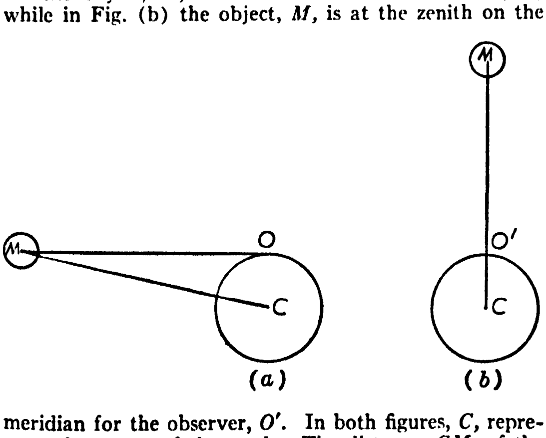
AUGEN-GNEISS. A **gneissoid** rock that contains **lenticular** crystals or mineral aggregates resembling "eyes." Derived from the German *augen,* eyes. (E.S.C.S)

AUGER BIT. Woodworking.

AUGITE. This mineral is a common **monoclinic** variety of **pyroxene** whose name is derived from the Greek word meaning luster, in reference to its shining cleavage faces. Chemically it is a complex metasilicate of **calcium, magnesium, iron** and **aluminum.** Color, dark green to black, may be brown or even white; hardness, 5–6; specific gravity, 2.93–3.49. Augite is important as a primary mineral in the **igneous** rocks and also as secondary mineral. The white augite is called leucaugite from the Greek word meaning white. Chemical analysis reveals this variety as containing little or no iron. Augite is of widespread occurrence. (E.S.C.S.)

AUGMENTATION. This term is used by astronomers to indicate the increase in apparent diameter of the **moon,** or any other object close enough to the earth to be observed as a disk, as the **altitude** of the object increases.

In Fig. (a) we have a representation of conditions for the object, *M*, on the horizon for an observer, *O;* while in Fig. (b) the object, *M,* is at the zenith on the meridian for the observer, *O′*. In both figures, *C,* represents the center of the earth. The distance, *CM,* of the object from the center of the earth is assumed to be a constant. Examination of the figures will show at once that (a), conditions for rising object, gives the maximum distance of the object from the observer, while (b) gives the minimum value of this distance. Since apparent angular diameter of an object increases with decrease of distance, and since we define apparent size as the apparent angular diameter, the object is apparently larger under conditions (b) than in (a). In other words, the object is apparently larger on the **meridian** than when rising. Various attempts have been made, by psychologists and others, to explain the optical illusion that the contrary is the case and that the moon looks larger ("bigger than a house") when rising than when on the meridian.



(a) (b)

For the **sun** and **planets** augmentation is too small to be considered except in the most refined observations of the altitude of a limb. However, in the case of the moon augmentation may amount to as much as 37″. Failure to properly correct for this effect, when a limb of the moon is observed for determination of a **line of position** in **navigation,** might introduce an error as great as 0.3 miles in the position of the ship. (W.K.G.)

AUK. Aves, Charadriiformes. Marine birds (**Aves**) of several species related to the guillemots and puffins. They have a large compressed **beak** with oblique grooves toward the tip. One species, the **razorbill,** *Alca torda,* occurs on both sides of the Atlantic, nesting on rocky ledges. Another, the great auk or **garefowl,** was a flightless species which became extinct through wanton destruction about the middle of the 19th century. (A.W.L.)

AURA. A peculiar sensation which immediately precedes the onset of an epileptic **convulsion.** The aura most frequently arises in the epigastrium and is described as "a gone feeling" by patients. Numbness and tingling of an extremity or the face, palpitation, and dizziness are other forms. Psychic aura consists of feelings of apprehension, fright, horror. (D.M.H.)

AUREOLE. The contact **metamorphic** zone of varying width that often surrounds an **igneous** intrusion. Such areas of contact metamorphism often contain valuable ore deposits, especially when surrounding **batholiths** which have intruded sedimentary formations. (R.M.F.)

AURIC. GOLD.

AURICLE. 1. The outer ear (see **Auditory Organs**). 2. An appendage of the **atrium** of the mammalian **heart.** The term is frequently used as if it were synonymous with atrium. (A.W.L.)

AURICULAR CANAL. 1. The external auditory canal; **ear.** 2. The passage between the **atrium** and ventricle of the **heart.** (A.W.L.)

AURICULARIA. The form of dipleurula **larva** found in the **sea cucumbers.** It is more elongate and compact than the other types and the ciliated band follows an intricately curved path, outlining a conspicuous lobe before the mouth. (A.W.L.)

AURIGA. (The charioteer.) (Map, page 380.) This **constellation** is best known because it contains the bright star **capella** (the she-goat) and her kids. The kids are three fainter stars forming to the naked eye a small triangle and which always serve to distinguish Capella from other bright stars on a clear night. Capella is a bright star, yellowish in appearance, and of the same **spectral type** as our sun. The star, however, is so much larger than our sun that, in spite of its great distance (49 **light years**), it appears as 1st **magnitude,** whereas the sun at the same distance would be 6th magnitude, or barely visible to the naked eye on a clear moonless night. Capella is a spectroscopic **binary** with a period of 104 days. (W.K.G.)

AURIGNACIAN. Paleontology of Man.

AUROCHS. The wild ox of Europe, *Bos primigenius,* ancestor of domestic cattle. It is now extinct but in

some parks of England are half-wild cattle supposed to be descended from this species. (A.W.L.)

AURORA BOREALIS. This well-known phenomenon of the upper **atmosphere** in middle and higher latitudes is now recognized as an electrical discharge in the ionized **air**, exhibiting, as it does, characteristic **spectrum** lines of the rarer atmospheric gases. The aurora appears in a variety of aspects, sometimes as a faintly luminous streak or arch, sometimes as bright streamers like a searchlight beam, sometimes resembling folds of a luminous curtain waved by the wind. Its intensity is greatest in an indefinite region apparently encircling the magnetic pole, toward which the streamers seem to converge. The occurrence of the phenomenon is intermittent, but with distinct evidence of several periodicities. **Sunspot** maxima, with their 11-year period, are always accompanied by maxima in the frequency and brightness of the aurorae. There are also smaller auroral maxima in March and October each year. Aurorae, like sunspots, are practically always attended by disturbances of **terrestrial magnetism.** A corresponding display in the southern hemisphere is called *aurora australis.*

The direct cause of the aurora is not known, but a widely accepted theory attributes it to electrons expelled with great velocity from the **sun**, especially during violent solar disturbances, and entering the upper terrestrial atmosphere, exciting the gases to luminosity like **cathode rays** in a **Crookes** or **Geissler tube.** Such high-speed particles would move in spiral paths along the lines of force of the earth's magnetic field, and hence converge toward the magnetic poles. (L.D.W.)

AURUM. Gold.

AUSCULTATION. This term is applied to the examination of the sounds within the chest, abdomen, heart, or larger blood vessels. It is carried out by listening with a stethoscope, or by applying the ear directly to the surface of the body. (R.S.M.)

AUSTEMPERING. Steel Austenite. Steel.

AUSTRALIAN RAT. Mammalia, Rodentia. Any of several species of the Australian region constituting the genus **Hydromys.** One large aquatic species is known as the beaver-rat. (A.W.L.)

AUSTRALOPITHECUS. Paleontology of Man.

AUTECOLOGY. The division of **ecology** that treats single factors or species in the association of organisms and environment, in contrast with synecology, in which the association of various factors and of species with species is considered. The subject of autecology is closely related with purely physical and chemical studies of environmental factors and with the physiological study of individual animals or plants. (A.W.L.)

AUTHIGENOUS, or AUTHIGENIC. A geologic term proposed by Kalkovsky in 1880, meaning generated on the spot, and referring particularly to the primary and secondary minerals of **igneous** rocks and the cements of **sedimentary** rocks. (R.M.F.)

AUTO STARTER. Starter.

AUTOCHTHONOUS. A geologic term proposed by Gümbel in 1888 for **sedimentary** rocks which have been formed in place. Now generally used to designate bedrock masses that have remained in place in a mountain belt, **allochthonous** masses that have been moved long distances. (R.M.F.)

AUTOCLASTIC. A term proposed by Van Hise in 1894 for crush **breccias** or fault breccias which have been fragmented in place. (R.M.F.)

AUTOCONVECTION LAPSE RATE. Undisturbed air will remain stratified even though the lapse rate exceeds the adiabatic rate of 5.5° F. per 1000′. If, however, the lapse rate becomes sufficiently large, density of the air will increase with altitude and will overturn. This critical lapse rate is 34.17° C. per km. or very nearly 19° F. per 1000′. Dust devils and whirlwinds result from this steep lapse rate which occurs at ground levels, particularly over concrete roads and sand and rock of deserts during the heat of day. (P.E.K.)

AUTOGAMY. A process of nuclear reorganization in **protozoa** in which the **nucleus** divides, each half undergoes a maturation, and the two persisting functional nuclei reunite. In the modified process known as paedogamy the individual forms a cyst within which it divides into two **cells** which reunite after the nuclear transformation is completed. (A.W.L.)

AUTOGENOUS. Self-generated—originating within the body. The term is usually applied to **vaccines** which are made from a patient's own bacteria as opposed to stock vaccines which are made from cultures grown from standard strains. (R.S.M.)

AUTOGYRO. The autogyro is an aircraft on which the lifting **airfoil** surface is not rigidly fixed to the body In consequence of this fact, it has been possible to operate the airfoil with wind velocities greatly exceeding those of the airplane as a whole. As a result, the airfoil surfaces, or vanes, are a great deal smaller in area than those required for a conventional fixed-wing airplane. The autogyro was developed in Spain by Juan de Cievra, and first successfully flown in 1923.

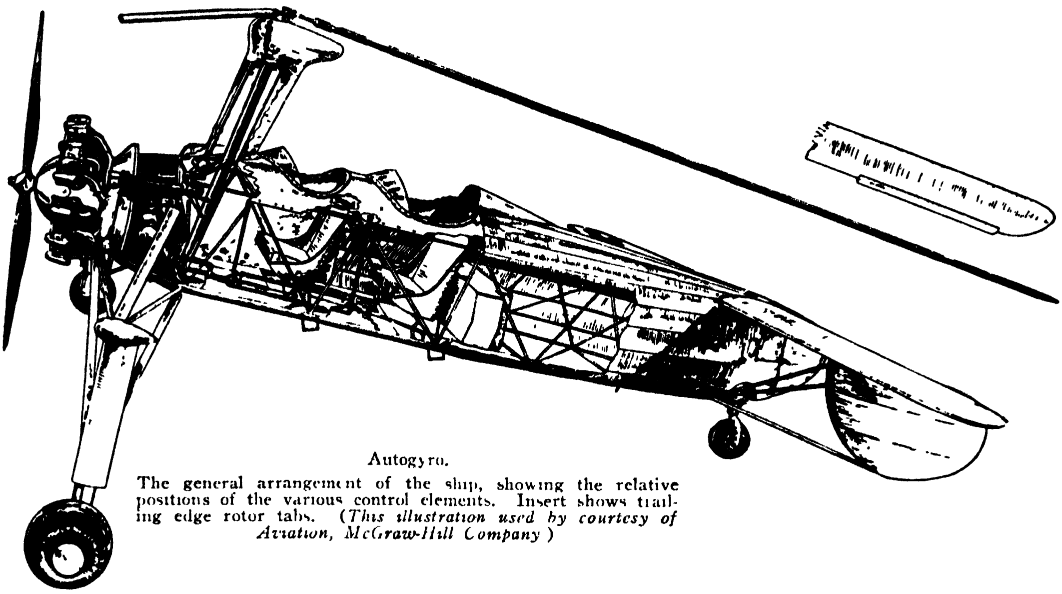
The autogyro consists of a wingless fuselage mounting a pylon which contains a rotating head to which are affixed three or four balanced vanes of airfoil section. The angle of the rotor to the fuselage is controlled by the pilot and this takes the place of the normal control surfaces of the conventional airplane. The vanes rotate at speeds which give an average air velocity over them considerably in excess of the autogyro's air speed, and so the autogyro may be flown at speeds lower than the stalling speed of the airfoil section. This is a great advantage, as it permits the autogyro to land in small fields, with short landing runs, to descend almost vertically, and to approach "hovering" flight.

Although autogyro development has been retarded by recent successes with **helicopter** designs, much of the information gained in autogyro experiments was valuable to the helicopter pioneers. (F.T.M.)

AUTOINTOXICATION. Poisoning by a **toxin** generated within the body, which the body is unable to eliminate. A much abused term covering many undiagnosed diseases of varied and often unknown origin. (R.S.M.)

AUTOMATIC. Usually a machine, mechanism, or machine tool that will go through an indefinite number of operational cycles without manual attendance. (See **Screw Machine, Automatic.**) (H.C.H.)

AUTOMATIC FREQUENCY CONTROL. The automatic frequency control circuits are used in superheterodyne radio **receivers** to keep them tuned to a selected station in spite of random heating effects and other factors affecting the oscillator stability. Because of the method of reception used in these receivers, if the frequency of the local **oscillator** varies it produces a marked effect on the frequency response of the set.



Autogyro.
The general arrangement of the ship, showing the relative positions of the various control elements. Insert shows trailing edge rotor tabs. (*This illustration used by courtesy of Aviation, McGraw-Hill Company*)

Various random effects may cause this frequency to vary and hence the set apparently will get detuned. Automatic frequency control is designed to correct for these random effects and keep the local oscillator frequency at such a value that the intermediate frequency is kept constant. In this circuit the output of the intermediate frequency amplifier is fed into a **discriminator** as well as into the regular **detector**. The output of the discriminator is used to bias a **reactance tube** which is serving as part of the tuning circuit of the local oscillator. By proper adjustment of the circuit values the variation of the reactance tube can be made to keep the intermediate frequency constant within narrow limits and thus keep the receiver tuned. A similar automatic frequency control circuit is used to control the **carrier frequency** of some systems of frequency **modulation**. Here some of the output signal is fed into the discriminator which is adjusted so only the average or carrier frequency variation will produce a bias for the reactance tube. (L.R.Q.)

AUTOMATIC PILOT. This is a mechanism, the purpose of which is to control the movement of an airplane about its longitudinal, lateral, and vertical axes. The mechanism produces forces on the control system (see **Controls, Airplane Flight**) which act in parallel with those of the human pilot. The latter may at will overpower the automatic pilot, render it inoperative, or relinquish piloting of the airplane to it The automatic pilot is primarily a mechanism designed to maintain the airplane in a constant heading (which may be set by the pilot) and in either level flight or constant climb or glide attitude. It does not perform flight maneuvers of an acrobatic character.

The automatic pilot has been brought to a high state of development, particularly in the United States. As might be expected from the complex nature of the action it performs, the mechanism is extensive and complicated. This, together with the demand for utmost reliability, raises design and manufacturing problems, the surmounting of which is to the credit of American scientific and mechanical talent. The mechanism is based on the principle of constancy of position of a universal mounted gyroscope and its action involves both pneumatics for gyroscope drive and primary signal, and hydraulics for the necessary large actuating forces. It is therefore seen to be a mechanical instrument.

A version of the automatic pilot made in large quantities in the United States consists essentially of two gyroscopic control units (one for pitch and bank control, the other for directional control), three servo units consisting of long stroke pistons in oil cylinders, one each for aileron, rudder, and elevator control, and numerous accessories for the supply of oil and air. The gyroscopes and their drives are mounted on the pilot's instrument panel where they provide a visual indication of the attitude and heading of the plane. The other elements are distributed where most convenient or practical, with connections between them being principally through pneumatic or hydraulic tubing.

A gyroscope is a spinning wheel which is universally mounted. A fundamental property is that the spinning axis tends to remain fixed in space, as is illustrated in Fig. 1. This property is called "rigidity," and is the

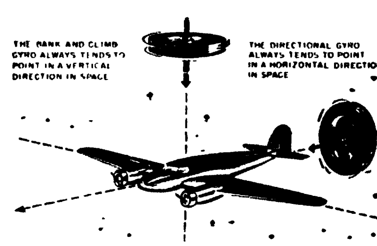


Fig. 1. The gyro in space (*Sperry Gyroscope Co.*)

basic principle in the operation of all automatic pilots. Any movement of the airplane about one of its three axes will move the case of the gyroscope but will not affect the position of its spinning axis. This relative movement between gyro and case is utilized to produce unbalanced air pressures on a diaphragm. The resultant diaphragm movement operates an oil relay valve which admits oil under pressure against the piston of a servo-motor, causing it to execute a stroke and move the proper control surface to a correcting position. Typical connections of the servo units into the flight control system are shown in Fig. 2, which, however, omits hydraulic lines for the purpose of clarity. In order to remove the applied control as the airplane is returning to its normal attitude, so that the control surface will be in its neutral position when the disturbance has been corrected, there must be a follow-up system which returns the mechanism to neutral position when the airplane has returned to the desired attitude.

In Fig. 2 the follow-up system is seen to consist of cables which follow the control cable movement and transmit it back to the gyro control unit.

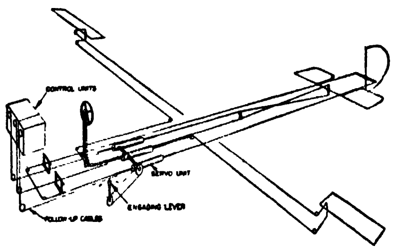

Fig. 2. Diagram of the incorporation of an automatic pilot in a flight control system. (*Sperry Gyroscope Co.*)

Automatic pilots have proven valuable for the relief of pilot fatigue on long flights, especially through overcast. Their use allows the pilot fuller opportunity to consider the operation of other components of his airplane and more freedom for executive and navigational duties.

In the latest versions of the automatic pilot the gyroscopic units have remained substantially the same but electronic means have been substituted for hydraulic means in picking up the indications of the gyroscope and converting its signals into actuation of the controls. Also, drive is electric rather than pneumatic. (F.T.M.)

AUTOMATIC VOLUME CONTROL. An automatic volume control circuit is incorporated in a **radio** receiver to maintain the amplitude of the signal applied to the **detector** as nearly constant as possible and thus correct for variations in signal strength caused by **fading.** When a modulated radio-frequency wave is detected the output contains a d-c component which has a magnitude proportional to the amplitude of the **carrier** impressed on the detector. Other components (af and rf) are filtered out and this d-c voltage is applied as **bias** to the **variable mu** radio frequency amplifiers. Fig. 1 illustrates the essential components of such a system, the resistance and capacitance units

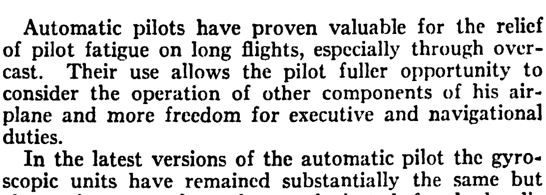

Fig. 1. Simple automatic volume control circuit

indicated as L serving to separate the various components of the detector output and route them to the proper parts of the complete receiver. The d.c. for the avc is fed, as indicated, to the grid of the rf tubes, usually all being so biased although only one is shown. Thus a high value of applied signal gives a high value of d-c output which is applied to the variable mu tube, making its grid more negative and thus decreasing its gain and reducing the signal applied to the detector. A low value of carrier gives a lower value of d.c. which means less negative bias on the rf tube, hence more gain and increased signal to the detector. (L.R.Q.)

AUTOMOBILE. Motor Vehicle.

AUTOMOBILE ENGINE. Otto Cycle Engine.

AUTONARCOSIS. Literally self-numbing. **Anaesthesia** resulting from accumulated products of the animal affected. (A.W.L.)

AUTONOMIC NERVOUS SYSTEM. (Involuntary nervous system, vegetative nervous system.) A functional division of the nervous system consisting of ganglia, nerves, and plexuses through which visceral organs, heart, blood vessels, glands, and smooth muscle receive their innervation. It is widely distributed over the body, especially in the head and neck, and in the thoracic and abdominal cavities. The autonomic system is not under voluntary control and the processes in which it is concerned are beneath consciousness for the most part. It is influenced to a great degree by the **endocrine glands,** particularly the adrenal and its hormone, epinephrine.

In general the autonomic nervous system may be divided into two groups both of which may send nerves to the same organs but act antagonistically, producing opposite results. One is known as the parasympathetic, which arises from the mid-brain, hind-brain, and sacral region of the cord and is stimulated by the drug **pilocarpine** and inhibited by **atropine.** The other is known as the sympathetic, which arises from the thoracic and lumbar regions of the spinal cord and is stimulated by epinephrine (see **Adrenalin**).

Under normal conditions there is a balance between the two systems allowing for perfect function of a bodily organ. For instance, the heart is slowed by the parasympathetic system and accelerated by the sympathetic. Movement of the stomach is increased by the parasympathetic and is inhibited by the sympathetic. The pupil of the eye is contracted by the parasympathetic and dilated by sympathetic stimuli. (D.M.H.)

AUTO-OXIDATION. Oxidation.

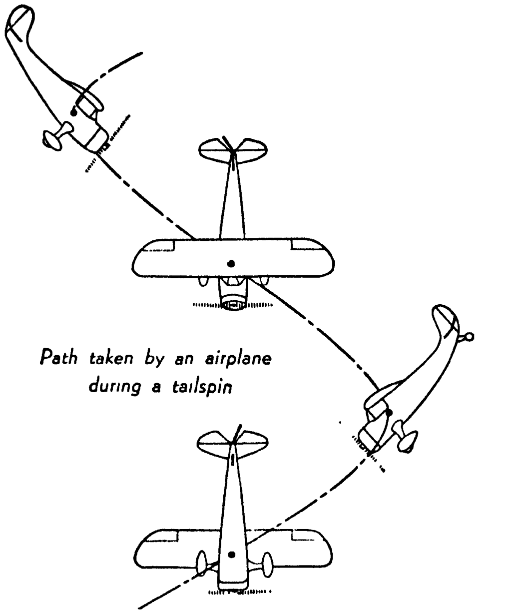
AUTOPSY. Necropsy.

AUTO-ROTATION. Auto-rotation, more commonly known as the tailspin, is a property of the motion of an **airplane** under a special set of circumstances. The attitude of an airplane, when spinning, is with the longitudinal axis rather steeply inclined to the horizontal; indeed, some airplanes spin almost "nose down." Furthermore, the airplane has a rolling motion which makes a vertical **helix** of the flight path during spinning. The peculiar significance of auto-rotation is that it is uncontrolled flight, and that recovery from it is not to be accomplished without the loss of 200–600′ of altitude; consequently, when spinning begins within this height above the ground level, a crash is very likely to ensue.

The action of auto-rotation is briefly described as follows. It is essentially a stalled maneuver, and can not be intentionally or unintentionally gotten into when the speed of the airplane exceeds that of its stalling speed. But when the airplane is flying at a speed equal to that at which it will **stall,** and a slight gust or change of angle of attack causes either a slight **roll** or a **yaw,** unless the pilot immediately and forcibly corrects the same to bring the ship again on the level keel with a slight increase of speed, the yaw will induce a roll (or the roll a yaw). It is the property of the conventional type of airplane that a roll produced by a yaw increases that yaw, and so results in an increasing roll. At the stalling speed **ailerons** become inoperative, and the pilot has no control which will permit him to correct this roll, so the airplane goes into a tight spiral dive which is almost immediately followed by the auto-rotative condition, in which the wings are operating at an **angle of attack** above that of the stall. Although the "twisted" wing (one whose angle of attack is not the same at all stations of the semi-span) possesses some undesirable aerodynamic features, it has this virtue: if the center section has the greater incidence, it will burble before the tips, with sufficient loss of lift to cause the airplane to nose down to a greater speed and smaller angle of attack. The tips, remaining unstalled, tend to oppose the rolling tendency and any roll that develops may be counteracted by the ailerons

which remain effective while the tip is unstalled. An opposite character of twist accentuates auto-rotation and may produce undesirable and dangerous spinning qualities in the airplane.

Recovery from auto-rotation is ordinarily accomplished by operation of the elevators and rudders, so as to decrease the angle of attack of the wings, allowing



Path taken by an airplane during a tailspin

them to recover their lifting power, and giving to the tail surfaces the required maneuverable power to cause the pilot to be able to stop the rotation, and bring the airplane to an even keel. It has been possible to build airplanes which either will not spin, or which can be prevented from spinning at any time by the use of controls, especially of ailerons which are operative at the stall. (F.T.M.)

AUTOTOMY. Self-mutilation. Through the presence of a special modification near the base of the limb, some crustaceans and insects are able to drop off appendages by which they are seized. The autotomy of the arms of starfish and of the tail of lizards are other common examples. Autotomy is followed by regeneration. (A.W.L.)

AUTOZOOID. Members of **polyp** colonies whose function is to feed the colony. (A.W.L.)

AUTUNITE or CALCO-URANITE. This mineral is a hydrous **phosphate** of **calcium** and **uranium**, crystallizing in the **orthorhombic system**, usually in thin tabular crystals. Good basal cleavage; hardness, 2–2.5; specific gravity, 3.1; luster, subadamantine to pearly on the base; color, lemon yellow; streak, yellow; transparent to translucent; strongly fluorescent.

Originally from near Autun in France, whence the name, it is a secondary mineral associated commonly with **uraninite.** In the United States occurs sparsely in the pegmatites of Connecticut, New Hampshire and North Carolina. (E.S.C.S.)

AUXILIARY PROJECTION. Orthographic Projection.

AUXINS. The name given to a group of growth-regulating substances occurring in plants which have profound effects on the elongation of plant cells and other important growth phenomena. Three such compounds have actually been isolated from plant tissues: auxin *a* ($C_{18}H_{32}O_5$), auxin *b* ($C_{18}H_{30}O_4$), and heteroauxin ($C_{10}H_9O_2N$). In addition to these compounds known to be present in plants a number of synthetic compounds are known to exert similar or identical effects on plants. These are also often referred to as auxins and for convenience will be discussed under this heading in this treatment. The auxins exert their effects on the growth of plants when present in exceedingly minute quantities. Their effects are typical of **hormones** and the auxins are one of the important groups of plant hormones.

The first effect of the auxins to be discovered, and probably their most fundamental influence on plant growth, is that on the elongation of cells. During the growth process all plant cells go through the successive stages of cell division, cell elongation (or enlargement), and cell maturation. Auxins are absolutely essential for the occurrence of the elongation stage of growth. In their absence elongation or enlargement of cells ceases. In their presence elongation occurs if all other factors are also favorable for growth and, within limits, the elongation is proportional to the auxin concentration. Relatively high concentrations of auxin, however, inhibit cell elongation, the optimum concentration for cell elongation being different in different tissues. Concentrations which favor elongation of cells in stems, for example, may completely inhibit the elongation of cells in roots.

Another effect of the auxins is on root formation. More roots form, and more quickly, on the cuttings of many kinds of plants if they are first immersed in a dilute solution of one of the auxins before placing them in the rooting medium than if they are not so treated. Indolebutyric acid and alphanaphthalene acetic acid, both synthetic auxins, are especially effective in inducing root formation. The hormone may be applied to the cuttings in a solution, in a paste, as a vapor, or in a powder. Immersion for about 24 hours in a solution containing 5 to 20 mg. of either of these two substances per 100 cc. of water is effective in favoring root formation on many kinds of cuttings.

Fruit development on plants normally occurs only after **pollination** and subsequent **fertilization** have taken place. If pollination is prevented and any one of several of the auxins is introduced into the pistil by a suitable technique, development of a **parthenocarpic** fruit will result. Such fruits are seedless. During the winter season of low pollen viability treatment of greenhouse tomato flowers with indolebutyric acid results in a larger set of fruit.

The **abscission** of leaves, fruits and other plant parts from the stems can also be influenced by auxins. Artificially introducing auxin into the petioles of leaves at a time when they would normally abscise within a short period often appreciably delays the time required for the leaves to fall. Fruit fall can also be delayed by spraying with a solution of alphanaphthalene acetic acid shortly before harvest time. This practice is now widely followed in apple orchards. Application of the hormone spray delays abscission of the fruits and lengthens the period during which the apples can be picked from the tree.

Auxins also play an important part in the phenomena of phototropism and geotropism (see **Movement in Plants**). (B.S.M.)

AUXOSPORE. An auxospore is a special type of **spore** which occurs in **diatoms** and which seems to be a means of rejuvenating the cells. Rejuvenescence is necessary, since in the normal process of cell division one of the two daughter cells is always smaller than the parent cell. Consequently very small cells are ultimately formed. In some species of diatoms, auxospore formation is preceded by the escape of the protoplast from the walls of the cell. The free **protoplast** then enlarges and secretes about itself a wall. In time new valves more or less like those of the original

diatom are formed. In other species of diatoms, auxospore formation is preceded by the union of the protoplasts of two similar diatom cells, the process being therefore sexual. (R.M.W.)

AVAHI. Mammalia, Primates. The woolly **lemur**, *Avahis laniger*, of Madagascar. (A.W.L.)

AVAILABLE ENERGY. Energy which can be converted into mechanical work by means at human disposal. While incalculable quantities of **energy** exist all about us, only an insignificant fraction of it is in such form that human invention has been able to utilize it for the performance of work. For example, water stored behind a dam has a supply of potential energy, some portion of which can be made to drive our machinery as it descends to the sea. But when it reaches the ocean level, though it still possesses energy, what is left is not available for use, because it cannot flow to a lower level as it might if the ocean basin were empty. Again, there is an abundance of the kinetic energy called **heat**, since the air, the ground, and bodies all about us are at temperatures far above **absolute zero**. But the second law of **thermodynamics** requires that to utilize any of this supply we must have a region colder than these bodies, into which heat would naturally flow from them. And even when such a region is at hand, as in the case of the relatively cool atmosphere surrounding an engine boiler, our best engines manage to capture only a small percentage of the thermal energy on its way from the hotter to the colder body.

A most disconcerting aspect of the subject is the fact that even if energy is available, it is not content to remain so until we are ready to use it, but takes every opportunity to escape and become unavailable. This is equivalent to the **least energy principle**, which may be expressed by saying that a system cannot be in stable **equilibrium** until it has got rid of all the available energy that it can. Any process in which available energy thus becomes unavailable is said to involve "degradation" or "dissipation" of energy. (See **Entropy.**)

Cosmic physicists long have recognized that the continued operation of this dissipative principle can result in only one ultimate condition, namely, that the entire universe will become in the end an absolutely cold, motionless lump of matter (if, indeed, the "proper energy" composing matter itself does not succumb, in which case there would be no matter). This fate, significantly expressed by the German term *Wärmetod* ("heat death") must surely overtake the cosmos unless, as some think, compensating influences are operating somewhere to prevent it. (L.D.W.)

AVENA. Oats.

AVERAGE. An average is a single value found by some mathematical process from a distribution of **variates.** It is in some way typical of the whole distribution.

Instances of simple averages are the **measures** of **central tendency.** More complex instances of averages are the **moments** of a distribution. (L.A.A.)

AVERAGE DEVIATION. Average deviation or mean deviation, M.D., is a measure of **absolute variability** in which the **deviations** are generally referred to the **mean.** It is defined by the formula

$$\text{M.D.} = \frac{\Sigma |x_i - \bar{X}|}{N} = \frac{|x_1 - \bar{X}| + |x_2 - \bar{X}| + \cdots + |x_N - \bar{X}|}{N}$$

in a **serial distribution** where x_i are the variates, $\bar{X}$ the mean, and $|x_i - \bar{X}|$ is the absolute **deviation** of x_i from $\bar{X}$, and by

$$\text{M.D.} = \frac{\Sigma f_i |x - \bar{X}|}{\Sigma f_x} = \frac{f_1 |x_1 - \bar{X}| + f_2 |x_2 - \bar{X}| + \cdots + f_N |x_N - \bar{X}|}{f_1 + f_2 + \cdots + f_N}$$

in a **frequency distribution** where f_i is the frequency in the class whose class mark is x_i. It shows on the average how far the variates are from the mean. Its uses are very restricted. The **standard deviation** is by far the preferred measure of dispersion. In the **normal probability function** M.D. $= \sqrt{\frac{2}{\pi}}\ \sigma_x = .7979\sigma_x$, $\sigma_x =$ the standard deviation. The average deviation is least when the deviations are referred to the median. (L.A.A.)

AVERAGE OUTGOING QUALITY LEVEL. The average outgoing quality level is the average per cent defective in the product after inspection, which shall not be exceeded no matter what may be the level of per cent defective in the product submitted to the inspector. (L.A.A.)

AVERTIN. **Anaesthesia.**

AVES. The birds. A class of the phylum **Chordata** which is marked chiefly by a high degree of specialization for flight. The great beauty of many species of birds, their songs, their interesting nesting habits, and the fact that few regions are so inhospitable as to be without birds, have led to wide interest in the group.

Birds are distinguished by several structural characteristics, although the first alone is sufficient for their recognition. 1. The skin is clothed with feathers. 2. The jaws are ensheathed in a horny **beak** and bear no teeth. 3. The pectoral appendages are usually modified for flight, forming **wings,** although they are rudimentary in some species and aid in swimming in some. 4. The **skeleton** is made rigid by the fusion of bones. 5. The **heart** is 4-chambered. 6. Birds are warmblooded (Homoiothermal).

As is true of all extensive groups, the birds are very diverse in habits. They are both herbivorous and carnivorous and are further specialized as seed-eating, fruit-eating, insect-eating, fish-eating, and other types. They are also specialized as swimming, wading, walking, running and diving forms, in addition to their usual ability in the air, and in a few cases they burrow effectively. Their nesting habits also vary remarkably and the construction of the nest is in many cases a source of wonder.

The seasonal **migrations** of birds are almost unique. No other group of animals is so generally characterized by this tendency. The subject has been widely studied and has aroused much speculation without being clearly understood. It is obviously correlated with seasonal variation in the food supply and with climatic conditions, and is made possible by high specialization for flight, but exact knowledge of cause and effect in migration is lacking.

The economic importance of birds is great, and is chiefly to their credit. Insect-eating species destroy countless pests and seed-eating species aid in checking the spread of many weeds, although they may also rob the farmer of a small part of his crops. Scavengers like the turkey **vultures** are useful, although the degree of their usefulness is difficult to estimate. On the other hand a few **hawks** and **owls**—and only a few—do some harm by destroying useful birds and the **crow** is given a very bad reputation by conservation experts as a robber of the nests of other birds. It is scarcely necessary to mention the value of birds as food and game. The domestic species, **chickens, ducks, turkeys, geese,** are too well known as food, and their eggs are too common a culinary material to be readily overlooked.

Probably because specialization for flight overshadows other adaptations, the classification of birds has been

subject to some difficulty. The birds are divided into two subclasses by some writers, the Ratitae including flightless birds whose **sternum** is without the deep keel to which the powerful flight muscles are attached, and the Carinatae with a keeled sternum. These divisions are not, however, clean cut, hence the classification in twenty-five orders now in common use is given below.

Order Struthinioformes. **Ostriches.**
Order Rheiformes. **Rheas.**
Order Casuariiformes. The **emu** and **cassowary.**
Order Crypturiformes. The **tinamous.**
Order Apterygiformes. **Kiwis.**
Order Sphenisciformes. **Penguins.**
Order Gaviiformes. The **loons.**
Order Colymbiformes. **Grebes.**
Order Procellariiformes. **Albatrosses** and **petrels.**
Order Pelecaniformes. **Pelicans, gannets, darters, cormorants,** etc.
Order Ciconiiformes. **Herons, spoonbills, flamingos, storks, bitterns,** etc.
Order Anseriformes. **Swans, geese, ducks,** etc.
Order Falconiformes. **Eagles, falcons, hawks, vultures,** etc.
Order Galliformes. **Turkeys, pheasants,** etc.
Order Gruiformes. **Cranes, rails, gallinules, coots.**
Order Charadriiformes. **Gulls, plovers, curlews, auks,** etc.
Order Columbiformes. **Pigeons.**
Order Psittaciformes. **Parrots** and related species.
Order Cuculiformes. **Cuckoos,** etc.
Order Strigiformes. The **owls.**
Order Caprimulgiformes. The **goatsuckers,** including the **whip-poor-will** and **nighthawk.**
Order Micropodiformes. **Swifts** and **hummingbirds.**
Order Coraciiformes **Kingfishers, hornbills,** etc.
Order Piciformes. **Woodpeckers, toucans,** etc.
Order Passeriformes. An immense order including over half the known species of birds, among them the more familiar land species. The **thrushes, sparrows, warblers, swallows, flycatchers, larks, wrens, titmice** and many others. (A.W.L.)

AVIARY. A building or other enclosure for the maintenance of birds in captivity. (A.W.L.)

AVICULARIUM. A modified individual resembling the head of a bird, occurring in **bryozoan** colonies. (A.W.L.)

AVIGATION. The term avigation was introduced some years ago to describe the general subject of air **navigation.** The general methods of sea and air navigation are so closely interwoven at the present time that the term avigation has been virtually abandoned. In this encyclopedia the various topics of air and sea navigation are discussed together under the specific titles used by navigators in general. (W.K.G.)

AVITAMINOSIS. A state of malnutrition resulting from deficiency of **vitamins** in the diet, or inability to assimilate them through the gastrointestinal tract. Such deficiency of the different vitamins causes various diseases, such as **beri-beri, scurvy,** etc. Extreme avitaminosis, untreated, may cause death. (See **Vitamins.**) (D.M.H.)

AVOCADO or ALLIGATOR PEAR. *Persea americana.* Lauraceae. This tree, a native of the lowlands of tropical America, has been extensively cultivated in tropical and sub-tropical regions. It has been introduced into Florida and California, where, due to its non-hardy character, it is often injured by frosts. It is an attractive tree with large oval to ellipical leaves and small yellowish flowers. The large green to brownish fruit varies in shape from nearly spherical to pear-shaped. It is extremely nutritious and rich in oil, and is becoming increasingly popular in American markets. The thick yellowish flesh of the fruit has only a faint flavor, and therefore is usually served with salt, vinegar, or oil. (R.M.W.)

AVOCET. Aves, Charadriiformes. *Recurvirostra.* Wading birds (**Aves**) of several species found in the Old and New World. The **beak** is curved upward at the tip and the feet are fully webbed. (A.W.L.)

AVOGADRO'S LAW. The well-recognized principle known by this name was originally a hypothesis suggested by the Italian physicist Avogadro in 1811, to explain the puzzling rule of proportional volumes observed in chemical reactions of gases and vapors. It states simply that equal volumes of all gases and vapors at the same temperature and pressure contain the same number of molecules. Though this assumption accords with the facts and aids the kinetic theory of gases, just why it should be true is by no means self-evident; unless one starts with the much more recent Maxwell-Boltzmann law of **equipartition of energy,** which also requires proof. That Avogadro's law is true cannot be said to have been positively established until the experiments of J. J. Thomson, Millikan, Rutherford, and others determined the value of the **electron** as an electric charge and thereby made it possible to count the number of atoms of different elements in a gram. It is now known that 1 cc. of any gas at normal temperature and pressure consists of close to 2.687×10^{19} molecules (Loschmidt's number), and that the number of molecules in a mole of gas is 6.023×10^{23} (Avogadro's number). (See **Chemical Composition.**) (L.D.W.)

AWN. An awn is a slender projection found on the **lemmas** of many grasses. In some forms the awn arises from the tip of the lemma; in others from a point near the base. Commonly they are barbed, and not infrequently spirally twisted. They are particularly well developed in **barley.** (R.M.W.)

AXES OF AN AIRCRAFT. Three fixed lines of reference, usually centroidal and mutually perpendicular. The horizontal axis in the plane of symmetry, usually parallel to the axis of the propeller, is called the longitudinal axis; the axis perpendicular to this in the plane of symmetry is called the normal axis; and the third axis perpendicular to the other two is called the lateral axis. (See **Airplane.**) (F.T.M.)

AXIAL GRADIENT. An axis of organization characterized by progressive metabolic (see **Metabolism**) dominance. As formulated by C. M. Child the bilaterally symmetrical body is organized on a primary axis from head to tail, a secondary axis from dorsal to ventral and paired tertiary axes from the median plane to the lateral extremities. In any axis, beginning at the point mentioned first, and in the entire body proceeding from axis to axis in the order named, metabolic dominance is evident in functions and in development over lower levels or subordinate axes. (A.W.L.)

AXIAL LOAD. Load.

AXIAL ORGAN. An **organ** of peculiar structure and unknown function found near the axis of the body in all **echinoderms** except the **sea cucumbers.** (A.W.L.)

AXIAL SINUS. A portion of the body cavity in **echinoderms** into which the pores of the **madreporite** open. (A.W.L.)

AXIAL STRESS. Stress.

AXIL. The angle between the upper side of a **leaf** and the **stem** to which the leaf is attached is called the axil of the leaf. (R.M.W.)

AXILLA. The armpit. (D.M.H.)

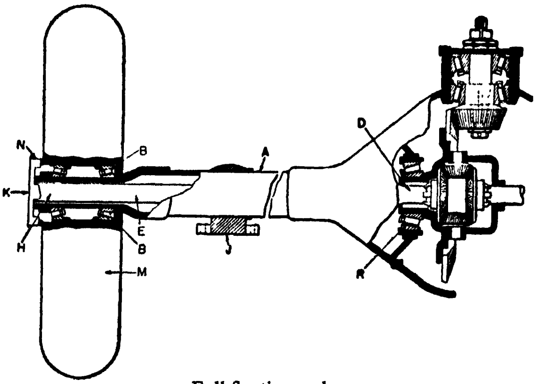
AXINITE. This mineral is an **aluminum-boron-calcium silicate with iron and manganese.**

Crystallizes in the **triclinic system** yielding broad sharp edged forms, which has led to its name, derived from the Greek word meaning axe.

Axinite breaks with a **conchoidal** fracture; hardness, 6.5–7; specific gravity, 3.27–2.29; luster, vitreous; colors, brown, blue, yellow and gray. Transparent to translucent. Occurs in granites or more basic rocks along contacts and in cavities in Saxony, Switzerland, France, England, Tasmania and Japan. In the United States, in New Jersey, Pennsylvania, and California. (E.S.C.S.)

AXIS OF INSTANTANEOUS ROTATION. Dynamics of Rotation.

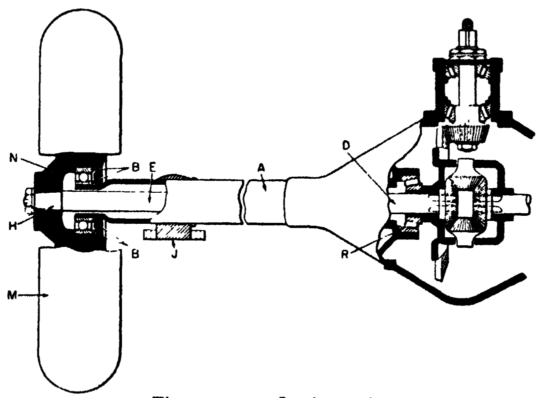
AXLE. An axle is a support for the rotation of wheels. In the dead axle, the wheel turns on the axle which is inserted in the hub portion, and forms the center of rotation. The contact surface between the wheel and the axle forms the bearing surface. In the live axle type the wheel is rigidly fixed to the axle which turns in bearings. The distinction between shaft and axle is this: a shaft is, in general, the support of



Full-floating axle.

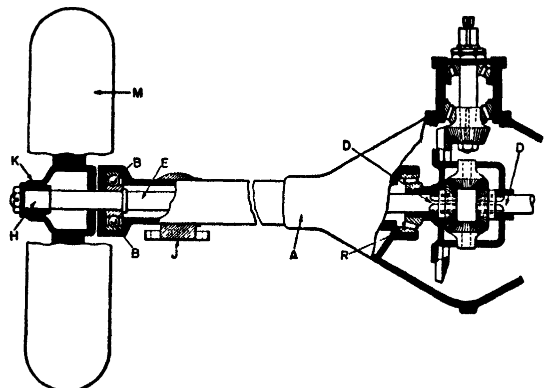
rotating objects, whereas axle is more definitely applied to a shaft used with wheels.

The powered axle of an automobile offers an example of the live type. Three types of axles are shown in the illustration. They are, respectively, the full-floating,



Three-quarter floating axle.

the three-quarter floating, and semi-floating axles. In the full-floating type the wheel is supported entirely on the axle housing, *A*, and the axle shaft, *E*, transmits **torque** only. The axle shaft, *E*, needs to be positively connected to the wheel, but not rigidly. The three-quarter floating axle has the wheel supported on one set of bearings on the axle housing, and the shaft *E* must be rigidly fixed in the hub of the wheel to maintain alignment. Except when rounding turns, or when on roads which are not level, the shaft transmits pure torque only. The semi-floating axle is rigidly fixed in the wheel, and the axle shaft rotates on bearings in



Semi-floating axle.

the axle housing. The axle shaft in this case is in bending as well as **torque**, since it must support all of the weight which is transferred to its wheel. (F.T.M.)

AXOLOTL. Amphibia, Urodela. A **salamander,** *Ambystoma tigrinum,* found near Mexico City which, although related to some of the terrestrial salamanders, retains its **larval** form throughout life, becoming sexually mature in this stage. Under experimental conditions the animal has been caused to undergo the usual **metamorphosis.** (A.W.L.)

AXON. Neuron.

AYE-AYE. Mammalia, Primates. A **lemur,** *Chiromys madagascariensis,* of Madagascar, resembling a squirrel in form, with large ears and a bushy tail. (A.W.L.)

AZALEA. Heath Family.

AZIDES. Hydrazoic Acid and Azides.

AZILIAN. Paleontology of Man.

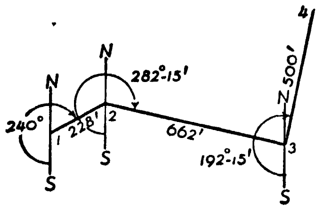
AZIMUTH. In astronomy, the azimuth of a celestial object is that coordinate of the **horizontal coordinate system** which is measured in the plane of the **horizon** to the point where the **vertical circle** of the object cuts the horizon. Astronomical azimuth is measured from the south to the right (west) through 360°.

Astronomical azimuth may be computed by solving the **astronomical triangle,** provided three other parts are known. In most cases the **latitude** of the observer, the **hour angle,** and **declination** of the object are the known parts. In case the **longitude** of the observer is not accurately known, the **altitude** of the object may be obtained and combined with latitude and declination for computing azimuth.

In **navigation,** azimuth is of great importance for the determination of **compass corrections** and for plotting **lines of position** from celestial objects. Navigators do not use astronomical azimuth, but instead the **bearing** of the object, which is the **direction** measured from the **north.** Tables are published by the various governments, and by private individuals, which give the bearing of the sun in terms of local **time,** date, and latitude; and the bearings of other celestial objects in terms of declination, hour angle, and latitude.

In surveying, terrestrial azimuth of a mark is usually determined with an **altazimuth** instrument or surveyor's **transit.** The difference in azimuth between the vertical circle through some celestial object and the mark is measured and combined with the known azi-

muth of the object to obtain the azimuth of the mark. The object most commonly used for this purpose is **Polaris** (the north star), since this star is within 1° of the pole of rotation and its azimuth changes very slowly with time. Tables are published in the Nautical **Almanac** and a variety of other places which give the azimuth of Polaris in terms of local date and time. When using the north star for ordinary surveying purposes, the local time is only needed to within about 5 minutes, but for precise geodetic work the time must be known to within a few seconds.



Course	Azimuth	Distance
1-2	240°	228
2-3	282°-15'	662
3-4	192°-15'	500

Plotting of a traverse.

Surveyors frequently **run a traverse** using azimuths and distances. The plotting of a traverse by this method is shown in the accompanying figure. (W.K.G.)

AZIMUTH CIRCLE. Alidade.

AZINES. Pyridine and Related Compounds.

AZO-, DIAZO-, AND RELATED COMPOUNDS. Compounds related to aniline, either directly or by oxidation, and to nitrobenzene, by reduction are numerous and important. (See **Aniline; Hydrazines; Hydroxylamines; Nitro-** and **Nitroso-compounds.**) Azo- and Diazo-compounds are considered here. See table at end of this article.

When **nitrobenzene** is reduced in the presence of **hydrochloric acid** by tin or iron, the product is aniline (colorless liquid); in the presence of water by zinc, the product is phenylhydroxylamine (white solid); in the presence of methyl **alcohol** by sodium alcoholate or by **magnesium** plus **ammonium** chloride solution, the product is azoxybenzene (pale yellow solid); by **sodium** stannite, or by water plus sodium amalgam, the product is azobenzene (red solid); in the presence of sodium hydroxide solution by zinc, the product is hydrazobenzene (pale yellow solid). The behavior of other nitro-compounds is similar to that of nitrobenzene.

Hydrazobenzene is converted by oxygen of the air or by ferric chloride solution into azobenzene, and by strong acids into benzidine hydrochloride ($(4')H_2N\cdot C_6H_4\cdot C_6H_4\cdot NH_2(4)\cdot HCl$). Benzidine is prepared by reducing nitrobenzene to hydrazobenzene as above, and then treating the product with acid. Benzidine and its toluene relative, orthotolidine, are important intermediates for dyes. The counterpart of aniline is toluidine in its three forms, ortho, meta, para.

Azoxybenzene is converted by distillation with iron into azobenzene (ferrous oxide also formed), and by concentrated sulfuric acid warm into para-hydroxyazobenzene ($(4)HO\cdot C_6H_4N{:}NC_6H_5$), which is a dye.

Diazonium salts are usually colorless crystalline solids, soluble in water, moderately soluble in alcohol, and when dry are violently explosive by percussion or upon heating. These salts are generally used in cold (near 0° C.) acid solution, without separation of the salt, and are prepared by reaction of the desired benzenoid primary **amine** with **nitrous acid** (from **sodium** nitrite plus **hydrochloric acid**). Alkyl amines with nitrous acid yield the corresponding alcohol.

(A) By treatment of benzene diazonium chloride $\left(\begin{array}{l}C_6H_5N—Cl\\ \quad\vdots\\ \quad N\end{array}\right)$ solution with **silver** oxide, or of the diazonium sulfate solution with **barium** hydroxide, the hydroxide (benzene diazo hydroxide, $C_6H_5N{:}N—OH$) is obtained, which is intermediate in basicity between ammonium hydroxide and sodium hydroxide. Most diazo hydroxides are unstable, and are spontaneously transformed into nitrosoamines (group $—NH\cdot NO$), yellow neutral compounds. With sodium hydroxide, diazonium salt solutions yield sodium benzene-diazoate, more active chemically when first formed than upon standing, due to change from syn-diazoate $\left(\begin{array}{l}C_6H_5N\\ \ddot{}\\ NaON\end{array}\right)$, which evolves nitrogen readily, to anti-diazoate $\left(\begin{array}{l}C_6H_5N\\ \quad\ddot{}\\ \quad NONa\end{array}\right)$ which is more stable. Sodium benzene-syn-diazoate reacts with phenols in alkaline solution to give **azo-dyes**, e.g., para-hydroxyazobenzene, wherein hydrogen para (or ortho but not meta) to the hydroxyl group is reactive. Other reactions of diazonium salts are:

(B) Replacement of the diazo-group with loss of **nitrogen**, (1) by hydroxyl-group, forming **phenols** by warming with water, (2) by alkoxy-group, forming ethers, by warming with an **alcohol**, (3) by acyl-group, forming **esters** with an acid, (4) by **hydrogen**, forming **hydrocarbons** or substituted hydrocarbons, e.g., tribromobenzenediazonium chloride forms tribromobenzene, with alcohol or sodium stannite solution, (5) by **chlorine**, forming, for example, chlorobenzene, by warming with **cuprous** chloride (Sandmeyer's reaction), (6) by **bromine**, forming, for example, bromobenzene, by warming with cuprous bromide (Sandmeyer's reaction), (7) by **iodine**, forming, for example, iodobenzene, by warming a solution of the diazonium iodide, (8) by **cyanide**, forming, for example, cyanobenzene, by warming with cuprous cyanide (Sandmeyer's reaction), (9) by fluorine, forming, for example, fluorobenzene, by warming a solution of the diazonium borofluoride. Gatterman's modification of Sandmeyer's reactions above is to use copper powder plus the corresponding sodium or potassium salt instead of the cuprous salt. Nitro-compounds, since they are readily reduced to the corresponding amine, form an important group of compounds for the preparation of various derivatives by means of the diazo-reaction.

(C) Reduction, to form the corresponding **hydrazine**, for example, benzene diazonium chloride to form beta-phenylhydroxylamine hydrochloride.

(D) Bromination followed by treatment with **ammonia** to form azides, for example, benzene diazonium bromide plus bromine forms benzene diazonium perbromide ($C_6H_5Br_3$), which upon treatment with ammonia forms phenylazide

$$\left(C_6H_5N\begin{array}{l}\diagup N\\ \quad\ddot{}\\ \diagdown N\end{array}\right).$$

(E) Amines, (1) primary or (2) secondary amine to form diazoamino-compounds, e.g., benzenediazonium chloride (a) plus aniline forms diazoaminobenzene, benzene diazoaniline ($C_6H_5N{:}N—NHC_6H_5$), (b) plus methylaniline forms benzenediazomethylaniline

$$\left(C_6H_5N{:}N—N\begin{array}{l}\diagup C_6H_5\\ \diagdown CH_3\end{array}\right).$$

Diazoamino-compounds readily change into aminoazo-compounds upon standing in alcohol solution or in the presence of amine hydrochloride, thus, benzenediazoaniline changes into para-amino-azobenzene, benzeneazoaniline-4 ($C_6H_5N{:}NC_6H_4NH_2(4)$), benzenediazomethylaniline changes into methyl-para-aminobenzene, benzeneazomethylaniline-4

$$\left(C_6H_5N{:}NC_6H_4N\begin{array}{l}\diagup H\\ \diagdown CH_3\end{array}(4)\right),$$

(3) tertiary amine to form aminoazo-compounds directly, e.g., benzenediazonium chloride plus dimethyl-

aniline forms dimethyl-para-aminoazobenzene, benzene-azodimethylaniline-4 $\left(C_6H_5N{:}NC_6H_4N\begin{smallmatrix}CH_3\\CH_3\end{smallmatrix}(4)\right)$. In this manner are prepared the azo-dyes, which contain the chromophore azo-group (—N:N—) plus an auxochrome amino-group $\left(—NH_2, —N\begin{smallmatrix}H\\CH_3\end{smallmatrix}, —N\begin{smallmatrix}CH_3\\CH_3\end{smallmatrix}\right)$. The simplest azo-dyes are yellow, but by increasing the number of auxochrome groups or by increasing the percentage of carbon, the color darkens to red, violet, blue, and in some cases brown. Naphthalene residues darken to red, violet, blue and finally black. These amino-azo-dyes, together with the hydroxyazo-dyes (containing auxochrome hydroxyl-group —OH), are generally only slightly soluble in water. In order that the dye may be soluble it is desirable that it contain one or more sul-

fonic acid groups ($—SO_2OH$). This group may be introduced either by treating the dye with concentrated sulfuric acid, or by using sulfonic acid derivatives in preparing the dye, e.g., methyl orange, sodium dimethyl-para-aminoazobenzene-para-sulfonate ((4) $(CH_3)_2N C_6H_4N:NC_6H_4SO_2ONa$ (4)) from dimethylaniline and diazotized sulfanilic acid (para-amino-benzene sulfonic acid, (1) $H_2N \cdot C_6H_4 \cdot SO_2OH$ (4)), and then the sodium salt made from the product. Other azo-dyes are

chrysoidine $\left(C_6H_5N:NC_6H_3\langle^{NH_2(2)}_{NH_2(4)}\right)$

Bismarck brown $\left((3)H_2N \cdot C_6H_4N:NC_6H_3\langle^{NH_2(2)}_{NH_2(4)} \cdot HCl\right)$

Congo red $\left(^{(4)HOO_2S}_{(1)\quad H_2N}\rangle C_{10}H_5N:NC_6H_4 \cdot C_6H_4N \cdot NC_{10}H_5\langle^{SO_2OH(4)}_{NH_2(1)}\right)$

(R.K.S.)

AZOLES. **Pyrrole and Related Compounds.**

AZOXY- COMPOUNDS. **Aniline; Azo-, Diazo- and Related Compounds.**

AZURITE OR CHESSYLITE. This mineral is a basic **carbonate** of copper, $2CuCO_3 \cdot Cu(OH)_2$ so called from its beautiful azure-blue color. It is a brittle mineral with a **conchoidal** fracture; hardness, 3.5–4; specific gravity, 3.77–3.89; luster, vitreous; color and streak, blue; transparent to translucent.

Azurite like **malachite** is a secondary mineral, but far less common than that mineral. It has been formed by the action of carbonated waters on compounds of copper or solutions of copper compounds, probably most abundantly by rich solutions reacting with limestones. Azurite almost always occurs associated with malachite. Found in Siberia, Greece, Rumania, at Chessy, France, whence the name Chessylite, in South West Africa, Australia and elsewhere. Azurite occurs in the United States at Bisbee, Arizona and Kelly, New Mexico. It is used as an ore of copper. (E.S.C.S.)

B

BABBITT. **Tin Alloys.**

BABBLER. Aves, Passeriformes. Birds (**Aves**) of the Ethiopian and Indian regions, particularly those of the family Crateropodidae but sometimes more loosely applied. (A.W.L.)

BABINGTONITE. This mineral is a relatively rare **calcium-iron-manganese** silicate, occurring in small black **triclinic** crystals, found in Italy, Norway and in the United States at Somerville and Athol, Massachusetts and in Passaic County, New Jersey. It was named for Dr. William Babington. (E.S.C.S.)

BABIRUSA. Mammalia, Artiodactyla. A wild **pig,** *Babirusa alfurus,* of Celebes with unusually long curved tusks, resembling the horns of some deer, which are the source of the name. Babirusa means pig-deer. (A.W.L.)

BABOON. Mammalia, Primates. The true baboons are characterized by the elongate, dog-like muzzle with nostrils at the tip. The head is large and they walk on all fours. These animals constitute the genus *Papio* but the term baboon is also applied to the gelada baboon, *Theropithecus gelada,* of southern Ethiopia, also a dog-like species although the nostrils are some distance from the tip of the snout. Baboons are also called dog-faced monkeys.

Among the baboons several species are known by special names, including the mandrill, *P. sphinx,* the drill, *P. leucophaeus,* and the chacma, *P. porcarius.* All are found in the Ethiopian region.

Baboons include some of the most hideous of animals and are correspondingly ferocious in disposition. Individually they are able fighters and their defenses are augmented by their habit of living in bands. A group of males is said to be a good match for some of the larger predators. (A.W.L.)

BACILLARY DYSENTERY. **Dysentery.**

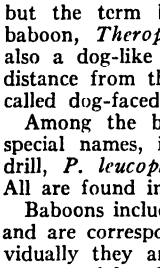
BACILLUS. **Bacteria.**

BACK BEARING. **Bearing.**

BACK-GOUDSMIT EFFECT. **Zeeman Effect.**

BACKSIGHT **Differential.**

BACK-SWIMMER. Insecta, Hemiptera. An aquatic **bug** of boat-like form which lives in an inverted position. The hind legs are broadened by fringes and are used like oars for propulsion. Family Notonectidae. (A.W.L.)



Back-swimmer.

BACTERIA, BACTERIOLOGY. Bacteria, often called germs or microbes, are microscopic unicellular organisms only obscurely related to other organisms. Their unicellular form, lack of definite nucleus, and method of reproduction by fission, remotely suggest relationship with blue-green **algae,** from which most are, however, distinguished by the absence of pigments. This lack of pigments leads many to connect them with **fungi.** The absence of chlorophyll (see **Pigments in Plants,** also **Aminoacids** and **Proteins**) makes it necessary for bacteria to obtain their nutritional requirements from organic sources. Many are parasites causing diseases of living plants and animals; others are **saprophytes** living on dead plants and animals, the chemical constituents of which are broken down by the action of the bacteria. Because of the results of their presence, bacteria, whether disease-producing or otherwise, are of tremendous importance to mankind.

The small size of bacteria makes them invisible to the unaided human eye. Although several early philosophers advanced the opinion that such invisible organisms must exist, it was not until the 17th century, with the invention of the **microscope,** that the Dutch lens-maker, Anton van Leeuwenhoek, actually saw these minute forms of life and reported them to the Royal Society of London, in 1683. After this the study of bacteria languished for a century. Throughout this early period little was known of the true nature of the organisms and the part they played in various processes, such as decay and **fermentation.** But during the 19th century the work of Pasteur definitely demonstrated the great biologic importance of bacteria.

The study of bacteria is closely connected with their culture, which means growing each form under such conditions as to exclude all other organisms, including other bacteria. To do this it is first necessary to clean thoroughly and sterilize all instruments and dishes to be used. Ordinary washing is insufficient. After thorough washing and rinsing, the dishes are covered or plugged with some substance which prevents the entrance of any solid particles, however small. A convenient material for plugging is ordinary cotton. All implements and vessels are next sterilized. This means exposure in an oven to a temperature as high as 170°–200° C. for 15 minutes or more, or treating with steam under pressure for 15 minutes or more at 120° C. If possible, such steam-pressure treatments are done in an autoclave. After sterilizing all objects to be used, it is necessary to prepare a suitable culture medium, which must be a substance on which the bacterium to be studied will grow satisfactorily. Many different media are used, such as meat broth and peptone, potato broth, etc. If gelatin is added, the medium becomes solid, and the organisms, growing on the surface, are more easily studied. However, the fact that gelatin liquefies at 37° C., and many bacteria grow best at higher temperatures, makes it desirable to find other substances which will remain solid at temperatures higher than 37° C. **Agar agar,** a vegetable product, is found to meet this requirement, and so is frequently used to prepare a solid medium on which to grow bacteria. The media are placed in suitably prepared dishes, sterilized, and then inoculated with the organism to be studied, precautions being taken to prevent the entrance of undesired organisms. On such solid media each species of bacterium forms characteristic masses or colonies.

Several methods are used for the study of bacterial cells. Living bacteria may be readily examined under the microscope by the hanging-drop method. To do this a drop of the culture, growing in a liquid medium, is transferred to a thin slip of glass (a cover slip) and inverted over a special glass slide in which a circular hollow has been ground. Bacteria grown on solid media may be transferred to a suitable liquid medium and mounted as a hanging drop. Such hanging drops allow one to study the living organism and to determine its motility, spore formation, and form.

Often it is desirable to study killed and stained bacteria. A thin film of bacteria is smeared on a clean glass slide and allowed to dry, after which it is fixed by pass-

ing through a flame, or by dipping in absolute alcohol, which is subsequently washed off. A suitable stain is then put on the smear of bacteria: gentian-violet is often used. After a few seconds the stain is washed off with water, and the preparation examined. Many methods of staining, some very elaborate, have been devised. One, known as Gram's method, merits description, since it is frequently used in describing bacteria. The stained organism is treated with an iodine solution and then washed in 95% alcohol; with this procedure many organisms give up the stain, and are said to be gram-negative; others retain the stain and are called gram-positive.

Bacteria are among the smallest of living organisms, varying from large species 1/250" in length to minute forms only 1/250,000" in length. The average dimensions of the species are 2 microns long and ½ micron in diameter (about 1/12,500" by 1/50,000").

Bacillus diphtheriae. Magnification 2250×.

The minute size of the bacterial cell makes it difficult to determine its structure accurately. In recent years, however, the electron microscope, which is capable of magnifications of over 200,000 diameters, has been a valuable instrument in the study of bacterial morphology. With its aid, a distinct cell wall of bacteria can be made out, inclosing the inner cell protoplasm. Within the **protoplasm** spheroidal or discoidal granules are seen in many species, as well as areas of decreased density. **Spores** form within the protoplasm of sporulating species. Nucleoprotein has been demonstrated under certain conditions in what has been interpreted as a simple **nucleus.** Surrounding the cell membrane of some species (notably pneumococci, and bacilli of the Friedländer group) a thin gelatinous sheath is present, forming a capsule. Flagella are organs of motility which are seen on the outer surface of motile bacteria; they are minute lash-like structures arranged singly, or in tufts at the ends of the cell, or in some species, covering the entire surface of the bacterium.

Reproduction in bacteria seems to occur solely by the process of fission, or **cell division.** This process occurs with great rapidity, often requiring less than a half-hour for completion, and occurring in many cases as frequently as once an hour. Simple calculation will show that under such conditions a single bacterium may give rise by successive divisions in a single day to many millions of cells, and in a few days to unbelievable numbers.

Such rapid divisions do not continue indefinitely, however. The nutrient supply may become exhausted, or the products of bacterial growth accumulate and become toxic, and divisions cease. Often such conditions bring about **spore** formation, each cell generally becoming a spore. A bacterial spore is highly resistant, surviving prolonged desiccation, intense cold or high temperatures, as well as the presence of harmful chemicals. Spores should therefore be considered not as reproductive bodies, but as a means by which the organism survives unfavorable conditions which would be fatal to the ordinary cell. Not all bacteria are capable of forming spores. Fortunately many disease-producing bacteria are of this less resistant type.

Bacteria may be classified into three families, according to the shape of the single cell. The first contains all those whose cells are spherical; these are known as coccus forms—the family is Coccaceae and includes the genera *Streptococcus, Staphylococcus,* and *Neisseriae.* A second family, the Bacteriaceae, comprises all forms having rod-shaped cells, which may be either straight or slightly bent. Such cells are known as bacillus forms. This family has three genera, *Bacterium, Bacillus,* and *Pseudomonas.* The third family, the Spirillaceae, is a small one, and contains those forms in which the cell is in the form of a spiral, known as a spirillum-form. While coccus forms do not possess cilia, most spirillum forms are ciliated. Bacillus forms may or may not have cilia, and so belong to either the genus Bacillus, or Bacterium, respectively.

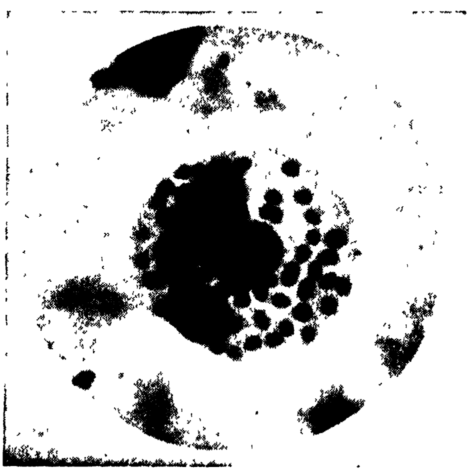
Bacteria may also be divided into two classes: **saprophytes** and **parasites.** Saprophytes are forms which grow and multiply best on dead tissue or organic matter, reducing it into simple chemical compounds which furnish food for plants, and thus, the saprophytes play an important part in the chemical cycle of living matter. They maintain the balance between the plant and the animal kingdoms. Ordinarily these forms do not cause disease in man unless potent toxins are produced by the bacteria. The parasitic forms live off the living tissues of higher forms of life and, in general, they form the group of pathogenic or disease-producing bacteria.

B. tetanus showing terminal spores. Magnification 1600×.

Another classification of bacteria is based on their source of nutrition. Organic compounds of all sorts may be a suitable nutrient source. Complex nitrogenous bodies are attacked and broken down by many, the process being the familiar one of decay and decomposition. Simpler organic substances are attacked by other species. Autotrophic bacteria are those which obtain the carbon necessary for **carbohydrate** formation from carbon dioxide and their energy from the oxidation of inorganic compounds, such as **ammonia, sulfur** and sulfur compounds, nitrites (see **Nitrous Acid**), etc. *Beggiatoa* is a genus of this group. Heterotrophic bacteria are those requiring organic sources of both carbon and energy for their existence. Nitrogen-fixing bacteria are examples of heterotrophic bacteria.

Like all living organisms, bacteria are affected by environmental conditions, particularly by temperature, light, moisture, oxygen supply and food requirements. Many bacteria are capable of growing under remarkable temperature conditions. Some, like the hay bacterium (*Bacillus subtilis*) can divide at temperatures from 6° C. to 50° C., while others, such as the pathogenic species, may have a very narrow range of temperature in which they can grow. Bacteria are less sensitive to low temperatures than to high ones.

Light is another very important factor in the life of bacteria: the germicidal action of direct sunlight is well-known. The action of light on bacteria seems due to oxidation processes which are fatal to the well-being of the cell. This fatal effect of light is confined to the ultra-violet region of the spectrum, and is found both in sunlight and also in electric light.



Gonorrheal pus showing the cocci within a leukocyte. Magnification 2250×.

Moisture is necessary for the continued existence of many bacteria: a short period of drying destroys a great many species in the vegetative phase, including fortunately most of the pathogenic forms. The spores of spore-producing forms are extremely resistant to desiccation.

Bacteria vary greatly in their oxygen requirements. There are many species which can exist only when free oxygen is available, such forms being known as obligate aerobes. Other species cannot exist except in the complete absence of free oxygen and are known as obligate anaerobes. Still other species are indifferent to the presence of oxygen and are called facultative anaerobes.

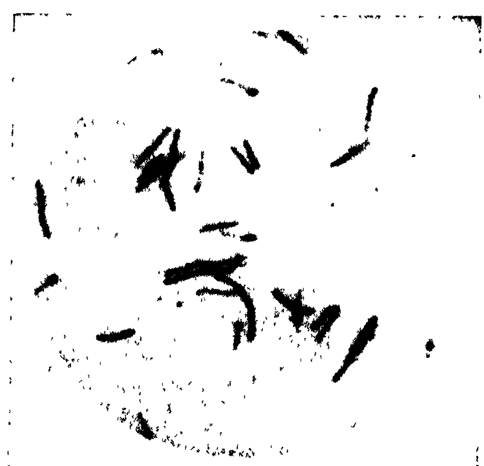
The importance of bacteria is tremendous. Of greatest significance to ordinary man are the many pathogenic species which, by their presence in the human body, cause disease. **Tuberculosis, leprosy, cholera, typhoid fever, diphtheria, pneumonia** and many other diseases are due to such organisms. Bacteria of this type are of highly specific nature, that is, can only attack a single host, or a small group of closely related hosts.

As bacteria may cause diseases in animals, so also are they the cause of many diseases in plants, although such diseases are not as numerous as those of animals. A common disease of plants which is caused by bacteria is Cucurbit Wilt, which appears in cucumbers, melons, pumpkins and squashes. In this case the bacteria gains entrance to the plant through wounds inflicted by insects such as the striped cucumber beetle. Once inside the plant body, the bacterium passes to the conducting strands of the stem, which are filled by the accumulating masses of rapidly dividing bacteria. These cut off the water supply of the leaves of the host plant so that wilting occurs and subsequently the death of the infected parts. A somewhat similar disease is found in Brown Rot of Tomatoes. Black Rot of Cabbage, Bean Blight and Crown Gall of many plants are all bacterial diseases of some importance.

The disease-producing bacteria are known so much better than are other forms of bacteria as to lead to the idea that bacteria are eminently destructive. This, however, is far from the truth. Probably the beneficial types of bacteria many times outweigh the injurious forms. Some of these beneficial forms are used by man in the industries. The souring of milk is caused by the presence in the milk of certain bacteria which result in the formation of **lactic acid.** Bacteria present in cream during its ripening cause the butter presently made to have certain flavors. Many cheeses owe their particular characteristics to the presence of certain bacteria. Molds also play a very great part in the development of the much-sought flavors (and also odors) in the many cheeses. The mold *penicillium notatum* produces a substance known as **penicillin** which has proved to be one of the most effective of the **antibiotics.** Its use in the treatment of certain bacterial infections has saved many lives.

In the tanning of hides and in the curing of tobacco, bacteria are thought to play an important part. The oxidation of **alcohol** to **acetic acid** in such weak alcoholic liquids as cider and wine is due to the activities of different species of bacteria. In the preparation of **flax** fibers and also **hemp** bacterial action is very important, for by their action the cement substance binding the fibers together is broken down and the fibers freed. The action of certain bacteria is important for the proper preservation of ensilage.

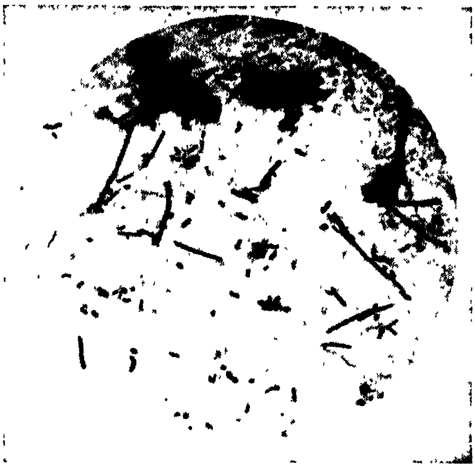
Of particular importance to man is a certain group of several different bacteria which occur normally in the



B. tuberculosis in sputum. Magnification 2250×.

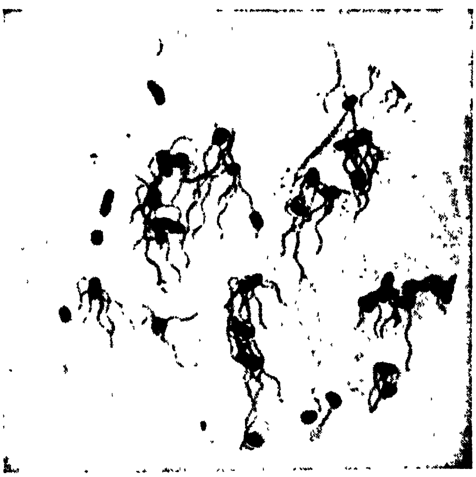
soil and are instrumental in making available to higher plants the very essential element **nitrogen.** All plants require a considerable amount of this element, which is available to them only in the form of certain soluble compounds, such as nitrates. The large percentage of free nitrogen in the atmosphere is unavailable, and few soils naturally contain a sufficient supply of usable nitrogen. Commercial **fertilizers** may be used to provide the necessary amount, but they are expensive. **Ammonia,** a product resulting from the breaking down of organic matter by bacterial action, is another possible source of nitrogen which is largely unavailable to higher plants. There are several species of bacteria which are able to convert ammonia into nitrates and other species which fix the free nitrogen of the air. These organisms are of very great importance to man. Their activities are collectively included in what is called the nitrogen

cycle, and fall in three groups, those comprising the nitrogen-fixing bacteria, the nitrifying bacteria and the denitrifying forms. The nitrogen-fixing bacteria, in turn, fall into two groups, those living free in the soil and those which enter the roots of various plants. By their activities the fertility of a soil is built up greatly without any attention from man. The free-living forms in the soil obtain the energy necessary for their existence from various organic compounds and assimilate free nitrogen of the atmosphere so that it is subsequently



Bacterial flora from the mouth showing rods and cocci. Magnification 850×.

available to higher plants. Several species of bacteria are included in this group, including *Clostridium pasteurianum* and *Azotobacter chroococcum,* and they are most abundant in light, well-aërated soils. The nodule-forming bacterium, *Bacillus radicicola,* normally occurs in the roots of various plants, particularly legumes, such as clover, alfalfa, vetch, etc., causing small lumps or nodules to form at various places on the root. The



Bacillus typhosus showing flagella. Magnification 150×.

bacteria are highly specific in the hosts they enter, each strain being restricted to a single species or to a small group of species. It is necessary, therefore, in spite of the widespread natural occurrence of the bacteria, to inoculate with the proper strain any new plant to be introduced. This is particularly noticed in the case of **Alfalfa,** where the seeds are covered with a suitable strain of bacteria before being planted. The bacterium enters the root through the root-hairs, a spot on the surface of the latter softening to permit their entrance. Once inside the cell, the bacteria pass inward into the **cortex,** where they accumulate in great numbers in the **vacuoles** of the cells. Their presence causes definite enlargement of the infected cells, thus producing the conspicuous nodules. Within the nodules the bacteria become modified into irregular, frequently somewhat branched objects known as bacteroids. In the presence of abundant energy-supplying **carbohydrates** from the host plant the bacterioids assimilate free nitrogen, which is built up into complex nitrogenous compounds. These are either utilized by the host plant directly or liberated into the soil on the death of the host plant, so adding to the fertility of the soil.

In addition to the various nitrogen-fixing forms described above there are other bacteria which make available to higher plants the necessary nitrogen. These are collectively known as the nitrifying bacteria, and are of two kinds. The first, *Nitrosomonas,* converts ammonia into nitrites, and the second, *Nitrobacter,* converts the nitrites into nitrates.

The ammonia necessary for the development of the nitrite-forming *Nitrosomonas* results from the activities of another complex and very important group of organisms, largely bacteria, known as denitrifying organisms. These bacteria reduce nitrates to nitrites and ammonia, to oxides of nitrogen or to gaseous nitrogen. More important in the formation of ammonia are the various organisms causing decay of the dead bodies of plants and animals. These attack the complex organic substances which occur in dead bodies and break them down into simpler forms, eventually into ammonia, oxides of nitrogen or even free nitrogen. The process is one of great complexity and occurs in many stages, each organism attacking a single substance and reducing it to simpler forms, which will in turn be attacked by other organisms until the lowest stage is reached. The great result of the activities of these organisms is the disintegration of what otherwise would accumulate as vast quantities of dead matter, in which large amounts of chemicals necessary for living organisms would be bound. Putrefaction is thus a very necessary process for the continuation of life. (R.S.M., R.M.W., D.M.H.)

"BAD LANDS." The literal translation of the phrase *Mauvais Terre* of the French explorers who so described the highly dissected, relatively unconsolidated **sandstones** and **shales** such as occur in the western Great Plains near the Black Hills. Small areas also occur in the plateaus of the Rocky Mountain region. This type of topography develops in arid and semi-arid regions where the underlying formations are relatively soft, and, due to the climate, are not protected by a plant cover. (R.M.F.)

BADGER. Mammalia, Carnivora. Stoutly built and short-legged burrowing animals of several species, found throughout the northern hemisphere. The term is extended to the ferret-badgers, which are related to the **skunks,** and to the **ratels** of India and Africa, which are called honey-badgers.

Badgers are courageous and able fighters when attacked and are sometimes hunted for sport, but they are peaceful animals unless molested. The fur is moderately valuable and the long hairs, especially of the European species, *Meles taxus,* are used in making brushes. Badger-hair shaving brushes are a familiar example. (A.W.L.)

BAFFLE. Mixing.

BAFFLES. In the engineering sense, a baffle is an object, usually a partition, placed for some specific purpose in the flow path of a fluid causing it to take some prearranged and circuitous path. Thus baffles are found in steam **boilers** to direct the hot gas properly back and forth over the tubes so that the gas will give up its heat to the required degree, and will not short-

circuit directly from the furnace to the stack. For this service the baffle is composed of refractory material similar to firebrick and will be found in longitudinal or transverse arrangement. Transverse baffling is made by building the baffle perpendicular to the tubes. Longitudinal baffles are usually precast and laid upon the tubes of the boiler, forming a baffle whose surface is parallel to the tubes.

Baffles are built in coagulation basins to impede the flow of liquid, and are also found in exhaust **mufflers** where their purpose is to mix the flow of gases in adjacent exhaust puffs that they may emerge from the muffler in a silent steady stream. (F.T.M.)

BAGASSE. In the manufacture of sugar (see **Carbohydrates**) from sugar cane the crushed fibers from which the sap has been expressed are called bagasse. Its principal use is as a fuel to run the mills which crush the cane. For this purpose bagasse is mixed with petroleum oil. It is also used as a fertilizer and to some extent in manufacturing heavy insulation board and coarse paper. (R.M.W.)

BAG-WORM. Insecta, Lepidoptera. The **larva** of a **moth** which is encased in a covering of silk mixed with bits of leaves, twigs, etc. Only the head and legs protrude from the bag, hence the insect appears to be suspended from the twig on which it walks. The adult females are wingless and the eggs are deposited in the silken bag.

One species of bag-worm sometimes does great damage to evergreen trees, especially the cedars, and so has been named the evergreen bag-worm, *Thyridopteryx ephemeraeformis*. The larvae can be killed by spraying infested trees with lead arsenate and the destruction of the bags in the winter, when they contain eggs, is an important measure of control.

These insects constitute the family Psychidae. (A.W.L.)

BAILY'S BEADS. During an **eclipse** of the sun, at the instant when the moon's edge is just tangent to the edge of the sun, i.e., at either second or third contact, the thin crescent of the disappearing sun suddenly breaks up into a number of brilliant spots known as Baily's Beads. These are produced because the surface of the **moon** is very rough, and mountains on the moon will completely cover the sun's disk while the sunlight is still coming to the earth through the valleys. (W.K.G.)

BAINITE. Steel.

BAKING POWDERS. Baking powders are used instead of leavening or **fermentation** agents to make light those baking products made mainly from **flour.** Baking powder, when it is mixed with flour and other ingredients and the resulting mixture is thoroughly moistened and heated, evolves a gas, **carbon dioxide** (sometimes **ammonia**), thus producing a light porous product. To supply carbonate for the production of carbon dioxide, **sodium** hydrogen carbonate ("baking soda," $NaHCO_3$) is universally used. To supply acid, three classes of materials are in common use: (1) **potassium** hydrogen tartrate ("cream of tartar," $KHC_4H_4O_6$), and infrequently, **tartaric acid** ($H_2C_4H_4O_6 \cdot H_2O$), (2) **calcium** dihydrogen phosphate (calcium monophosphate, $Ca(H_2PO_4)_2 \cdot H_2O$), (3) sodium **aluminum** sulfate ($Na_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$). The proportions (approximate only because it is customary to use some excess of carbonate) are, with one part by weight of sodium hydrogen carbonate, (1) 2.2 parts by weight of potassium hydrogen tartrate, (2) 1.0 of tartaric acid, (3) 1.5 parts of calcium hydrogen phosphate, crystallized, or (4) 1.8 of sodium aluminum sulfate or ammonium aluminum sulfate. With 7 parts by weight of this finely powdered mixture, there is usually mixed about 3 parts by weight of starch to diminish the effect of moisture in storage. In some cases, dry powdered egg albumin is added to decrease the loss of carbon dioxide upon wetting the flour and baking powder mixture when used. For some purposes **ammonium** carbonate ($(NH_4)_2CO_3$) is used alone, since, upon heating, this material furnishes both ammonia and carbon dioxide gases to make the product light. These gases escape from the product in the baking process.

The referee board of consulting scientific experts of the United States government, consisting of Ira Remsen, chairman, Russell H. Chittenden, John H. Long, Alonzo E. Taylor, and Theobald Smith, concluded (1914) after exhaustive experimental investigations, that alum baking powders are no more harmful than any other baking powders, but that it is wise to be moderate in the use of foods that are leavened with baking powder.

The Inland Revenue department of the Canadian government has since 1889 conducted periodical surveys of the quality of baking powders sold to consumers in Canada. The department regards 10% by weight of carbon dioxide as a minimum, and 12 to 13% as normal.

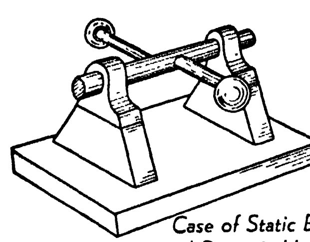
Date of Survey	Number of Samples in which Carbon Dioxide was Determined	Available Gas, Per Cent by Weight
1889	149	8.17
1908	158	10.24
1915	195	11.91

In 1917, the report stated for 185 baking powders purchased in the open market:

35 samples below standard (10% carbon dioxide)	
68 alum-phosphate samples	10.78%
46 cream of tartar samples	11.01
31 acid phosphate samples	11.25
5 alum samples	12.40

(R.K.S.)

BALANCE. Mechanical balance consists of the equilibrium of masses, and can be divided into static and dynamic balance. Static balance occurs in a system when the **center of gravity** of the system coincides with its reactions. For example, a rotating body in static balance has its center of gravity coincident with its axis of rotation. A system may, however, be in static balance, but become unbalanced when the system rotates. Such a system, for example, as that shown in the accompanying figure may well be in static balance,



Case of Static Balance and Dynamic Unbalance

and satisfactorily pass a balance test which would consist of putting the shaft on absolutely horizontal parallel rails and trying the rotor for equilibrium in any position. But when this system rotates, the centrifugal forces of the two weights, not being in the same plane perpendicular to the axis of rotation, create a couple acting on the shaft. That couple rotates with the shaft and produces shaking forces at the journals, and vibrations in the foundation. The dynamic balancing of this system would involve the addition of a system of counter balances which, by themselves, would be in static equilibrium, but which in rotation would produce a couple equal in magnitude but opposite in direction to the one already considered.

Dynamic balance is especially important in high-speed or heavy rotating machinery, as the vibrating forces are proportional to the mass and the square of the speed of rotation. Manufacturers frequently use balancing machines for testing their product when it is especially important that it be perfectly balanced.

Reciprocating balance consists of opposing the shaking forces of a reciprocating mass by equal and opposite forces obtained from another reciprocating mass. One particularly difficult job of balancing occurs in a system consisting of both rotation and reciprocation, as exemplified by the **piston, connecting rod,** and **crank** mechanism. The difficulty lies in the fact that if perfect balance is secured in the direction of reciprocation by the employment of rotating counter balances, severe unbalance will result in a plane perpendicular to that direction. The solution of this difficulty is a compromise in which only part of the reciprocating mass is counterbalanced, thus reducing the maximum degree of unbalance, but producing a smaller unbalance in two planes.

An electric network is in a condition of balance when so adjusted that an e.m.f. in one branch produces no current in another branch. This is the case, for example, in a properly adjusted **Wheatstone bridge.**

The balance is a well-known instrument used in weighing While any type of "scales" used for weighing may properly be called a balance, the term usually refers to the equal-arm balance familiar in every laboratory.

The dynamics of this instrument is relatively simple unless the pans are allowed to oscillate independently of the beam, a condition which should be carefully avoided while taking readings. The balance may then be treated as a gravity pendulum suspended from the central knife edge or pivot, the pans and their loads being regarded as concentrated at the end knife edges. Any slight excess weight Δw on one pan causes a change in the equilibrium position. The "sensitiveness" of the balance is appropriately expressed as the change in the equilibrium pointer reading per unit excess weight. More convenient in practical work is the reciprocal of the sensitiveness, which may be called the "stability." Thus if the change in pointer reading Δr is produced by a change of weight Δw on one pan, the stability is $s = \Delta w/\Delta r$. It is easily shown that unless the three knife edges are exactly in a straight line (which is seldom true), the stability not only depends upon the construction of the balance but is also a function of the load on the pans. If the load on each pan is W, the stability is expressed by a linear equation,

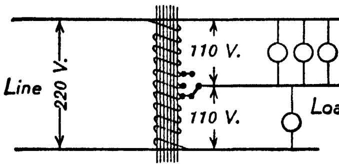
$$s = a + bW,$$

in which a and b are constants to be experimentally determined. The instrumental factors affecting the stability and upon which the constants a and b depend are: length of beam; relative lengths of pointer and of scale division; distances of central knife edge above center of mass and above or below line joining end knife edges; and total weight of moving parts, exclusive of load.

The pointer and scale are used in refined weighing to interpolate between the smallest weights in the set (commonly milligrams), for which purpose the value of s for the load on the pans must be known; it may be calculated from the above formula. Balances usually have also a rider scale, along which a small, hairpin-shaped weight may be moved to secure equilibrium, or to secure any desired pointer reading. The rider may be used in determining the stability constants a and b.

The arms of a balance, supposedly equal in length, are never exactly so. The result is that if the pointer stands at the zero of the scale with the pans empty, it will not do so when equal loads are placed on the two pans. This defect is compensated by the method of "double weighing." (See **Weighing Methods.**) (F.T.M., L.D.W.)

BALANCE COIL. A balance coil is a coil for supplying a three-wire circuit from a two-wire circuit. A 220-volt single-phase line, for example, can be used to supply two 110-volt circuits consisting of three wires, one of which is a common intermediate wire.



Balance coil for a.c.

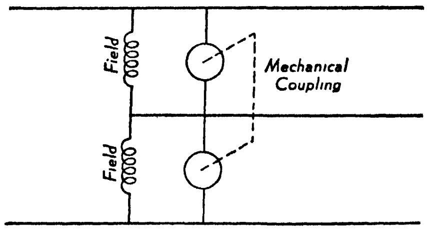
The voltage between the intermediate wire and either of the outside ones is 110 volts. If the loads on the two 110-volt circuits are unequal, the voltage can be balanced by an adjustment of the central tap point at the balance coil. A balance coil is frequently an **auto-transformer** having only one coil, a certain portion of which is used for both a high and low tension winding. The auto-transformer has connections at the ends of the coil, and an intermediate connection.

In d-c circuits the balance coil is used in conjunction with the **generator** to obtain a three-wire system. The generator windings are tapped at two diametrically opposite points and these taps are connected to the ends of a balance coil. The third wire for the system is obtained by connection to the center of the balance coil. Some manufacturers build the coil in the spider of the **armature** and bring out the center connection through a **slip ring** and **brush** while other manufacturers bring out the two tap connections on the armature through a pair of rings and brushes, mounting the balance coil outside the generator. (F.T.M., L.R.Q.)

BALANCED MODULATOR. A balanced modulator circuit is used to generate the **sidebands** of an amplitude modulated wave (see **Modulation**) and suppress the **carrier.** Since the power involved in a modulated wave is distributed at 100% modulation such that the carrier frequency component has ⅔ and each sideband ⅙ of the total, suppression of the carrier eliminates the necessity of supplying a major portion of the power usually needed. The output of such a modulator could be transmitted as only the sidebands, but in order to demodulate it a carrier wave would have to be introduced at the receiver. Such a system is known as a double sideband and suppressed carrier system. It is not used in practice because the carrier introduced at the receiver must have almost exactly the frequency of the one removed at the transmitter. Technical difficulties make this impractical. The balanced modulator output is normally fed through a filter circuit which cuts out one sideband and the other is transmitted. This gives single sideband, suppressed carrier transmission and is widely used, especially in **telephony,** since the frequency requirements for the carrier introduced at the receiver are not nearly so strict as the previous case. The reintroduced carrier needs to have an amplitude comparable to the received signal which is, of course, a small part of that needed at the transmitter of a radio system. The frequency band occupied by a single sideband, suppressed carrier system is somewhat less than half that needed for a full system. This is an important asset in telephone carrier circuits where the transmission line characteristics limit the total frequency band which can be transmitted. The single sideband system allows twice as many **channels** then on a given line. (L.R.Q.)

BALANCER SET. This consists of two shunt dynamos connected in series across a two-wire d-c distribution system to supply the third wire for a three-wire

system. Either machine may act as **motor** or **generator**, the action being determined by the direction of unbalance of the load. For unbalanced loads one machine



Balancer set.

motors and drives the other as a generator to tend to restore the voltage balance. (See Fig. 1.) (L.R.Q.)

BALANOGLOSSIDA. **Enteropneusta.**

BALANOGLOSSUS. A genus of worm-like marine animals belonging to the lower **chordates**. The name is also commonly applied to any of the similar animals of several genera. **Enteropneusta.** (A.W.L.)

BALAS RUBY. **Spinel.**

BALATA. **Gutta Percha; Belting.**

BALDNESS. **Alopecia.**

BALDPATE. Aves. 1. A North American **duck** *Mareca americana*. 2. A **dove** found in the West Indies. Both species are ineptly named from the white crown feathers. (A.W.L.)

BALL BEARING. **Bearings.**

BALLAST. Any material used for the purpose of providing stability is called ballast. Ballast is used in ships to bring the **center of gravity** of the vessel below a point called the **metacenter**, when there is a lack of cargo which would produce the same effect. **Balloons** and **airships** carry ballast which acts as a stabilizer and provides a means of controlling the rate of gain of rise as well as the altitude. Light vehicles which move at high speeds are often provided with ballast to lower the center of gravity and prevent overturning. Sand or water are very useful for ballast. Crushed stone which is placed under and between railroad ties to absorb impact and provide smooth riding conditions is also called ballast. (C.W.C., F.T.M.)

BALLAST TUBE. This is a resistance element sealed in a tube, usually in a hydrogen atmosphere, and is used as a series component of a circuit to maintain the current constant. This is accomplished by designing the ballast tube so the resistance increases and decreases rapidly with corresponding changes of current through it. (L.R.Q.)

BALLISTICS. This is the science which treats of the motion of masses projected into space, especially as associated with the motion of projectiles from guns and cannon. The complete path of a projectile is comprised of three separate and distinct phases. The first occurs in the bore of the gun, and the study of projectile motion here is that of interior ballistics. Secondly, there is the study of the path taken by the projectile as it flies through space from the gun to the target. This is exterior ballistics. Then, thirdly, there is the study of the penetration and the penetrating power of a projectile, which, for want of a better term, might be called penetration ballistics.

Interior ballistics is largely interwoven with the study of **thermodynamics**—the pressure, volume, and temperature of an expanding gas during travel of the projectile in the bore. It is concerned with the amount and combustion characteristics of gunpowder. The maximum pressures, and location of the same, stresses in the barrel, and the design of the barrel to resist these stresses, may also be said to be interior ballistics. The science of exterior ballistics might be said to have been rationally developed by Newton as a by-product of his study in **gravitation.** If the effect of air on the motion of a projectile is omitted, then the trajectory is **parabolic**, since as soon as the bullet or shell leaves the muzzle of the gun, force of gravity begins to pull it towards the earth. It is therefore impossible for a bullet to travel in a straight line, and if it is to return to a target at the same elevation as the muzzle, it must have an initial upward component given by aiming the barrel somewhat above the target. If the muzzle velocity is V, and the inclination of the barrel to the horizon is i, its upward component is $V \sin i$. If the action of gravity is wholly unresisted, the time it will take to reach the top of trajectory (at which point the upward component has been reduced to zero) is the same as that required by a freely falling body to attain a velocity equal to that of the vertical component at the muzzle. Assuming a simple case where the target is at the same level above the earth's surface as the gun, it would take another equal interval of time for the projectile to move from the top of its trajectory to the target. The distance to the target would be that covered by the horizontal component $V \cos i$ in the period of time taken by the projectile in reaching the top of its trajectory, and then returning to its original level.

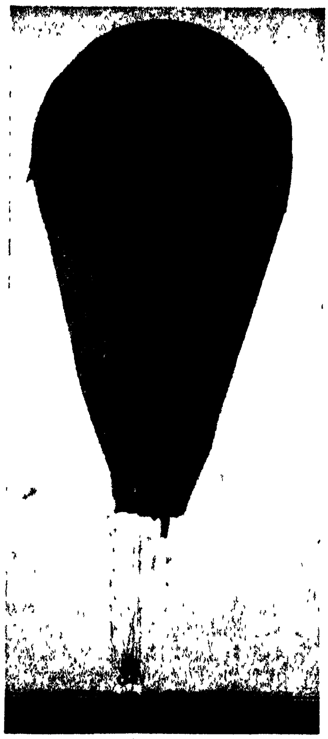
But the effect of air forces cannot be neglected, practically speaking, and the simple equations derived from the mechanics of a freely falling body are not applicable without considerable modification. The retarding effect of air, and the effect of winds, as well as other matters, are factors which must be taken into account in modern ballastics.

There is but little known in respect to penetration ballistics, and laws which relate to the depth and character of penetration of bullets and shells into armor are not well understood. Empirical formulae are relied upon greatly at the present time in the field of ballistics. (F.T.M.)

BALLOON. The balloon is a lighter-than-air craft receiving its sustention from the **buoyancy** of the gas it contains. It is non-rigid. The shape, usually spherical, is formed by the internal pressure of the lifting gas. The lifting medium first used was air which was expanded and made lighter than the atmosphere by heat. The hot air balloon was first devised by the Montgolfiers in 1783. At the present time **hydrogen** is the principal lifting gas. Balloons may be thought of as free or captive. The captive balloon has some military use for observation, or fire control, but until recently the free balloon had little or no value other than sporting. The national and international balloon races gave impetus to this use of the free balloon, and many amazing records were hung up by sportsmen balloonists. The balloon drifts with the wind, and may be sent aloft by releasing **ballast**, or brought down by valving off the gas from the balloon. A knowledge of the science of meteorology is important in racing balloons, and there is a great deal of highly specialized knowledge required in connection with the operation of the balloon. Happy combinations of skill and weather conditions have enabled flights of more than 1000 miles to be made.

In recent times a new and scientific use of the free balloon has appeared. Several flights to the **stratosphere** have been made by specially-built balloons. The flights of these balloons to high levels may serve to advance scientific knowledge of cosmic rays and to study atmospheric conditions in the stratosphere. This information may become useful commercially. The problems

of stratosphere ballooning are highly specialized, and the equipment quite expensive; consequently, stratosphere ballooning is undertaken largely by societies or governmental departments. Professor Picard of Belgium was one of the pioneers in this field, and ascended to over 60,000′. Whereas a racing balloon has a volume of some 80,000 cu. ft., the stratosphere balloons contain, when fully inflated, over ten times this volume. This extremely large volume is necessary in order to obtain sufficient buoyancy to lift the useful load to the stratosphere, where the atmosphere itself is very thin. Stratosphere ballooning is exciting, dramatic, and dangerous. It has



Balloon.

already taken its toll of human life, but has created one of the most thrilling modern chapters of the history of science.

In the winter of 1933 three Russians ascended to an unofficial height of 72,000′. Unfortunately, these intrepid men were killed during the descent, and no official mark was set. In the fall of 1934 Captains Stevens and Anderson and Major Kepner, of the United States, had a narrow escape from death. Having ascended to nearly 60,000′, they were in the process of a normal descent when their balloon split at 5000′. Fortunately, all men parachuted safely to the ground, although the last man to leave was perilously low before clearing the gondola, which plummeted to the ground, destroying most of the scientific instruments carried. However, in November, 1935, Captains Stevens and Anderson again ascended, and this time to a new world's record. Leaving the ground at 7 A.M., they climbed to 73,000′ in four hours, and obtained a great deal of scientific information on stratosphere photography, radio transmission, spore distribution, and air composition. Cosmic rays and the spectral distribution of sunlight were also studied during the hour or more that the stratosphere balloon (now being called stratostat) remained at the record height. During much of the remainder of the day the crew was busy governing the descent until the balloon was once again safely on the ground. In this case all instruments were intact and records were safely preserved. To give an idea of the construction of a stratostat, the Explorer II used by Captains Stevens and Anderson had a volume of 3,700,000 cu. ft. fully extended, and this was used to lift a tiny globe-shaped gondola made of monel metal, just large enough to contain the two observers and their equipment. The globular shape is used because it must be sealed and made air-tight so that life will be possible in the stratosphere where the normal atmosphere would be almost instantly fatal. The globe is the best shape for resisting the bursting pressure of the air contained within. At the start of the ascent some 250,000 cu. ft. of **helium** were put into the Explorer II, and as it ascended the bag filled out as the air pressure outside grew less. (F.T.M.)

BALSA WOOD. *Ochroma Lagopus.* Bombacaceae. Balsa wood is obtained from a South American tree, *Ochroma Lagopus.* This wood is composed largely of wood **parenchyma,** a tissue characterized by thin-walled cells. Balsa wood is almost colorless and very light, having a specific gravity of 0.2, which is less than that of cork. The light porous nature of this wood leads to its use in life-preservers and floats, as an **insulating** material, and in the construction of airplane models and special furniture. (R.M.W.)

BALSAM. **Resins.**

BAMBOO. Gramineae. The tribe *Bambusae* comprises grasses which are particularly important in Oriental countries. The plants included in this group are of extremely variable nature, ranging from small inconspicuous species to the largest species of grass known, some having slender erect stems approaching a hundred feet in height. Many are clambering vines which form dense impenetrable masses. All these grasses are characterized by jointed hollow stems having solid nodes, familiar to Western people in the common bamboo fish pole or the fairly rare broomstick. Among the Eastern peoples, bamboo is much more commonly used. The hollow stems may serve as pipes for conducting water, or as containers for storing water and other substances. Split stems may be flattened and used in constructing shelters, or boats, or furniture. Some species yield a fibrous material which is used to manufacture a kind of paper. The young stalks of certain species become an important foodstuff. Indeed, in some regions the people have come to depend almost entirely on bamboo, so numerous are its uses. (R.M.W.)

BAMBOO RAT. Mammalia, Rodentia. Any member of several species of burrowing **rodents** of the Oriental and Malayan region, related to the mole rats but with the small eyes exposed and with a short tail. (A.W.L.)

BANANA. *Musa paradisiaca.* Musaceae. The banana plant is a striking tropical plant found wild in the Old World tropics. About thirty species are known. The plant has a thick underground **rhizome** from which rises what seems to be a thick erect stem. Actually this false stem is formed by the leaf bases which grow wrapped together to a height of 10′. From the upper portion, the large leaf blades spread out conspicuously, sometimes to a length of 10′. Up through the center of the tube formed by the leaf bases the flower stem pushes its way and bears bunches of inconspicuous small tubular flowers in the axes of large showy **bracts.** After fertilization of the flowers, the bracts fall off, and the whole cluster gradually hangs over due to the weight of the developing fruit. When green the banana fruit contains an abundance of starch, some of which changes to sugar as the fruit ripens. The banana was introduced at an early period into the New World tropics, where it has now become one of the most valuable crops. The banana is related to the **plantain.** (See **Parthenocarpy.**) (R.M.W.)

BANANA-QUIT. **Honey Creeper.**

BAND SPECTRUM. **Molecular Spectrum.**

BAND SPREAD. In the finer grade of radio **receivers,** such as used for communications purposes, it is desirable to be able to tune rapidly over a wide frequency range, yet be able to tune carefully to rather fine limits over a small range at any selected point in the wider range. This is accomplished by the band spreading tuning provided on such receivers. The usual arrangement is to have the wider range covered by conventional tuning **condensers,** but have these paralleled by small variable condensers which are tuned by the band spread dial. Thus the complete range can be covered by one rotation of the main condensers, while for any point at which they may be set the smaller ones can be used to give fine variation, thus giving, in effect, a spread-out tuning scale at this point. Sometimes other special circuit arrangements, such as tapping a condenser across part of the tuning coil, are used to give the same result. (L.R.Q.)

BANDED ANTEATER. **Dasyure.**

BANDICOOT. Mammalia, Marsupialia. Medium or small burrowing animals of the Australian region, related to the kangaroos but stoutly built and quadrupedal There are several species of the genus *Perameles.* (A.W.L.)

BANDSAW. **Woodworking; Saw.**

BANK. 1. The position of an airplane when its lateral axis is inclined to the horizontal. A right bank is the position with the lateral axis inclined downward to the right. 2. To incline an airplane laterally, i.e , to rotate it about its longitudinal axis. (F T.M.)

BANKET. A Dutch term originally applied to the gold-bearing **conglomerates** of the Witwatersrand, South Africa. (R.M.F.)

BANNER CLOUDS. **. Clouds.**

BANTAM. Aves, Galliformes. A small variety of the domestic fowl. Sebright bantams, the best-known breed, are characterized by the similarity of the sexes. (A.W.L.)

BANTING. Mammalia, Artiodactyla. The Javan **ox,** *Bibos sondaicus,* a species which also occurs in other East Indian islands and in India and the Malay Peninsula. Domesticated herds are kept in part of its range. (A.W.L.)

BANYAN. *Ficus benghalensis.* Moraceae. The banyan trees of India, sacred to the natives of that country, are of interest because of their habit of sending down from the spreading branches aerial roots, which enter the ground and increase in size until they resemble trunks. A single tree may have scores or, exceptionally, even hundreds, of these trunks, which enable it to spread out over a tremendous area. It has been stated that Alexander and his army of men took shelter under a single extensive banyan tree. (R.M.W.)

BAR CHART. A method of representing relative magnitudes by lines or bars the lengths of which are proportional to the quantities involved. Simple barographs show individual quantities; compound barographs show complete quantities on a single bar, and are often referred to as percentage bar charts. (H.C.H.)

BARABOO. A baraboo is a hill, mountain or other eminence which was once buried by the deposition of **sedimentary** material about it and has since been exposed by the erosion of the younger beds. It is named from Baraboo, Wisconsin. (E.S.C.S.)

BARB. One of the divisions of a **feather** which branches from the shaft to form the vane. (A.W.L.)

BARBASTELLE. Mammalia, Chiroptera. A small European **bat** related to the California cave bat and to a few African and Asiatic species. Only one of the related species, the Himalayan barbastelle, receives the same name. (A.W.L.)

BARBEL. 1. Pisces, Teleostei. *Barbus.* Any of numerous species of fishes (**Pisces**) of the Old World, related to the carps. 2. A form of slender appendage found on the head in certain fishes and turtles, well illustrated by the **catfishes.** (A.W.L.)

BARBERRY. Berberidacae. The barberries are shrubby plants growing wild in the northern hemisphere, and also in South America. Many of them are spiny plants which are often cultivated as hedge plants. Examination shows that the leaves may vary from entire spiny-toothed structures to those reduced entirely to spines, only their position on the stem revealing the fact that they are leaves. The plants bear **racemes** of yellow flowers and later small red, yellow or black berries which make them very attractive. **Pollination** in barberries is rather interesting. Each of the six stamens (see **Flower**) has a spot at the base of the filament sensitive to touch. When an insect, pushing about the base of the flower in search of nectar, touches this spot, the stamen moves violently, so that the sides of the insect's head are powdered with pollen. When the insect visits another flower some of this pollen may be caught by the stigma, pollination then being completed.

One species of barberry, *Berberis vulgaris,* is the alternate host of *Puccinia graminis,* the organism causing the destructive disease of wheat **rust.** (R.M.W.)

BARBET. Aves, Piciformes. Birds (**Aves**) of several species intermediate between the **woodpeckers** and **toucans.** They occur in the tropical regions of both Old and New World and some species are brilliantly colored. The name was formerly applied to other members of the order found in tropical South America which are now known as puff-birds. (A.W.L.)

BARBITAL (Veronal). A commonly used drug which is effective as a **sedative, hypnotic,** and anticonvulsant. It is used in insomnia, hyperthyroidism, **chorea** and **epilepsy.** Other barbiturates are now more frequently prescribed. These are phenobarbital and the pentobarbitals. These drugs are more potent than simple barbital. The pentobarbitals have the advantage of acting rapidly; hence they are particularly useful in insomnia.

Poisoning with overdoses of barbiturates is common and suicides are frequently committed with these drugs. The acute intoxication is characterized by coma and depressed respirations. Death may be caused by paralysis of the respiratory center or vascular collapse. Chronic barbiturism causes lethargy, drowsiness, dizziness, and sometimes difficulty in walking and speaking. Withdrawal of the drug alleviates the symptoms completely. (D.M.H.)

BARCHAN. **Dune.**

BARITE. The mineral barite is **barium** sulfate, $BaSO_4$, crystallizing in the **orthorhombic system.** May occur as tabular crystals, in groups, or lamellar, fibrous and massive. Barite has two perfect cleavages, basal and prismatic; hardness, 2.5–3.5; specific gravity, 4.3–4.6, which has led to the term heavy spar, occasionally used for this mineral. Its luster is vitreous; streak, white; color, white to gray, yellowish, blue, red and brown;

transparent to opaque. Sometimes yields a fetid odor when broken or when pieces are rubbed together, due probably to the inclusion of carbonaceous matter. Barite is a frequently occurring gangue mineral and is found also in large masses in **sedimentary** rocks. Its name, barite, is derived from the Greek word meaning heavy. It is used as a source of barium compounds.

Barite localities are widespread, including many European occurrences, Czechoslovakia, Germany, France, Spain and England. In the United States barite is found in New York, Connecticut, Pennsylvania, Virginia, Michigan, Missouri, New Mexico, Oklahoma, Utah, Colorado, South Dakota, Georgia and Tennessee. In Canada it occurs in Ontario and in Nova Scotia. (E.S.C.S.)

BARIUM. Symbol: Ba. Atomic number: 56. Atomic weight: 137.36. Density: 3.5. Melting point: 850° C. Boiling point: 1140° C. (**Isotopes:** page 290.)

Barium is a silver-white metal, harder than lead, oxidizes rapidly in moist air, reacts with water yielding barium hydroxide and hydrogen gas, burns when heated in air, emitting a brilliant light and forming barium peroxide. Discovered by Scheele in 1774 and isolated by Davy in 1808.

Barium occurs chiefly as sulfate (**barite,** barytes, heavy spar, $BaSO_4$), and, of less importance, carbonate (**witherite,** $BaCO_3$). Georgia and Tennessee are the principal producing states. The sulfate is transformed into chloride, and the electrolysis of the fused chloride yields barium metal. Barium metal has been recently used as a "getter" in radio tubes, and as a nickel-barium alloy in automobile ignition systems.

Acetate Barium acetate ($Ba(C_2H_3O_2)_2$), white crystals, soluble, by reaction of barium carbonate or hydroxide and **acetic acid,** and then crystallizing

Carbide Barium carbide (BaC_2), black solid, by reaction of barium oxide and **carbon** at **electric furnace** temperatures, decomposes water yielding **acetylene** gas and barium hydroxide.

Carbonates: Barium carbonate ($BaCO_3$), white solid, insoluble, (1) by reaction of barium salt solution and **sodium** carbonate or bicarbonate solution; (2) by reaction of barium hydroxide solution and **carbon dioxide,** excess carbon dioxide forms barium bicarbonate ($Ba(HCO_3)_2$), solution and this by boiling yields barium carbonate. Decomposes at 1450° C.

Chloride· Barium chloride ($BaCl_2 \cdot 2H_2O$), white crystals, soluble, by reaction of barium carbonate or hydroxide and **hydrochloric acid,** and then crystallizing.

Chromate: Barium chromate ($BaCrO_4$), yellow precipitate, by reaction of barium salt solution and **potassium** chromate solution.

Cyanamide: Barium cyanamide ($BaCN_2$) mixed with **cyanide** ($Ba(CN)_2$), by heating barium carbide at 800° C. with nitrogen gas. Fusion of this cyanamide-cyanide mixture with sodium carbonate converts entirely to cyanide.

Hydride: Barium hydride (BaH_2), white solid, by heating barium metal or amalgam in **hydrogen** gas at 1170° C., reactive with water yielding barium hydroxide and hydrogen gas.

Hydroxide: Barium hydroxide ($Ba(OH)_2$), white solid, (1) by reaction of barium oxide and water, (2) by precipitation of barium salt solution with **sodium** hydroxide solution, yields ($Ba(OH)_2 \cdot 8H_2O$) on crystallizing, decomposes upon heating at about 850° C. to form oxide (BaO) and water.

Nitrate: Barium nitrate ($Ba(NO_3)_2$), white crystals, soluble, by reaction of barium carbonate or hydroxide and **nitric acid,** and then crystallizing, used in pyrotechnics for the production of green light.

Oxides: Barium oxide (BaO), white solid, melting point about 1900° C., reactive with water to form barium hydroxide; barium peroxide ($BaO_2 \cdot 8H_2O$), white precipitate, by reaction of barium salt solution and hydrogen or sodium peroxide, yields anhydrous barium peroxide (BaO_2) upon heating at 100° C. in a current of dry air. Anhydrous barium peroxide is also formed by heating barium oxide in air or **oxygen** under pressure (at somewhat over one atmosphere pressure) and temperature of 400° C. there is transformed into peroxide with air 70%, with oxygen 95%, of the total barium oxide taken. This reaction was applied in the Brin process for separation of oxygen from air, first forming the peroxide, and later heating the same to a higher temperature when oxygen was evolved and barium oxide remained for use again.

Oxalate: Barium oxalate (BaC_2O_4), white precipitate, by reaction of barium salt solution and ammonium **oxalate** solution.

Sulfate: Barium sulfate ($BaSO_4$), white precipitate, by reaction of barium salt solution and **sulfuric acid** or **sodium** sulfate solution, insoluble in acids, by heating with carbon yields barium carbonate. Present in a mixture with zinc sulfide, known as lithopone, a paint pigment, formed by the reaction of barium sulfide and zinc sulfate in water, followed by filtration and drying. The mineral barite when powdered is used as a paint pigment, as a filler for rubber goods, paper, and linoleum, only source of all barium containing substances.

Sulfides: Barium sulfide (BaS), grayish-white solid, by heating barium sulfate and **carbon,** reactive with water to form barium hydrosulfide solution; barium hydrosulfide ($Ba(SH)_2$), solution, (1) by reaction of barium sulfide and water, (2) by saturation of barium hydroxide solution with **hydrogen sulfide;** barium polysulfides are formed by boiling barium hydrosulfide with **sulfur.**

Volatile compounds of barium, such as the chloride, color the bunsen flame green. (R.K.S.)

BARK. All tissues of woody stems or roots which occur outside the **cambium** are collectively known as bark. In the earliest stages of its development, the **stem** is covered by a layer of thin epidermal cells, which may persist for some time. With increased age and growth, however, this epidermal layer is lost, and a new tissue is formed, either from the epidermal cells or from those cortical **cells** just beneath the epidermis. The cells which form this new protective layer are the cork cambium cells. The tissue which is formed by them is often called the cork or outer bark. If the divisions of the cork cambium cells occur fast enough the bark will remain smooth for some time. In most cases, however, an internal cork cambium forms in the deeper cortical tissues, and by producing secondary cortical tissue in isolated patches leads to the development of scales or patches of bark, with ever-deepening fissures as growth continues. In a few cases, as in the beech tree, the smooth condition persists throughout the life of the tree. In all young stems the continuity of the surface is broken by patches of loose cells, the lenticels, which permit an exchange of gases through the bark. The inner bark consists of phloem or bast, the food-conducting tissue of the plant. (B.S.M.)

BARK BEETLE. Insecta, Coleoptera. A small **beetle** of cylindrical form which burrows in the sapwood and inner bark of trees and logs, forming characteristic patterns. This habit also gives the name engraver beetle to these insects. Most of the numerous species infest forest trees but a few attack fruit trees. Together with the timber beetles and a few species which attack herbaceous plants they make up the family Scolytidae. (A.W.L.)

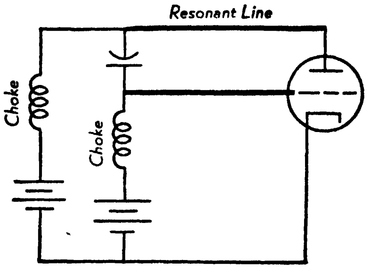
BARK LOUSE. Insecta, Homoptera. A scale **insect.** These insects are minute creatures with sucking mouths. They spend most of their lives attached to the leaves, stems, or roots of plants. The name scale insect is due to the common secretion of a scale which conceals the

body of the insect. There are many species, of which some, like the oyster-shell bark louse, *Lepidosaphes ulmi*, and the San Jose scale, *Comstockaspis perniciosa*, are important enemies of fruit trees. Spraying with lime-sulfur and kerosene emulsion is a common method of control, and fumigation with hydrocyanic acid gas is extensively practiced in the citrus groves of California. Sprays can be used more effectively when trees are dormant in winter.

Some scale insects produce substances of commercial value, notably cochineal and shellac. (A.W.L.)

BARKHAUSEN EFFECT. A series of minute "jumps" in the magnetization of iron or other ferromagnetic substance as the magnetizing force is continuously increased or decreased; discovered by H. Barkhausen in 1919. The effect may be observed by winding on the specimen, along with the magnetizing coil, a secondary coil connected to some sensitive detector of current fluctuations, such as an **oscillograph** or an audio amplifier. As the magnetizing current is steadily increased, the current in the secondary circuit, instead of being constant, exhibits a succession of small, sharp peaks or maxima, which the amplifier reveals by a faint clicking or snapping sound. These discontinuities in magnetization are interpreted as indicating the existence in the ferromagnetic material of elementary magnets, called "domains," which are much larger than atoms, but not large enough to be identified with individual crystals. Another possible interpretation is that the discontinuties are caused by the accidental coincidence of orientations in elementary magnets of much smaller size, somewhat as the **Brownian movement** of a particle is caused by the accidental impact of many molecules upon it simultaneously. (L.D.W.)

BARKHAUSEN OSCILLATOR. This is a type of vacuum-tube **oscillator** which depends upon the **transit time** of the **electron** across the tube for its operation. The conventional oscillator operates well at frequencies low enough to make the transit time negligible compared to a period of the alternation. As the frequency is increased this condition can no longer be met and such oscillators become less and less satisfactory until they fail altogether. Fig. 1 shows in principle, a Barkhausen oscillator. The plate is maintained at a slightly lower

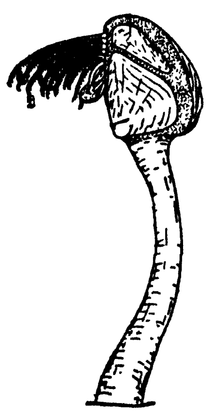


Simple Barkhausen oscillator.

d-c potential than the cathode, while the parallel wires serve as a tuned circuit to which the electrons deliver energy. An electron starting from the cathode is accelerated by the positive grid voltage until it passes the grid, then is decelerated by the negative plate, reverses and goes back by the grid, then is again reversed in the grid cathode space and repeats until it finally hits an electrode and is removed. The electron thus oscillates about the grid. If the phase of these oscillations of the electron is correct with respect to the oscillations in the parallel line system, the electron delivers energy to the system. Fortunately the operation of the circuit is such that those with wrong phase are rapidly removed. However, the efficiency of the circuit is low. The frequency is determined largely by the tube dimensions and the voltages applied, although other factors have a slight effect. (See **Klystron.**) (L.R.Q.)

BARLEY. *Hordeum vulgare* and *H. distichon.* Gramineae. Barley is a cereal **grass** with stalks up to three feet in height, and with the inflorescence a close spike. Many varieties are grown in cultivation, all probably derived from plants growing native in Asia. In the older varieties the flower possessed stout barbed **awns**, which were very disagreeable to those who handled the grain, and often the cause of serious trouble when the grain was fed to livestock. In the newer varieties, originating in Russia and widely cultivated and improved in the United States, these awns have been lost, leaving a smooth-fruited variety. In the mature barley grain the **aleurone** layer is usually three cells in thickness; the **embryo** is very small; and there is no **gluten.**

Primitive man in Europe used barley for food, as do many modern races. However, lacking gluten, it is impossible to make light bread from barley, a fact which prevents it from being popular with cultured races. It is frequently used in soups, and in the manufacture of breakfast cereals. Large quantities of the smooth grain are used as stock food. Its principal use, however, is in the manufacture of malt. For this purpose the grain is first soaked in water for 2 days or more at a temperature of about 55° F., with frequent changes of water to prevent excessive development of **bacteria.** The soaked grain is then spread out on the floor for twelve days, during which time **fermentation** occurs and germination starts. **Enzyme** action causes the starch (see **Carbohydrates**) of the grain to change to sugar. Before germination has led to a well-developed **coleoptile,** the grain is heated to stop growth and to drive off excessive moisture, which is reduced to about 2%. The sprouts are then removed and the malt, a pasty mass rich in starch and the enzyme diastase, is ready for use, principally in the manufacture of beer. (R.M.W.)



Barnacle.

BARNACLE. Crustacea, Cirripedia. **Sessile** marine animals wholly unlike the more common **crustaceans** in appearance. Some are parasitic, some burrow in the shells of marine animals, and some attach themselves to submerged objects. The last habit is economically important since it results in the fouling of ships' bottoms and entails the expense of periodical cleaning. (A.W.L.)

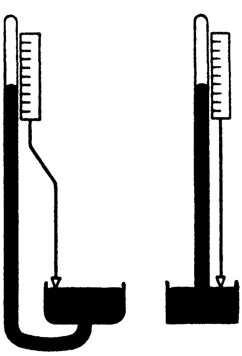
BARNETT EFFECT. In 1915, S. J. Barnett discovered that a relatively long iron cylinder, when rotated at high speed about its longitudinal axis, developed a slight magnetization, the value of which was proportional to the angular speed. He found the magnetization to be about 1.5×10^{-6} c.g.s. electromagnetic unit per revolution per sec. for a cylinder about 7 cm. in diameter and 50 cm. long. The effect was attributed to the influence of the impressed rotation upon the revolving electronic systems within the atoms. The suggestion has been made that the magnetic moment of the earth and of the sun may be due in part to the rotation of these bodies. An inverse effect was discovered about the same time by Einstein and de Haas; viz., an iron cylinder, suspended vertically, was observed to rotate slightly when suddenly magnetized. (L.D.W.)

BAROCLINIC. When isobaric surfaces and equal-density surfaces do not coincide the atmosphere is said to be baroclinic. If the surfaces do coincide, the atmosphere is said to be barotropic. Local winds often arise when the atmosphere is highly baroclinic. (P.E.K.)

BAROGRAPH. A recording **barometer**, commonly of the aneroid type. The pressure-sensitive unit consists of a pile of several elastic-walled evacuated boxes, connected through a suitable linkage to the stylus-arm, which carries the pen up and down on a slowly revolving drum. The variations of atmospheric pressure are thus traced on the paper, usually ruled in days and hours for the period of one week. Such instruments are extensively used by the U. S. Weather Bureau at its many observation stations. (See **Meteorological Instruments; Bar Chart.**) (L.D.W.)

BAROMETER. The barometer owes its origin to Torricelli, who, in 1643, first utilized a column of water to measure the atmospheric pressure and its variations. The obvious disadvantages of a barometer tube 34 feet long, with water vapor pressure above the liquid, soon brought about the substitution of mercury. This reduces the necessary length of the instrument to about 3 feet over all; and the vapor pressure of mercury at ordinary temperatures is negligible. To set up a mercurial barometer, one needs only to fill a clean glass tube, closed at one end, with pure mercury, heat it to expel air, and invert it in a small cup of freshly boiled mercury. At normal pressures the column will sink to about 76 centimeters, leaving a "Torricellian vacuum" above it. The scale must be made adjustable so that its zero may always coincide with the surface of the mercury in the cup. In some barometers the mercury is contained in a leather bag tied to the lower end of a short glass cylinder, making it possible to raise or lower the mercury level by a screw compressing the bag. The readings must of course be corrected for variations of temperature.

The aneroid barometer is merely a delicate pressure gauge, consisting essentially of a round, flat, air-tight,



Two types of mercurial barometer (diagrammatic).

evacuated metal box, with elastic bases which respond to variations in pressure by springing in and out, and the movements of which are communicated to a pointer on a graduated dial. Such barometers are portable and quite sensitive, and are much used on shipboard, in airplanes, by engineers, etc. (L.D.W.)

BARRACUDA. Pisces, Teleostei. Vicious marine fishes (**Pisces**) of several species, found in coastal waters of temperate and tropical seas. They are said to be a more probable source of danger to bathers than the sharks; since many of them attain a length of 6′ or more they are undoubtedly capable of inflicting severe injury.

The flesh is excellent and the fishes are caught both for sport and for the market.

The name barracuda is also applied to a New Zealand fish of the same order but of a different family. (A.W.L.)

BARRIER BEACH. A recently emerged coast (like the present Atlantic Coastal Plain) with shallow water extending for some distance from the shore will lend itself to the formation of barrier beaches. Waves tend to stir up the bottom materials of sand and gravel to be redistributed which gradually build up a low ridge parallel to the coast. Such barrier beaches are also known as offshore bars and the quiet body of shallow water between the bar and the mainland is called a lagoon. (E.S.C.S.)

BARYCENTRIC PARALLAX. Barycentric parallax is a term given to a slight oscillatory motion of the **earth.** The **center of gravity** of the earth-moon system revolves about the sun in an **orbit** that is usually referred to as the orbit of the earth. Both the earth and **moon** are revolving about this center of gravity of the system as it in turn revolves about the sun. At the time of **conjunction** of the moon with the sun the moon is inside of the orbit of the system about the sun and the center of the earth is outside. At opposition this condition is reversed and the center of the earth is on the inside. Hence, the center of the earth oscillates slightly back and forth across the orbit with a period of one **synodic** month. This slight oscillatory motion of the earth is known as barycentric parallax.

Accurate measurements of barycentric parallax provide a method for the determination of the relative masses of the earth and the moon. In accordance with the principles of mechanical equilibrium the distances of the center of gravity of the earth-moon system from the centers of mass of the two individual objects are inversely proportional to the masses of the objects. Hence, if we can determine the distance of this center of mass of the system from the centers of the earth and moon we can at once determine the relative masses of the two objects. Accurate measurements of barycentric parallax determine the position of the center of mass of the earth-moon system as 2880 miles from the center of the earth. Since this is about 1/82.5 of the distance of the moon from the earth, we find that the mass of the moon should be 1/81.5 the mass of the earth. (W.K.G.)

BARYE. The barye, or bar as now commonly written, is the c.g.s. absolute unit of pressure, equal to one dyne per sq. cm. It is of course a very small unit, one atmosphere (760 mm. of mercury) being equal to about 1,013,246 baryes. Hence the megabarye or megabar, i.e., 1,000,000 baryes, is often more convenient. Some confusion exists in the use of these terms, some authors using "barye" to designate 1,000,000 dynes per sq. cm. and "microbarye" as synonymous with the barye above defined. Still more unfortunate is the term "barie," defined as 750 mm. of mercury, and hence very nearly equal to 1,000,000 dynes per sq. cm., though fixed on an altogether different basis. Acoustic engineers commonly express sound pressures in bars. (L.D.W.)

BARYSPHERE. Lithosphere.

BARYTES. Barite.

BARYTOCALCITE. This mineral is a **carbonate of barium and calcium** which crystallizes in the **monoclinic system** but occurs massive as well. It has a perfect cleavage parallel to the prism and one, less perfect, parallel to the base; fracture, sub-conchoidal; brittle; hardness, 4; specific gravity, 3.64–3.66; luster, vitreous; color, white or gray or may be greenish or yellowish; transparent to translucent. Barytocalcite is found in Cumberland, England, associated with **barite** and **fluorite.** (E.S.C.S.)

BASAL CONGLOMERATE. A conglomerate that lies on, or occurs just above, a plane of erosion or **unconformity.** Such a conglomerate constitutes the first **sedimentary** stage in a normal cycle of sedimentation. (R.M.F.)

BASAL METABOLISM. Metabolism.

BASALT. A fine-grained to dense, sometimes **porphyritic,** intrusive or extrusive **igneous rock,** black or greenish-black in color, characterized by a preponderance of calcic **plagioclase feldspars** and **pyroxene** together with minor amounts of accessory minerals such as **olivine.** Glass may be present. Amygdaloidal structure is common in such cavities and beautifully crystallized species of **zeolites, quartz** or **calcite** are frequently found.

The lava flows of the Plateau of the Deccan in India, the Columbia Plateau of Washington and Oregon States, as well as the Triassic lavas of eastern North America are basalts. Perhaps the most famous basalt flow in the world is the Giants Causeway on the northern coast of Ireland, in which the vertical joints give the impression of having been artificially constructed. Pliny used the word basalt and it is said to have had an Ethiopian origin, meaning a black stone. (R.M.F.)

BASANITE. Tephrite.

BASE. See individual bases under each metal; also **Acids, Bases and Salts.**

BASE CIRCLE. Involute.

BASE LEVEL. The ultimate physiographic feature of the processes of **denudation** is the reduction of the land surface to sea level, because it is at this level that the processes of river **erosion** are completely checked. As sea level is the datum plane below which stream erosion is impossible this may be taken as the theoretical lower limit of stream erosion and the level to which all the land surfaces must be brought if no other forces intervene. Actually, however, base level seems to be a limit which, however closely approached, may not in reality ever be reached. Therefore a broader use of the term base level is frequently made, base level being the lowest level to which a given stream can cut. A stream flowing into a body of water at an elevation above the ultimate datum, sea level, is said to be at a temporary base level. In any case when a stream has cut its channel to such a degree that it has just enough velocity to carry its load without further erosion being possible, it is then said to be at grade. Local or temporary base levels of relatively small area may be developed without reference to sea level. In this sense the term base level is not entirely comparable to the term **peneplain.** (E.S.C.S.)

BASE LINE. Base line is a **surveying** term employed to describe an accurately measured horizontal distance which is obtained by the use of a graduated steel or invar tape (see **Chain**). The purpose of this measurement is to establish accurately the horizontal distance between two points called stations, from which to proceed with the instrument surveying. The base line should, if possible, be located where the terrain intervening between its ends is fairly level so that the measurements may be simply yet accurately made. The purpose for which a base line is laid out determines the degree of precision which is to be used in the measurements of this line. The base line, laid out along the bank of a river in order to determine the width of the river by instrument sights taken from each end to a fixed point on the other bank, would not need to be as accurate as that for first order **triangulation** of the character needed in Coast and Geodetic surveying. The latter requires the use of a special tape standardized under certain conditions and made of invar, which has a very low coefficient of temperature expansion. When used in base line measurements for first order work the tape must be supported at intervals so as to eliminate, as far as possible, the effect of sag. Spring balances are required to reproduce the tension under which the tape was standardized. Thermometers are employed to record the temperature so that correction may be made for the thermal changes.

Another meaning of base line is connected with the methods of public **land subdivision** used principally in the western part of the United States. The primary unit of subdivision is the township, which is subdivided into sections. These units are referred to a pair of principal axes which have their origin at the intersection of a true **meridian** called the principal meridian, and the true parallel of **latitude** called the base line. (F.T.M.)

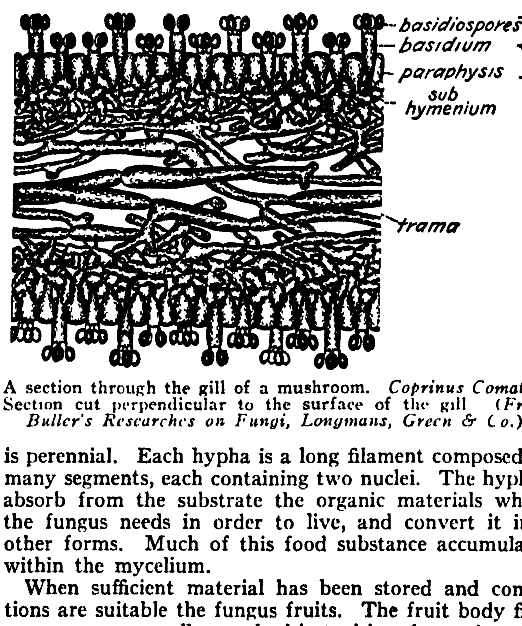
BASEMENT MEMBRANE. Epithelium.

BASIC ROCK. A term applied to **igneous rocks** whose content of silica is less than about 52%. It is not an exact term and is gradually going out of use. It may be convenient for field use. (E.S.C.S.)

BASIC SIZE. Interchangeable Manufacturing.

BASIDIOMYCETES. Nearly all the **fungi** commonly observed belong to this group, which includes toadstools, mushrooms, puff-balls, and many other forms. The characteristic feature which distinguishes them from other fungi is the basidium, typically a club-shaped structure bearing 4 **spores** at its apex. Members of this group are found wherever plant life can exist. The majority of them are **saprophytes,** living on dead wood and soil rich in humus; a few are parasites. The life-history of the common mushroom, one of the best known and most important, is fairly typical of the group.

The vegetative phase consists of a mycelium. This is a mass of slender much-branched threads, called hyphae, which grow throughout the substratum. The mycelium



A section through the gill of a mushroom. *Coprinus Comatus.* Section cut perpendicular to the surface of the gill (*From Buller's Researches on Fungi, Longmans, Green & Co.*)

is perennial. Each hypha is a long filament composed of many segments, each containing two nuclei. The hyphae absorb from the substrate the organic materials which the fungus needs in order to live, and convert it into other forms. Much of this food substance accumulates within the mycelium.

When sufficient material has been stored and conditions are suitable the fungus fruits. The fruit body first appears as a small round object rising from the substratum. At first a thin membrane completely envelops the fruit body. When the latter elongates, the membrane is broken, revealing the elongating stalk bearing at its tip an umbrella-shaped cap or pileus. Remnants of the broken membrane sometimes remain on the surface of the pileus or around its edge. Part of the membrane often remains at the base of the stalk, forming a cup-like volva. In some species of mushrooms the membrane is double. The inner portion, when broken, forms a ring, called the annulus, around the stalk. Both volva and annulus are found in many mushrooms; others have only one of them; in many no trace of either structure appears.

On the lower surface of the pileus there are numerous thin radiating plates called gills. The lateral surfaces of

the gills are formed by hyphal tips which grow perpendicular to the surface and form a compact layer called the hymenium. The hyphal tips composing the hymenium are the basidia, the reproductive structures which

Development of basidium and formation of spores in mushroom. 1, Septate mycelius with binucleate cells; 2, Young basidium containing two unrelated nuclei; 3, 4, Fusion of nuclei in basidium, 5, 7, Development of fournucleate condition in basidium, 8, Formation of basidiospores that receive the four nuclei. (*Redrawn from Harper*)

distinguish this group of fungi from all others. Each basidium is a cylindrical, binucleate (see **Nucleus**) body cut off from the tip of a hypha. The two nuclei fuse and immediately divide, usually twice, so that the basidium contains four haploid nuclei. From the outer end of the basidium four slender pegs called sterigmata develop. A small **spore** forms at the tip of each sterigma. Into each spore one of the nuclei of the basidium migrates. The spore is discharged from the sterigma and falls down between the gills and into the air. It is carried about by air currents and eventually falls to the ground. There the spore germinates, giving rise to a slender branching mycelium composed of uninucleate segments. This is the primary mycelium. Branches of two primary mycelia unite to form a secondary mycelium. The two nuclei present in each segment of a secondary mycelium have come from different spores. The manner in which they continue their identity during division is interesting. The two nuclei divide simultaneously. When division is about to occur a small bulge forms on the side of the hypha. One of the two nuclei enters this bulge, the other remains in the hypha. After division a cross wall forms, separating the two nuclei in the hypha. The protuberance containing the other nucleus continues to grow and forms an elbow-shaped structure, which joins the two cells of the hypha. It is called a clamp connection. One of the nuclei formed in this clamp returns to the original cell, the other passes through the clamp and into the other cell. By this means the two cells each receive a nucleus derived from one of the original nuclei Nuclear fusion occurs only in the basidium. So there is in the mushroom an **alternation of generations** differing from that in most plants. The haploid or gametophyte phase consists of the primary mycelia. Following this a prolonged binucleate or dicaryon phase exists. Only in the basidium does nuclear fusion occur and reduction immediately follows. So the diploid phase or sporophyte is represented only by the basidium. There are no sex organs in this group of plants. The differences between the edible mushroom and other basidiomycetes is mainly in the structure of the fruit body, the location of the hymenium and the nature of the basidia.

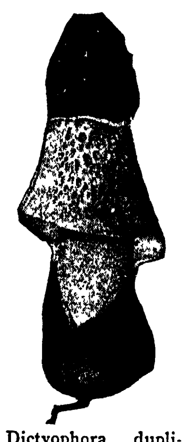
The nature of the hymenium is the basis for classifying basidiomycetes. The Hymenomycetes are those in which the hymenium is exposed; in the Gasteromycetes it is formed within the fruit body. The principal order of Hymenomycetes is the Agaricales or **agarics**, or the gill fungi. These are commonly described as mushrooms and toadstools. While popular conception gives to these two terms very exact meanings, actually the terms are confusing and of little value. A common distinction is that a mushroom is edible and a toadstool poisonous. The question is then how to distinguish a harmless fungus from one that is poisonous. To eat them is perhaps a certain but not a safe way. There are many definitions which aim to establish ways of distinguishing the noxious forms, based on the presence of volva and annulus, and other features. These do not always hold true. The only safe way is to learn to identify with certainty any fungus to be eaten and to reject all that are not known.

Another well-known order of basidiomycetes is the Polyporales; of these the polypores or Polyporaceae are best known. The distinguishing feature of these are the pits or tubes on the lower surface of the fruit body. The hymenium lines these pits. The fruit bodies of the polypores usually do not have a stalk and pileus, but form a layer spreading over the surface of rotting wood or grow out from the wood like a shelf. This shelf-like habit has given to these plants the name bracket-fungi. The fruit bodies of bracket-fungi live for many years and often show distinct growth layers. In some species these are a foot or more across and several inches thick.

The other large group of basidiomycetes is the Gasteromycetes, distinguished by having the hymenium lining irregular cavities in the fruit body. Until these are fully mature, the spore-bearing parts are completely enclosed by sterile tissue. There are many different kinds of Gasteromycetes One of the best known is the puff-balls, or Lycoperdiales. The outer wall or peridium of the puff-ball surrounds the gleba or spore-bearing tissues. When the spores are mature the peridium breaks. In some genera the wall breaks up into irregular fragments and leaves the spore-mass exposed; in others a pore is formed at the apex of the fruit body. The slightest pressure against the peridium will cause clouds of spores to puff from the pore. The number of spores formed in a single puff-ball is tremendous; 7,000,000 has been given as the number from a good-sized sporophore. Some of the puff-balls are the largest fungi known, reaching a diameter of a foot or more. If gathered before the spores are formed, most of the puff-balls are edible. None are poisonous.

Geasters or earth-stars develop very much as puff-balls do. But when they are mature the outer peridium splits into sectors which bend outward, revealing the spore-bearing part within. These fungi are frequently found growing on dry sandy soil.

Another group of Gasteromycetes includes the Bird's-nest fungi. The spore-bearing structures here are the "eggs," small oval bodies resting in the bottom of an open cup of sterile tissue. A last and curious group of Gasteromycetes is the stinkhorns, vile-smelling fungi whose spores are included in a mass of sticky stinking tissue, formed by the disintegrated glebal substance. This attracts carrion flies and other insects, which carry the spores about.



Dictyophora duplicata, Stinkhorn, a fleshy Basidiomycete.

Other important families of basidiomycetes are the **Rusts** and the **Smuts.**

There are several theories as to the origin of the basidiomycetes. Some maintain that they have evolved directly from certain primitive **flagellates.** Others derive them from the red **algae.** Many consider them to have descended from the **ascomycetes.** Adherents to this theory observe the dicaryon phase of the ascogenous hypha of the ascomycetes and note that if this phase were prolonged for some time it would be very similar to the secondary mycelium of the basidiomycete. They also note that the asexual reproduction by conidia occurs in the basidiomycetes very much as it does in the ascomycetes.

The basidiomycetes include many important plants. Many are much sought as food. A few, and especially the field mushroom, *Agaricus campestris,* are extensively

cultivated. This cultivation is commonly carried on in caves or cellars, where the requisite moisture conditions may be maintained and where sudden fluctuations in temperature are not so apt to occur. The mushrooms are grown in beds. A mushroom bed is composed of a mixture of well-rotted manure, straw and other vegetable matter and earth. This mixture is allowed to stand for some time until heating has ceased and the temperature is constant. Then bits of mushroom spawn are buried in the mass. Mushroom spawn is a dense mass of healthy mycelium growing in a suitable substrate. The spawn grows rapidly and penetrates all parts of the bed. After about three weeks, fruiting begins, the young sporophores pushing up from the surface of the bed. They are gathered in the early stages of their development and kept in cool airy rooms until marketed.

Agaricus campestris. The first figure shows the cultivated variety; the second, the wild form (*From Farlow's Icones Farlow Herbarium, Harvard University.*)

Many basidiomycetes are serious disease-producing plants, attacking trees particularly. Often their presence is unnoticed until too late; the mycelium has permeated the tissues of the host. Other basidiomycetes attack dead plants, reducing them to simpler forms. These are the basidiomycetes which cause decay. They are saprophytes. (R.M.W., B.S.M.)

BASILAR MEMBRANE. A membranous partition in the auditory chamber (cochlea) of the inner **ear** forming the floor of the cochlear duct. Upon it lies the organ of Corti, which contains the sensory cells for hearing. The basilar membrane increases in width as it passes from the base of the cochlea towards the apex, thus influencing the character of the vibrations with which the basilar membrane responds to sounds of different frequency. (A.W.L.)

BASILAR PLATE. A plate derived from the ventral wall of the first body segment in millipedes (**Diplopoda**) which forms the most posterior component of the mouth parts. (A.W.L.)

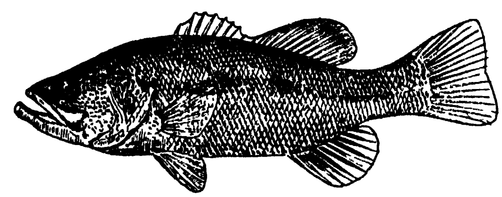
BASILISK. Reptilia, Sauria. *Basiliscus.* A large tropical American **lizard** with crests on the back and tail which resemble the fins of fishes. Four species are known. (A.W.L.)

BASIN. In structural geology, a special type of folded structure in which the strata **dip** in toward a central point from all directions. As exposed at the surface the ground plan of a basin may be roughly circular or elliptical. Type locality, the Paris Basin, France. (R.M.F.)

BASIPODITE. **Biramous Appendage.**

BASOMMATOPHORA. An order of fresh-water **snails** with eyes located at the bases of the **tentacles.** (A.W.L.)

BASS. Pisces, Teleostei. A term so loosely applied that no specific definition can be given. The small-mouthed and large-mouthed black bass, Kentucky bass, and warmouth bass are highly valued North American fresh water game and pan fishes. The white bass and yellow bass, also found in fresh water in North America, are members of another family which includes mostly marine species known as sea bass. These are also valuable for food and some species are excellent game fishes. Among the marine species the striped bass is important as a game fish on the Atlantic coast and the black sea-bass or jewfish of the Pacific coast is among the largest of marine game fishes, attaining a weight of 500 lbs. or more. (A.W.L.)



Large mouth black bass. (*Slingerland-Comstock Publishing Co.*)

BAST. As commonly used, the term bast is synonymous with **phloem.** (R.M.W.)

BAST FIBERS. In the **phloem, pericycle,** or cortex of many plants there occur long slender thick-walled cells with tapering ends. These cells, often occurring in groups of considerable size, are often called bast fibers. They give to the stem of the plant considerable strength. Many bast fibers are useful to man, especially in the manufacture of cloth and cordage. Linen is made from the pericyclic fibers of **flax,** while **hemp** and remie are coarser pericyclic **fibers** used in making coarse sacking and cordage. The phloem fibers of **jute** are also used for making rope and burlap, as well as the strong webbing used in upholstering furniture. Plant anatomists call them phloem fibers, pericyclic fibers, or cortical fibers. (R.M.W.)

BAT. Mammalia, Chiroptera. A flying **mammal** whose wings are formed of folds of skin, the patagia, stretching between greatly elongated digits of the fore limbs, the sides of the body and hind limbs, and thence to the tail. Since the wings are living tissue they form extensive radiating surfaces, a fact correlated with the much greater development of the group in warmer regions. Most species found in the temperate zones hibernate, although migration has been reported, and few species invade more northern limits of these zones.

It has recently been shown that the amazing ability of bats to avoid obstacles while flying rapidly in the dark is due to the reflection of sound waves from these objects as the animal approaches them. The bat emits a constant series of sounds so high-pitched that the human ear does not detect them, hence the use of suitable apparatus to bring them within range of human hearing is necessary to demonstrate their occurrence. The bat's ears are highly specialized to perceive these sounds and to determine by the elapsed time the direction of objects from which they are reflected and the distance of these objects.

The habits of bats vary greatly. The flying foxes or fruit bats of the Old World are fruit-eating species exclusively, the horseshoe and leaf-nosed bats are insectivorous, and some species of vampire and false vampire bats are blood-suckers. Among the bats with distinctive names are the **barbastelle,** pipistrelle, noctule and serotine, all found in Europe and other parts of the Old World. (A.W.L.)

BAT TICK. Insecta, Diptera. Highly specialized **flies** which live as **ectoparasites** on bats. Like other parasitic flies, their habits are accompanied by some structural resemblance to the true ticks, hence the inaccuracy of the common name. The bat ticks belong to two families, Streblidae and Nycteribiidae. All species of the latter are wingless. (A.W.L.)

BATAGUR. Reptilia, Chelonia. Large fresh-water **tortoises** of several genera found in India and the Malayan region. (A.W.L.)

BATHOLITH. Batholith, by some writers spelled bathylith, is derived from the Greek meaning deep, and stone. It is a very large intrusive **igneous** mass with steeply inclined contacts, enlarging downward to undetermined depths. Typical batholithic rocks have a relatively coarse and even texture, such as **granites** and **diorites.** Batholiths occur as the roots or cores of folded and faulted mountain ranges and are therefore closely associated with mountain-building, although probably not the cause of the deformation but rather consequent to it. The mode of emplacement of such large cross-cutting and relatively uniform igneous rock bodies has not yet been definitely determined. The term was proposed by Zuess in 1888. (R.M.F.)

BATHYSPHERE. A closed and air-tight chamber arranged to contain observers, and to be lowered at the end of a cable to great depths of water, is a bathysphere. It is principally used for scientific study of animal life and other conditions in the depths of the ocean. The bathysphere is spherical in shape. It has a small observation window and a telephone, the lead of which is unwound along with the supporting cable. The observer keeps in communication with the mother vessel and possibly dictates notes by means of his telephone. Suffocation is forestalled by the slow release of compressed oxygen from tanks. Depths of 3028′ have been reached by the bathysphere, and this, of course, is far beyond the maximum depth achieved by divers or submarines. (F.T.M.)

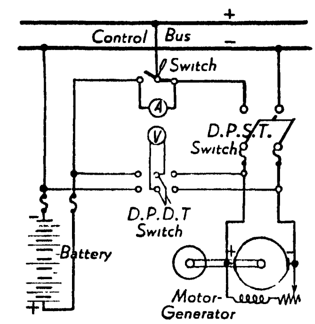
BATONETTE. Cell.

BATRACHIA. The frogs and toads.

BATTERY. The term battery refers to any group of duplicate units which are contributing individually to a common effect. A common usage of battery is in reference to a group of cannon forming, with the personnel, a military offensive unit. The word is also frequently applied to engineering usage, such as battery of boilers, which consists of a number of individual boilers on a common header supplying steam to a common service, or a battery of mixers, etc.

But by far the most common usage of the word is in reference to a collection of chemical cells for the production or storage of electrical energy. As such, the battery may be of the primary type, of which the individual unit is the primary **cell,** or it may be the ordinary **storage battery,** which is, strictly speaking, an electrical accumulator. The lead and sulfuric acid storage battery is the one most frequently found. A single cell of this type of battery has an e.m.f. of between 2 and 2½ volts when fully charged, and an ampere-hour capacity which is dependent upon the exposed area of the plates to which the electrolyte has access, as well as upon the quality of construction.

The electric system of the automobile is based upon the 3-cell, 6-volt storage battery. Farm lighting plants are frequently 32-volt, and require 16 cells. A 60-cell battery is standard for 110-volt service. To obtain these voltages, the cells must be connected in series. When a storage battery is used, the accumulated energy is withdrawn through the conversion of chemical energy into electrical energy. Without some means of recharging, the battery will become completely dis-



Battery and motor-generator parallel on control bus.

charged, and cease to deliver current. Automotive batteries are charged from a **generator** which is driven by the engine. Farm lighting batteries are recharged periodically by a special stationary engine-driven generator. Larger batteries, such, for instance, as those on 110-volt control buses, are usually kept charged by a motor-generator set or **trickle charger** which converts some available source of a.c. into d.c. The accompanying figure shows a connection frequently employed where the direct current bus can be energized either by a motor generator or a battery, and the same motor generator used to recharge the battery. (See **Electric Cell.**) (F.T.M., L.R.Q.)

BAUMÉ SCALE. A special **hydrometer** scale in industrial use, really two scales, one for liquids *lighter* than water and another for liquids *heavier* than water. The former is used in the petroleum industry and the latter in the acid and heavy chemical industry.

For Liquids Lighter than Water	Degrees Baumé	For Liquids Heavier than Water
	0	1.000
1.000	10	1.074
0.933	20	1.160
0.875	30	1.261
0.823	40	1.381
0.778	50	1.526
0.737	60	1.706
0.700	70	1.933
0.669	80	2.231

(R.K.S.)

BAUXITE. The term applied, by Dufrenoy in 1847, to the amorphous mineral aluminum oxide dihydrate ($Al_2O_3 \cdot 2H_2O$), an important ore of **aluminum.** The term is also applied to aluminous **laterites** which contain commercial amounts of aluminum hydroxide. (See **Gibbsite.**) (R.M.F.)

BAY OIL. Volatile Oils.

BAYBERRY. *Myrica cerifera.* Myricaceae. This is a shrub which is found in marshy places in the United States. The simple leaves are very fragrant, especially when crushed, and are sometimes used in cooking. The fruit, a blackish drupe (see **Fruit**), is thickly coated with a mealy crust of wax. To obtain this wax, the fruits are boiled in water, causing the wax to melt and float to the top. The wax is pale green and very fragrant. It is used in making candles and also in scented soaps. The wax from this plant, and from other species of *Myrica,* has been used medicinally.

Sweet bay is the true laurel, *Laurus nobilis,* a small

tree found in the Mediterranean region. The leaves are very fragrant and are used as a condiment. From the berries a fragrant oil is obtained which is used medicinally. (R.M.W.)

BAYONET CHUCK. Chuck.

BAYES' THEOREM. Let $c_1, c_2, c_3 \cdots c_s$ be some s mutually exclusive random events such that one of them must happen and let $P(c_i)$ be the **probability** of c_i. These events we shall describe as causes. Let E be some event which can be directly observed and let $P(E \mid c_i)$ be the probability that E will occur on the assumption that c_i has already happened. Let $P(c_i \mid E)$ be the probability of c_i after E has occurred. The probabilities $P(c_i)$ are called "a priori" probabilities, i.e., probabilities not at all dependent on the event E, where $P(c_i \mid E)$ are called "a posteriori" probabilities since these depend on the event E having occurred. Bayes' theorem states

$$P(c_i \mid E) = \frac{P(c_i)\cdot P(E \mid c_i)}{\sum_{j=1}^{s} P(c_j)P(E \mid c_j)}.$$

The theorem states exactly how the probability of a certain "cause" changes as different events actually occur. The theorem was published posthumously in 1764. When all conditions of the theorem are fulfilled there is no objection to Bayes' theorem. The difficulties in applying the theorem depend upon the fact that $P(c_i)$, the "a priori" probabilities, are not known and are assumed often to be equal in the absence of other knowledge. Bayes' theorem has been made the foundation of the theory of testing statistical hypotheses by some statisticians. However, it has been found to be unscientific, to give rise to various inconsistencies, and to be unnecessary. The modern theory of testing hypotheses makes no use of it. (L.A.A.)

BAYOU (Oxbow). A stagnant or abandoned course of a meandering river. Also a general term for a stagnant inlet or outlet of a lake or bay. (R.M.F.)

B BOARD. Telephony.

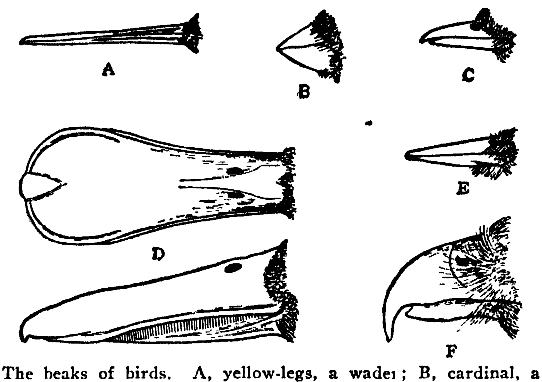
BDELLOIDEA. An order of rotifers, named for their fancied resemblance to leeches. (A.W.L.)

BDELLONEMERTEA. An order of **nemertine** worms of broad, flat form, named from their superficial resemblance to leeches. They live in the branchial chamber of **mollusks.** (A.W.L.)

BEAK. 1. A pointed protuberance. 2. The snout or rostrum of an animal, such as the beaked whale. 3. The horn-covered jaws of turtles and birds. The beak of birds is also called the bill. 4. The jaws of **cephalopod** mollusks.

Beaks of birds show a wide range of specialization for various uses, especially related to different types of food. Slender and elongate beaks are found in many wading species which must reach below the water for food and in the **hummingbirds** which visit deep-throated flowers. The broad beak of the **duck** has sieve-like structures at the sides and serves effectively to collect and strain out small particles from the water. The hooked beaks of birds of prey, small and slender beaks of insectivorous birds, and thick, strong beaks of seed-eating species are other examples.

The cephalopod mollusks, including the **squids, octopus** and related species, have two sharp jaws associated with the mouth which work together and resemble the beak of a bird. (A.W.L.)



The beaks of birds. A, yellow-legs, a wader; B, cardinal, a seed-eater; C, flycatcher, an insect eater; D, the shoveler duck, dorsal surface above and side view showing the lateral sieve below; E, a woodpecker's chisel-tipped beak, F, hawk, a bird of prey.

BEAKED FISH. Pisces, Teleostei. A member of a group of African fishes (**Pisces**), some of which have the snout sharply elongated. Beaked members of other groups also occur, including the beaked salmon, which ranges from Japan to Australia This fish is not a true salmon but constitutes a separate family. (A.W.L.)

BEAM. A beam is a straight or initially curved member which supports **bending loads** without the aid of **arch** action. (See **Cantilever Beam, Continuous Beam, Curved Beam, Fixed Beam, Indeterminate Structure, Simple Beam.**)

The term is also used to designate certain rolled steel sections such as the **I-beam** and the **wide flange beam** which may be used as beams or **columns.** (C.W.C.)

BEAM BRIDGE. Bridge.

BEAM POWER TUBE. This is a type of tetrode used for power amplification (see **Amplifiers**) in which the **electrons** passing from the **cathode** to the **anode** are concentrated into a beam which causes them to form a space charge near the anode and turn back any secondary electrons which are emitted from the anode. In this respect the tube behaves like a pentode (see **Tubes**), but, since it does not actually have the suppressor grid in the way of the electrons, it has a somewhat more desirable operating characteristic. (L.R.Q.)

BEAN. The fruits of many different plants and in many cases the plants themselves are called beans. Nearly all of them are members of the **Leguminosae.** In Europe and America, beans are principally plants of the genus *Phaseolus,* with *Phaseolus vulgaris,* the common Garden Bean, a most important species, with many varieties in cultivation. This plant is a tender annual, probably originally native in South America, and grows either as a low bush or as a twiner. Many of the varieties grown have been selected to yield a thick, rather fleshy pod with small seeds; these are string or snap beans. In some varieties chlorophyll (see **Pigments in Plants**) is either entirely or largely lacking in the pods, giving the Wax or butter bean. Many other varieties are grown primarily for the dried seeds, which have a very high food value and keep exceedingly well if dried and protected from insects. Common varieties used as dry beans are Pea, Yellow Eye and Red Kidney beans. Shell beans are those in which the nearly mature but green seed is eaten.

Related to the Garden Bean is *Phaseolus multiflorus,* the Scarlet Runner Bean, which is often grown as an ornamental plant because of its showy scarlet flowers. Another species, widely grown in warmer climates, is

Phaseolus lunatus, the Lima Bean, another plant from South America. The large flat pods of this plant contain a few large flat seeds. Varieties have been developed which can successfully mature in regions having a short growing season.

In Europe a common bean is the Broad Bean, also called Windsor or Horse Bean, *Vicia faba.* Its seeds are rich in nitrogenous compounds and rather hard to digest. These seeds are extensively used for horse food, as well as for human consumption.

In the Orient, the bean crop is almost entirely *Glycine Max,* the Soy Bean. The plant is an erect bushy annual with trifoliate leaves and bears fruit (pods) in great abundance. Tremendous quantities are grown in Manchuria. The plant has been introduced into the United States, where it is becoming increasingly popular, for several reasons. One is the fact that it will grow well on poor soils and, being a legume, will build up the fertility of the soil, because of its associated nitrogen-fixing **bacteria.** It is also an important forage crop. The seeds are rich in oil and have received much attention from chemists, with the result that large quantities are now used in the preparation of enamels, linoleum, inks, paints, soaps, etc. The cake remaining after the oil is pressed out is used as a stock food. Unquestionably, soy bean culture will increase in the United States in the future.

In Africa, species of *Dolichos* are used as food.

All the plants so far treated are legumes having "bean-" like fruit. But in the Vanilla bean one deals with an entirely different plant. Vanilla beans are the fruits of a climbing **orchid** growing wild in Central America and Mexico. Since prehistoric times these fruits have been used to flavor chocolate. At the present time (and with some difficulty) the plant is cultivated in several tropical countries, both in America and in the Orient. Like many other orchids, the flowers are pollinated only by certain specially adapted bees and perhaps the **Hummingbirds.** When introduced into regions where the necessary insects are lacking, **pollination** must be done by hand. The fruits, or pods, are slender elongate structures containing innumerable minute seeds. These seeds are germinated with difficulty, so new plants are usually obtained by cuttings of the old stem. Three years are required before the rooted cuttings will begin to bear fruit. In preparing the pods for market, they are first gathered and partially dried. After this they are stored in tight boxes during the night. This process is repeated daily throughout the period of "sweating." As a result of this treatment, the pods become deep chocolate brown, somewhat wrinkled objects, having a rich aromatic odor. The cured pods are packed in tight containers and shipped to the manufacturers of the extract. Vanilla is used mainly as a flavoring.

Many other plants contain vanillin, or similar substances, and so are often used in the manufacture of artificial vanilla. Among these are the seeds of a tropical South American plant, Coumarouna, which yield a product coumarin, used in **perfumery.** The seeds from which this coumarin is obtained are called Tonka Beans. (R.M.W.)

BEAN WEEVIL. Insecta, Coleoptera. The common bean weevil is a small **beetle,** *Mylabris obtectus,* which attacks growing beans and cowpeas in the pod. Methods of control are the same as for the **pea weevil.** The four-spotted bean weevil is a related species which attacks beans and peas both in the field and in storage. Control as above. (A.W.L.)

BEAR. Mammalia, Carnivora. Large, heavily built animals with rudimentary tail and plantigrade feet. In North America the polar bear, *Thallasarctus maritimus,* black bear, *Ursus americanus,* grizzly, *U. horribilis,* and Kadiak bear are recognized species and several less familiar names apply to species of brown bears of Alaska. The term brown bear itself does not designate a single species. Numerous varieties of the black and grizzly bears also occur.

Bears are found in every continent except Australia, although Africa and South America have only one species each. The African species, known as Crowther's bear, is found in the Atlas mountains and is related to the European brown bear. The South American spectacled bear, named from the light-colored rings around the eyes, lives in the Peruvian Andes. Among the more striking bears of Eurasia are the Himalayan bear, a black bear of moderate size with a white chevron on its breast, and the peculiar sloth-bear, *Melursus labiatus,* of India which has unusually large curved claws.

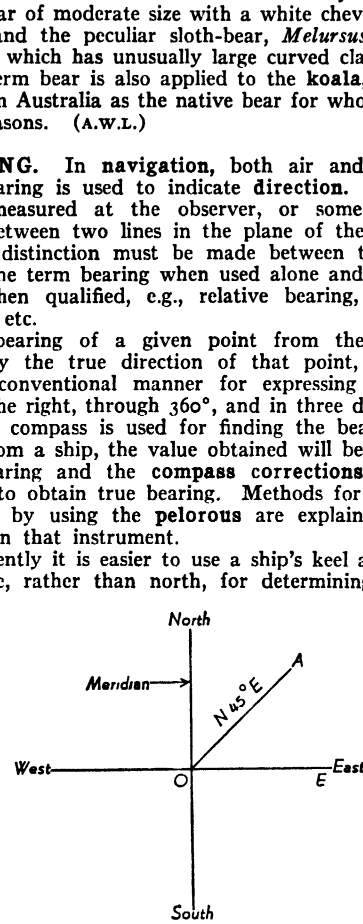
The term bear is also applied to the **koala,** which is known in Australia as the native bear for wholly superficial reasons. (A.W.L.)

BEARING. In **navigation,** both air and sea, the term bearing is used to indicate **direction.** It is the angle, measured at the observer, or some specified point, between two lines in the plane of the **horizon.** Careful distinction must be made between the meaning of the term bearing when used alone and the same term when qualified, e.g., relative bearing, **compass** bearing, etc.

The bearing of a given point from the observer is simply the true direction of that point, expressed in the conventional manner for expressing direction, i.e., to the right, through 360°, and in three digits.

If the compass is used for finding the bearing of a point from a ship, the value obtained will be the compass bearing and the **compass corrections** must be applied to obtain true bearing. Methods for obtaining bearings by using the **pelorous** are explained in the article on that instrument.

Frequently it is easier to use a ship's keel as a reference line, rather than north, for determining bearing.



Bearing (Directional)

In this case relative bearing is obtained. This is defined as the angle between the keel of the ship and a line in the plane of the horizon to the object. This angle is measured from the forward end of the keel, to the right through 360°, and expressed in three digits. To find the bearing of the object when the relative bearing is known, the **heading** must be added to the relative bearing. For example, a ship is heading 326° and the relative bearing of a **buoy** is 124°. The bearing of the buoy is $326° + 124° = 450°$, or 090°, and the buoy is due east of the ship. **Radio bearings,** taken with a radio direction-finder, are always given as relative bearings from the ship.

Lookouts on ships, gunners on planes, and other observers of this general type, may not have a pelorous available to determine bearings of a sighted object. Various approximate methods are in use for expressing relative bearings, depending upon the particular service. Lookouts on ships at sea frequently report relative bearings in terms of compass points. For example: an object sighted one point (11°.25) to the right of the bow would be reported as "one point off

the starboard bow." An object with relative bearing 315° would be reported as "broad on the port bow," etc. In the air-services, clock numbers are sometimes used for reporting relative bearings, e.g., an object with relative bearing about 300° would be reported as "at ten o'clock." Complete descriptions of the various approximate methods used in the various services may be found in manuals of seamanship, regulations of the U. S. Army Air Corps, etc.

In surveying, bearing is usually expressed in terms of the acute angle measured either from north or south to the east or west. For example: a bearing of 135° would be expressed as S 45° E (south 45° east); a bearing of 290° as N 70° W, etc.

The latitude of a line is its orthographic projection on the meridian; the departure is its orthographic projection on a line perpendicular to the meridian.

$$\text{Latitude} = \text{Length} \times \text{cosine of bearing.}$$
$$\text{Departure} = \text{Length} \times \text{sine of bearing.}$$

Latitudes are positive for north bearings and negative for south bearings. Departures are positive for east bearings and negative for west bearings. In a theoretically closed **traverse** the algebraic sum of both the latitudes and the departures must be zero.

The bearing of any line such as *OA* referred to a meridian through *O* is a forward bearing; if referred to a meridian through *A* it is a back bearing or reverse bearing. Forward and back bearings differ by 180°.

Bearing is a mechanical term used to denote that part of a machine which bears the friction occasioned when parts are in contact and have relative motion. Bearings are to be found in a variety of forms, for example, lubricated and unlubricated, rotating and sliding, weight-carrying and thrust-carrying, etc. See also **Anti-friction Bearings, Bearing Friction,** and **Bearings.**

Bearing is a structural term denoting that part of a structure which transmits the loads to the supports. Rolled steel plates, known as bedplates, are used for bearings for roof trusses, short plate girder bridges and wall bearing beams. Cast steel pedestals have been used in place of bedplates. Bridges are usually supported on hinged pedestals called shoes which are made of cast steel or from rolled steel shapes riveted or welded together. The hinge consists of a heat-treated steel pin through which the loads on the **truss** are transferred to the shoe. A fixed shoe is one which is firmly connected to the support. Shoes which allow a certain degree of movement in one direction are expansion shoes. In one type of expansion shoes rollers are used to provide the necessary means for movement and another type employs the principle of the rocker. Simply supported bridges require fixed shoes at one end and expansion shoes at the other end to take care of the movement due to temperature changes.

The allowable pressure which may be exerted on a material is often called its bearing power. The force exerted by a plate on a rivet or pin is known as a bearing pressure. A compressive **stress** is frequently referred to as a bearing stress. (C.W.C., W.K.G.)

BEARING METALS. A great variety of alloys can be used as bearing metals. Probably the best known is **babbitt,** a tin-base alloy containing antimony and copper. Other so-called white metal bearing alloys have either lead, cadmium, or zinc as the principal element. Aluminum alloys are infrequently used for bearing purposes, although aluminum pistons cannot be discounted as bearing materials. The bearing plates for bridges and structures described under **bearing** are often a high tin bronze. Bronzes and leaded bronzes have many other applications as bearing surfaces in machines, particularly where the unit pressures are greater than can be withstood by babbitt and similar materials. (See **Brass and Bronze.**)

Internal combustion engine bearings range from **babbitt,** which is now used as a very thin coating on a steel backing, to pure silver. Other important materials are leaded copper, the cadmium base alloys, and certain composite bearings consisting of a tin or lead base alloy bonded to steel by means of a bronze intermediate layer.

For the most exacting applications such as main bearings in aircraft engines, silver bearings are used. A thin film of indium is often applied to silver and other bearing surfaces to provide self-lubrication during the run-in period.

Cast iron is a very important bearing material. In addition to engine blocks, pistons, and rings, all of which require good bearing properties, cast-iron plain bearings perform satisfactorily with steel shafts where service conditions are not too exacting.

In the field of **anti-friction bearings,** hardened steel balls, rollers, and races form the bearing surfaces. Where even greater hardness, wear resistance, or precision is required, as in instruments and watches, jeweled bearings are used.

The requirements of a good bearing material obviously vary with the application but may include any of the following: wear resistance, compressive strength to resist extrusion or displacement, plasticity to accommodate slight misalignment or irregularities, shock resistance, fatigue resistance, low frictional characteristics to prevent galling or seizure, retention of strength and wear resistance at the temperatures developed in operation, high thermal conductivity to reduce operating temperatures, good bonding characteristics with the liner or container, and corrosion resistance under operating conditions. (R.H.H.)

BEARING MODULUS. The relationship Zn/p between the absolute viscosity Z of an oil, the bearing speed n in rpm, and the unit pressure p on the bearing, in lbs. per sq. in. of projected area. (H.C.H.)

BEARING STRESS. **Stress.**

BEARINGS. Bearings are employed to support, guide, and restrain moving elements. They may be classified as bearings for rotating and oscillating elements, and as bearings for reciprocating elements. Bearings for rotating or oscillating elements may be further classified as journal bearings and as anti-friction bearings.

A *journal bearing* is composed of two essential parts, the journal, which is the inner cylindrical or conical part and which usually rotates, and the bearing or surrounding shell, which may be stationary, as in the case of lineshaft bearings, or moving, as in a connecting rod bearing.

The simplest form of journal bearing embodies a shaft rotating in a hole in a frame or bracket. If any wear occurs in the bearing, it is necessary to replace the bracket or frame. For this reason, bearing holes are generally supplied with sleeves or bushings so that a comparatively inexpensive replacement is possible. The contact surfaces are lubricated through oil holes in the bushing.

Fig. 1 shows a split pillow block for transmission shafting, which has a babbitt-lined bearing surface.

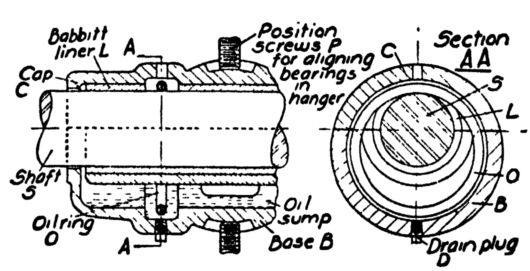


Fig. 1. Split pillow block.

The babbitt metal is cast into the cap and base of the bearing, and is locked in place by recesses or anchors in these members. This bearing is lubricated by a drop-feed oil cup or a grease cup which is screwed into the threaded hole in the cap. Split bearings are more expensive than solid or plain bearings but make it easier to remove and replace the shaft. Pillow blocks are usually stocked by manufacturers in sizes to fit standard transmission shafting.

Fig. 2 shows a split *ring-oiled bearing* for overhead transmission shafting. The entire bearing is supported by two positioning screws *P* in the hanger of Fig. 3. The hangers are made of cast iron or pressed steel and are attached to wooden ceiling joists by through bolts as illustrated, or by lag screws or hanger bolts. Hangers may also be attached to steel ceiling girders by steel girder clamps and bolts.

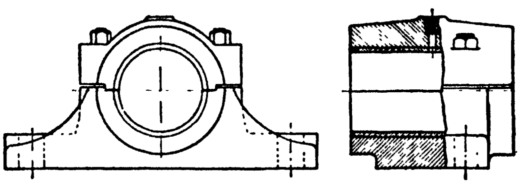

Fig. 2. Split ring-oiled bearing for overhead transmission shafting

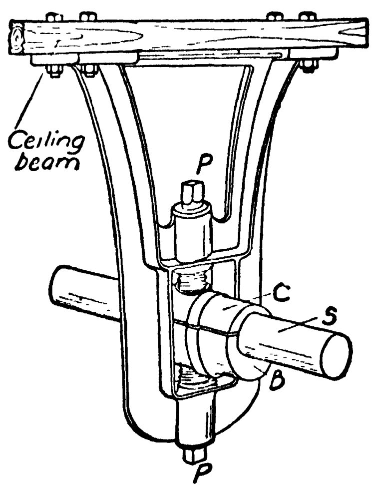

Fig. 3

Thrust bearings are used for axial restraint, and are very important where heavy axial loads may prevail, as in vertical hydraulic turbo-generator sets, worm gearing, etc. In such instances, a collar on the rotating shaft rests on a series of freely pivoting segments attached to the stationary bearing. The rotation of the collar induces a wedge-shaped oil film between its lower surface and the top of the segments to provide thick-film lubrication. For light thrust loads, one or more thrust washers, restrained by separate collars or integral shoulders on the shaft, are satisfactory. *Pivot bearings* are used in instruments and light mechanisms; the shaft or spindle has either a ball or spherical end or a 60° conical end, which rotates in a mating conical hole. The resulting bearing carries both radial and thrust loads. (See **Kingsbury Thrust Bearing.**)

Fig. 4 illustrates several types of bearings for reciprocating slides. Both dovetail and rectangular slides are generally made with some form of gib or adjustable strip, so that the slide may be properly fitted and also to enable the slide to be clamped in the guide if desirable. The taper gib, which is adjusted by a double collar screw, is by far the most effective gib but the guide must be planed with one tapered side. The flat gib is the least expensive but does not give as good contact with the slide as the other forms. The V-flat narrow slide is employed on lathes and in installations where the length of the slide is less than the total width of the member.

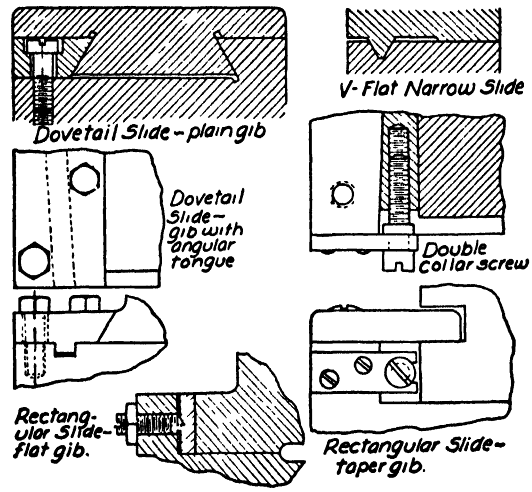

Fig. 4. Types of bearings.

Ball and roller bearings are known as *anti-friction bearings*, and have certain advantages over journal bearings. The actual bearing friction is less than in sliding bearings, and, as it is principally rolling friction, there is little danger of abrasion in machines that are frequently started and stopped under load. Rolling bearings will maintain relatively accurate alignment of parts over long periods of time, can carry heavy momentary overloads without failure, and are very easily lubricated.

Fig 5 illustrates a single-row radial ball bearing and housing. The bearing has four elements: the outer race which fits in the housing; the inner race which fits on the shaft; and the cage or retainer which separates the balls and keeps them properly spaced about the periphery of the unit. Theoretically there is no reason why the balls could not roll on the shaft and in the housing, but the races are employed to maintain the proper fit and to provide satisfactory surfaces of the proper degree of hardness for the balls to roll on. In the figure, the bearing is resting against a shoulder on the shaft, and is held in position by a lock nut which may be locked at any twenty-fourth of a turn by the washer.

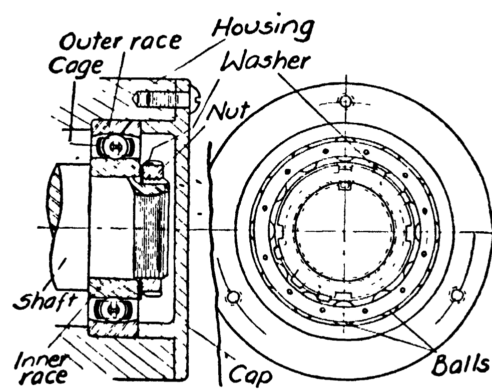

Fig. 5. Single-row radial ball bearing and housing.

Ball bearings are generally supplied with bores, widths, and outer diameters in millimeters since the bearings were originally used in quantity in Germany, but bearings in standard inch sizes are also available at the present time. Radial ball bearings are made in three series—light, medium and heavy—and are numbered as follows: 205, 305 and 405, respectively. The bore, in millimeters, between sizes 204 and 213 in the light series, for example, is five times the last figure in the bearing number. Bearings 205, 305, and 405, for example, all have the same bore (25 mm.) but the medium and heavy series bearings, which are used for greater loads than the 205 bearings, have larger outer diameters and greater widths.

Double-row bearings have approximately twice the load-carrying capacity of single-row bearings of the same bore, and occupy less space than two single-row bearings.

Angular-contact ball bearings are designed to take a combination of radial and thrust loads, and should be used in pairs unless the load is pure thrust. This type of bearing is adapted to preloading, which consists of placing it under an initial load which is independent of the working load. Preloading tends to reduce the axial deflection under working loads, thus maintaining accurate alignment of the shaft or spindle elements. Self-aligning bearings are double-row bearings with a spherical surface on the inside of the outer race. This construction allows some deflection in the shaft without causing the bearings to bind.

Roller bearings have a greater load-carrying capacity but develop more friction than ball bearings of similar size. Cylindrical roller bearings are made in three series, similar to ball bearings, and have rollers whose diameters are approximately equal to their lengths. Needle bearings have cylindrical rollers of small diameter and considerable length, and operate without a cage or retainer. They occupy very little diametral space in relation to their load-carrying capacity, and are therefore coming into extensive use in gear mountings, and as piston pin bearings in large internal combustion engines.

Hyatt roller bearings have hollow cylindrical rollers that are made by winding strip steel into helical form. The hollow construction permits greater deflection under load. The bearing is made with inner and outer races but has been successfully applied to transmission shafting where the rollers bear directly on the surface of the shaft. Tapered roller bearings, Fig. 6, are extensively used for machine tool and automotive appli-

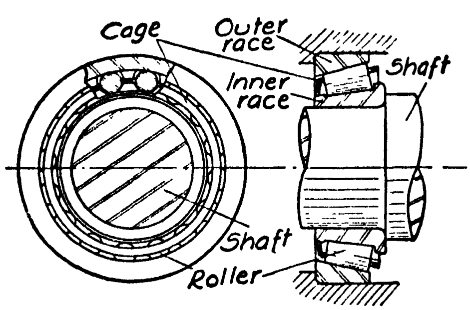

Fig. 6. Tapered roller bearings.

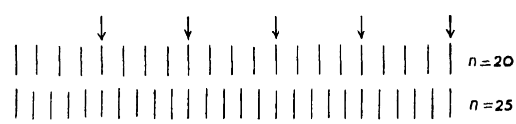
cations, and are capable of taking heavy unidirectional thrust loads in addition to large radial loads. The bearings are used in pairs for two-directional thrust. In some recently developed machine tools, rectilinear slides supported by two "chains" of bearing balls are used to provide practically frictionless table movement. Ball ways have been applied to cutter grinding machinery and radial drill presses, and will probably find further use in future developments. (H.C.H.)

BEAT FREQUENCY. When two signals of different frequencies are applied to a non-linear circuit, they will combine, or beat together, and give, among other components, one which has a frequency equal to the difference of the two applied frequencies. This difference frequency is known as the beat frequency. There are numerous applications of this effect, but two of the major ones in the communications fields are in the reception of **continuous wave signals** and in frequency shifting as in the **superheterodyne** receiver. Since continuous wave signals have no audio superimposed on them, they cannot be made audible by ordinary detection methods. However, if the incoming signal is beat with a local signal, differing by an audible amount, the result is an audible beat frequency. Frequency shifting by use of beat frequencies is applied in the superheterodyne, in **carrier** telephony, frequency **modulation,** and numerous other circuits. In most of these applications use is made of the fact that if one of the signals is modulated, the beat frequency signal will have the same **modulation.** (L.R.Q.)

BEAT FREQUENCY OSCILLATOR. This is any conventional **oscillator** whose function is to produce the signal to mix with a signal whose frequency is to be shifted. Thus in a **continuous wave** receiver, it is the oscillator causing an audible beat, in the **superheterodyne** it is the oscillator causing the intermediate frequency beat. (See **Beat Frequency.**) (L.R.Q.)

BEATS. A series of alternate maxima and minima in **vibration** amplitude, produced by the **interference** of two **wave** trains of different frequency. A familiar



Five coincidences in unit time between wave trains of frequencies 20 and 25.

example arises in the case of musical **sounds.** If two musical pipes or strings of slightly different pitch are sounded together, the result is a more or less distinct throbbing, often disagreeable to the ear. The beat frequency is the difference of the two wave frequencies. Thus, if the two tones are middle-c (256) and c-sharp (271.2), there will be 15.2 beats per sec. If the two tones are **ultrasonic,** but have a frequency difference within the audible range, the beats themselves may produce an audible "beat tone." A similar effect results from the simultaneous reception of two radio wave trains which are nearly, but not quite, synchronized. Thus if two stations are sending on carrier waves of 1000 and 998 kilocycles, the receiver will emit a shrill whistle of frequency 2000 cycles. This is the "heterodyne" effect, responsible for the annoying squeals and tremolos often heard in radio reception. The effect is utilized in heterodyne code receivers and in the frequency-conversion section of the modern radio. One type of radio "fading" may be regarded as a beat phenomenon of long period. (L.D.W.)

BEAUFORT WIND SCALE. In the days of sailing vessels, Admiral Beaufort introduced a wind scale for judging wind force on the sails of a vessel. Beaufort numbers have since then been correlated to a range of wind velocities, and the scale has continued in universal use for describing wind velocity.

Code Number	Wind Velocity (*m.p.h*)	Description
0	0–1	calm
1	1–3	light air
2	4–7	light breeze
3	8–12	gentle breeze

Code Number	Wind Velocity (*m.p.h.*)	Description
4	13–18	moderate breeze
5	19–24	fresh breeze
6	25–31	strong breeze
7	32–38	moderate gale
8	39–46	fresh gale
9	47–54	strong gale
10	55–63	whole gale
11	64–75	storm
12	over 75	hurricane

(P.E.K.)

BEAVER. Mammalia, Rodentia. An aquatic species with webbed hind feet and a broad flat tail. The largest of the North American **rodents**, reaching a length of 3½′ and a weight of 60 lbs. **Capybara.**

The beavers are noted for their extensive building operations. They construct dams of logs, branches and mud in order to form ponds in which their lodges are built. The lodge, like the dam, is a disorderly heap of sticks and mud rising above the water. It contains chambers with entrances below the surface of the water and may be occupied by one animal or by an entire family.

Beavers fell trees for construction and for food by gnawing round and round, although some observers have claimed that they gnaw deeper on the side toward which the tree is to be felled. They store up a supply of logs in their ponds from which the bark is eaten during the winter, although in the warm season they eat other green food.

The fur of the beaver has been among the most valuable on the market and has been the chief reason for a slaughter which threatened to destroy the species With rigid protection they have become numerous in some parts of North America during the present century so the threatened extinction has apparently been averted.

The European beaver, *Castor fiber,* is similar to the North American species, *Castor canadensis;* whether the two are separate species has been a matter of dispute. (A.W.L.)

BECARD. Chatterer.

BECCAFICO. Aves, Passeriformes A bird (**Aves**). This is an Italian name translated fig-eater or fig-pecker, said to apply to the European garden warbler, *Sylvia hortensis.* (A.W.L.)

BÊCHE-DE-MER. Sea Cucumber.

BECKE METHOD. A microscopic method of determining which of two minerals in contact has the higher or lower average index of refraction. (R M F.)

BECKMANN THERMOMETER. Liquid Expansion Thermometers.

BECQUEREL EFFECT. A photographic effect discovered by E. Becquerel (1895). Experimenting with the **daguerreotype** process, Becquerel found that a plate will produce a direct (positive) image if exposed first to diffuse daylight. (C.B.N.)

BED. A supporting member or frame, usually of arc-welded steel or cast iron, such as lathe and planer beds. (H.C.H.)

BEDBUG. Insecta, Hemiptera. A wingless, blood-sucking **bug** which hides during daylight in the crevices of beds and other furniture and about the woodwork of houses and seeks its victims at night. It has been found also about chicken roosts.

Corrosive sublimate (mercuric chloride) dissolved in alcohol and applied to the hiding places of the insects is one method of control. Severe infestations are usually handled by fumigation of the entire building with **hydrocyanic acid** gas, a procedure which demands the services of an expert since the gas is deadly.

This species, *Cimex lectularius,* gives the name bedbug to the family Cimicidae which also contains a few species that attack bats and birds.

Still another member of this order, the large bedbug, is sometimes found in beds. It is almost an inch long and is capable of inflicting a painful wound. This species is one of the **assassin bugs** (Family Reduviidae). (A.W.L.)

BEDDING. A term used by geologists to designate the natural layering or stratification usually characteristic of **sediments** and sedimentary rocks. Bedding is the result of the unequal rates of settling of particles of different sizes and specific gravities. In the case of very fine-grained sediments, or **shales,** the bedding may be shown by color bands. The thickness of a bed or stratum may vary from several feet to a fraction of an inch. Extremely thin beds are called laminae. (R.M.F.)

BEDEN. Ibex.

BEDROCK. The solid rock of the **lithosphere** which may be directly exposed or covered by loose unconsolidated materials such as sand, clay, soil, etc. (R.M.F.)

BEE. Insecta, Hymenoptera. **Insects** which gather nectar and pollen to provision their nests; they are provided with structural adaptations associated with this habit. The term means, to most persons, the **honey-bee,** of the genus *Apis,* unless it is further qualified, but there are many other kinds of bees and a large number of species. Among the solitary bees are the carpenter bees, the leaf-cutting bees, and a number of mining or burrowing species, while the social bees include the honey-bees, the bumblebees, and the stingless honey-bees of the tropical zone. Some species are parasitic in the nests of other bees.

The social life of bees shows structural specialization into castes and reproduction is restricted to a few individuals of the colony, as in other social insects. In the honey-bee colony three castes are recognized, the workers, drones, and queens. The first are abortive females, the second males, and the last functional females. Under normal conditions only a single queen is found in a colony.

Bees illustrate a complete transition from solitary habits to permanent social groups. Some are strictly solitary; some of the burrowing species build their nests independently but in groups; some form a common tunnel with which their individual nests connect; the bumblebees are social during the summer but hibernate as individuals, and the honey-bee colony is permanent.

Their association with flowers makes the bees important in the **cross-fertilization** of many plants. **Red** clover, for example, is cross-fertilized by the bumblebees and for the production of a good crop of seed these insects are necessary. (A W.L.)

BEE FLY. Insecta, Diptera. **Flies** whose habit of visiting flowers for pollen and nectar is like that of the bees. They make up the family Bombyliidae. (A.W.L.)

BEE LOUSE. Insecta, Diptera. A minute, wingless, parasitic **fly** found attached to the queen and drones in honey-bee colonies. The few known species constitute the family Braulidae, containing the genus *Braula.* (A.W.L.)

BEE-EATER. Aves, Piciformes. Brightly colored birds (**Aves**) of the Old World. They have a long curved **beak** and are adept at catching insects in flight. The several species make up the family Meropidae. (A.W.L.)

BEE-MARTIN. Aves, Passeriformes. *Tyrannus.* The common **kingbird** of North America. The name is undeserved, since scientific investigation has disclosed that he eats very few bees. (A.W.L.)

BEE-MOTH. Insecta, Lepidoptera. A **moth** whose **larva** eats the wax and debris in old honeycombs, spinning a silken tunnel as it goes. These insects are found chiefly in weak colonies of bees and in stored combs. They may attack beeswax products, such as comb foundation in the supplies of the apiarist, but they cannot develop on a diet of pure wax; the organic waste in old brood combs provides the necessary nitrogenous material and furnishes a favorable breeding place. The best known form is *Galleria mellonella.*

In well-kept apiaries the bee-moth is rarely a serious pest. The maintenance of strong colonies of bees prevents its entrance and the protection of stored supplies against the entry of the adult moths safeguards them against damage. Fumigation of supplies is sometimes necessary. It may be effectively carried out with **carbon disulfide** but since this compound is highly explosive it must be used with due precautions. (A.W.L.)

BEESWAX. A tough wax formed of a mixture of several compounds, secreted by honey-bees in the form of thin scales from glands on the ventral surface of the abdomen and used in building the combs in which the young are raised and honey and pollen are stored. Commercially it is a compact mass varying from yellowish-white to brownish in color according to its purity. It has a high melting point, near 140° F.

Beeswax is used commercially to make fine candles, in polishing materials, as a component of modeling waxes, and in a variety of other products. See **Esters.** (A.W.L.)

BEET. *Beta vulgaris.* Chenopodiaceae. The many varieties of beets now in cultivation are perhaps all derived from the native *Beta maritima* of southern Europe.

The most important variety is the sugar beet, which in recent years has become an important rival of the sugar cane. As a source of sugar, beets were first utilized in Germany and in France about 1800. In the United States they became important commercially only after the World War. Their culture is still largely restricted to a few states, notably Colorado, Wisconsin, and California.

The sugar beet is a biennial plant which during its first year of growth forms a large tapering tap **root** and a rosette of leaves. At the end of this first year the plant is gathered for sugar production. If allowed to grow the second year, the plant forms a branching stem and an abundance of inconspicuous flowers, utilizing the sugar stored in the root to produce them.

The plant has an elongated tap root which tapers into a long slender root. This may penetrate 4–6′ into the ground. In size and shape the root is extremely variable. Cut transversely, the root is seen to be composed of from 6 to 10 or even more concentric zones. Each zone comprises a ring of conducting cells outside which is a ring of small cells in turn surrounded by a ring of large cells. The small cells are rich in sugar, while the large cells are primarily water-storage cells. The formation of these zones is a consequence of the formation of a succession of **cambium** rings, each of which persists for a few weeks.

In preparing the beets for sugar manufacture, the roots are first lifted from the ground, the leaves cut off, and the roots hauled to the factory. There they are washed thoroughly and cut into thin slices. These slices are put into hot water, which extracts the sugar. The sugar solution is next treated with lime, and then precipitated with carbon dioxide: this removes many impurities which are filtered off. The purified liquor is bleached with sulfur dioxide, and then concentrated by boiling and crystallized under a partial vacuum. From this crude product the molasses is removed by centrifuging, leaving the sugar which is dried and granulated, after which it is ready for the market.

Many of the waste products of beet sugar production are utilized. The tops are used as a stock food either in the raw condition or after preserving as ensilage The beet pulp left after extraction of the sugar is also used as a stock food, as is the molasses from the sugar. Often the pulp and molasses are mixed before feeding. Any refuse from the factory may be used as a fertilizer.

In addition to sugar beets, several other varieties of *Beta vulgaris* are known. One of them is the common table beet, which is eaten either boiled or pickled. When correctly grown it has a minimum of fibrous elements as well as a high sugar content. Most varieties of table beet are deep red in color, in contrast to the white-fleshed sugar beet. Another variety of beet is the Mangel-wurzel or Mangel, of which there are several varieties. They are of large size, have a sugar content varying from 4–8% and are developed principally as a stock food. (R.M.W.)

BEETLE. Insecta, Coleoptera. Any member of this order of insects. The term is often compounded with other words, as rove-beetle, click-beetle, and leaf-beetle. (See **Coleoptera.**) (A.W.L.)

BEGGIATOA. Filamentous forms of sulfur **bacteria** which are capable of converting **hydrogen sulfide** to **sulfuric acid. Sulfur** granules are stored in the cells, and may be oxidized to supply the cell with the necessary energy for life. (R.M.W.)

BEHEMOTH. A biblical name for a large animal, probably the **hippopotamus.** (A.W.L.)

BEISA. Mammalia, Artiodactyla. An **antelope,** *Oryx beisa,* of northeastern Africa, characterized by long sharp horns, ringed at the base and almost straight. With several other species it belongs to the genus *Oryx,* a name often used as a common name for any of the included animals. (A.W.L.)

BEL. This is a unit of power level defined by the following equation:

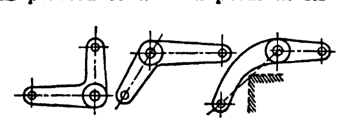
$$\text{bel} = \log_{10} \frac{P_1}{P_2}$$

where P_1 is the power being measured and P_2 is a reference power value (usually arbitrary). The bel is seldom used, as the **decibel** is the common unit for communication power work. (L.R.Q.)

BELEMMITE. Invertebrate Paleontology.

BELL AND SPIGOT. Pipe.

BELL CRANK. A means frequently used to transfer reciprocating motion at right angles is that of a rigid-angled arm pivoted to a fixed point at its vertex, and



Bell cranks.

having hinge connections at its extremities. The bell crank really is a type of **lever,** and the motions of its end are not those of reciprocation, but rather of rotation, but if comparatively long rods are hinged to it, the other ends of those rods will have similar motion. The amplitude of the reciprocation transmitted by the bell crank is

directly proportional to the radii from the pivot point to the joints. (F.T.M.)

BELLADONNA. *Atropa Belladonna.* Solanaceae. The plant grows as a native in Europe and in parts of Asia. It is commonly known as Deadly Nightshade. It is about 3′ tall, and has dull green leaves and purple flowers, which are followed by cherry-like red fruits. Every part of the plant contains the poisonous substance for which it is known. This drug, **atropine,** is a very poisonous **alkaloid** obtained principally from the roots and leaves. Belladonna is used medicinally most often as the tincture. Its action is that of atropine. (R.M.W., R.S.M.)

BELLADONNINE. Alkaloids.

BELL-BIRD. Aves. A term applied to several species of birds (**Aves**) which produce bell-like tones, including a **chatterer** in the Guianas and a **honey-sucker** in New Zealand. (A.W.L.)

BELTING. When the center distance between the axes of parallel shafts is comparatively large, flexible connectors or belts are generally used. Flat belts are generally made of leather, although folded canvas in "plies" impregnated with rubber or with balata gum (a substance obtained from South America) are sometimes used. Flat leather belts are made of oak-tanned or chrome-tanned leather strips cemented together to obtain the required length and thickness. Single leather belts are about 5/16″ thick; double and triple belts are composed of two or three single plies, and are 5/8″ and 7/8″ thick. Belts may be endless, with cemented joints, or they may be joined or laced with wire, rawhide lace, or metal hooks.

Open and crossed belt drives are used for power transmission between parallel shafts; quarter-turn belts may be used when the shaft axes are not parallel. In order for a belt to stay on a pulley, the approaching side of the belt must approach the pulley perpendicular to the axis of rotation of the pulley. By this rule, it may be seen that a quarter-turn belt without an idler pulley will operate satisfactorily for one direction of rotation but will not stay on the pulleys if the rotation is reversed. (By proper use of an idler or "mule" pulley, reversing quarter-turn belt drives can be satisfactorily operated.) By the same rule, open and crossed belt drive shafts should be parallel, with the pulleys in alignment. Narrow belts are often kept on pulleys by means of flanges on the pulley face. Pulleys for wider belts are crowned or slightly greater in diameter at the center than at the edges As the belt seeks the highest point on the pulley, the effect of crown is to keep the belt in a central position.

The speed ratio of a belt drive varies inversely as the pulley diameters. For purposes of estimate, the following, known as the Millwright's Rule, will give the horsepower a belt will transmit:

$$H = WV/K$$

where H is the power transmitted, V is the belt velocity in ft. per min., W is the belt width, in inches, and K is a constant equal to 800 for single and 500 for double belts.

Pulleys are made of cast iron with a rim of rectangular section, and with from 4 to 12 spokes. Two-piece pulleys which are bolted together at the rim and the hub are more expensive than one-piece or solid pulleys, but are easier to install. Steel pulleys built up of pressed steel rims, hubs, and arms, and welded or riveted, are lighter than cast-iron pulleys of the same diameter and face width, and can be run at higher speeds with safety. Pulleys of wood, compressed paper, and compressed fiber are lighter than metal pulleys and have a higher coefficient of friction, and therefore a greater capacity to transmit power for a given belt pull, than metal pulleys.

Vee-belts are made of cords impregnated with rubber, and are of trapezoidal form. They are made in five standard sections varying from section A which is 1/2″ wide and 11/32″ high, to section E which is 1 1/2″ wide and 1″ high. The belts are endless and operate either in two grooved sheaves or in the grooves of a small sheave and on the face of a large pulley (V-flat drives). Vee-belt and V-flat drives offer a satisfactory solution for industrial transmission problems where the center distance is small and the velocity ratio is high, although these are not necessary conditions.

Round leather belt drives are used for light service as in sewing machine drives and similar applications. Like vee-belts, they may be used for misaligned shafting or for quarter-turn drives. Round belts are available commercially in diameters from 1/8″ to 1/2″. (H.C.H.)

BELUGA. Mammalia, Odontoceti. The white **whale,** *Delphinapterus leucas.* A small arctic species which attains a length of 16′ or more. The species has been captured for oil and for its flesh and the hide has been used for leather. (A.W.L.)

BENCH MARK. A definitely established point whose elevation is known in relation to some actual or arbitrary plane is called a bench mark. It is used in **surveying** as a vertical reference point when finding the **elevation** (with respect to an actual or arbitrary plane) of other points of a less permanent nature. The point may be the head of a spike or bolt driven into a tree in such a manner that the top of the head is as nearly horizontal as possible, the highest point on the top of a hydrant, or the top of a flat, non-corrosive plate set securely in stone or **concrete.** Bench marks may be temporary or permanent depending upon their use and should be located so that they are easily accessible for instrument work. (C.W.C.)

BENCH PHOTOMETERS. (See **Photometry.**) The principle underlying the usual forms of bench photometer depends upon finding a point so located between the two light-sources under comparison that the flux densities produced by them at that point are equal. The luminous intensities of the two sources are then proportional to the squares of their distances from that point. To this end, the two sources are mounted near the extremities of the scale of an optical bench, and on a movable carriage between them is some device, called the photometer "head," for receiving and comparing the illuminations from opposite directions.

Among the many types of bench photometer head in use, only four can be mentioned here. A crude form is the Joly "block" screen, composed of two blocks of opal glass or paraffin with an opaque partition between them. When the sides of the blocks are equally illuminated, the two front faces are lighted up equally by diffusion from within. One of the best known types utilizes the Bunsen screen, which is in effect a sheet of white paper with a grease spot at the middle. When the two surfaces are equally illuminated, the grease spot becomes indistinguishable. The Lummer-Brodhun "cube" screen somewhat resembles the Bunsen in principle, but with the paper and grease spot replaced by the interface between two right-angled prisms which are in optical contact only over a central area of some conventional shape. This central area and the area surrounding it merge into a uniform field when the illuminations are equal.

The distinctive feature of the "flicker photometer" head is that, by means of a rotating sector-disk, the two illuminations to be compared are presented to the observer in rapid alternation (but not too rapid), any difference between them being detected as a noticeable

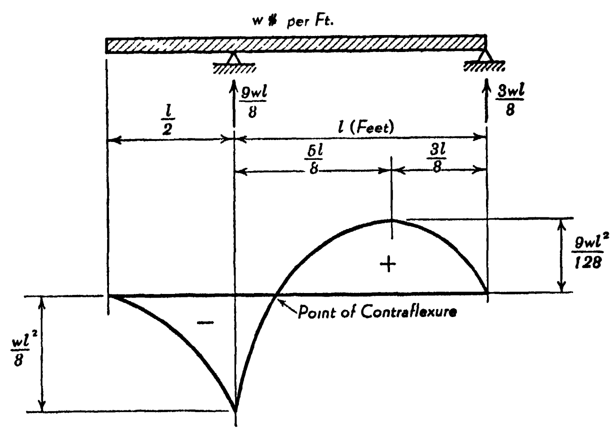
flicker. This type of photometer is especially useful when the sources are not of exactly the same color. (L.D.W.)

BENDING DEFORMATION. **Deformation.**

BENDING LOAD. **Load; Flexure.**

BENDING MOMENT. The external bending moment at any section in a beam is equal to the algebraic sum of the moments, about the gravity axis of the section. This definition assumes that all of the external forces are coplanar, that is, act in one plane. An internal resisting moment at any section is equal to the sum of the moments of the internal **stresses** about the gravity axis of the section. The external bending moment acting on any section is numerically equal to the internal resisting moment but acts in the opposite direction. External moments are positive or negative depending upon the direction in which they tend to rotate the section of the beam under consideration. This sign convention is entirely arbitrary although it is customary in beam analysis to assume that positive moments are those tending to shorten the top surface of the beam while negative moments are those which lengthen the top surface. The point on the longitudinal axis of a beam at which the bending moment changes sign is called the point of contraflexure or the **point of inflection.** Pure bending is a term used to denote the condition where the **shear** is zero over a finite length. It follows that the bending moment is constant over this length. Bending moments have a very important part in beam action since they cause the flexural stresses (see **Flexure**) and are the principal cause of deflections.

A graphical representation of the variation of bending moment on a beam is called a bending moment diagram. An illustration of a bending moment diagram is given below for an overhanging beam with a uniformly **distributed load** covering the entire length of the beam.



Bending moment diagram.

The maximum bending moments which are indicated on the diagram occur where the **shear** changes sign. (See **Shear** for the shear diagram for this beam.) (C.W.C.)

BENDING STRESS. **Stress.**

BENDS. **Caisson Disease (Compressed Air Illness, "The Bends," Diver's Palsy).**

BENEDICT'S SOLUTION. This is an alkaline solution of copper hydroxide and sodium citrate in sodium carbonate used either as a mild oxidizing agent or as a test for easily oxidizable groups such as **aldehyde** groups. The formation of cuprous oxide is a positive test, its color red but often yellow at first. (See **Carbohydrates.**) (R.K.S.)

BENIGN. Harmless; not malignant. This term is usually applied to **tumors** of non-cancerous character. (R.S.M.)

BENT. A transverse frame which forms an integral part of a structural unit or supports another structural unit is called a bent. Bents are designed to carry **lateral** as well as vertical **loads,** and are made of wood or structural **steel.** They are used principally in connection with viaducts and mill buildings. Viaduct bents consist of **columns** held firmly together by bracing in horizontal and vertical planes. The mill building bent is composed of the roof **truss** and the supporting columns which are connected by inclined members called knee braces. These knee braces stiffen the bent against the action of wind forces. Transverse mill building bents are connected by members called purlins and girts in addition to the necessary longitudinal bracing. The purlins rest on the top **chord** of the truss and support the roof while the girts which are connected to the columns are used to carry the siding. (C.W.C., F.T.M.)

BENTHOS. That part of the plant or animal world made up of individuals which rest on a solid support. The term is also applicable to free or attached forms living on the ocean floor. (See **Distribution.**) (A.W.L., R.M.F.)

BENTONITE. The term applied to altered fine-grained volcanic ashes which have been blown considerable distance from their origin and deposited in marine waters. The resulting material is usually a white, but sometimes a colored, clay-like sediment which may contain bits of volcanic glass but is composed mainly of **colloidal silica** which will absorb large quantities of water. Since bentonites are wind-blown deposits they are useful as definite datum planes in **stratigraphy,** especially in helping to determine the contemporanity of the different **facies** of marine sediments. (R.M.F.)

BENZALDEHYDE. Benzaldehyde ("oil of bitter almonds," C_6H_5CHO) is a colorless liquid, boiling point 180° C., of characteristic odor, slightly soluble in water, miscible in all proportions with alcohol or ether, readily oxidized, even on standing in air, to **benzoic acid.** Benzaldehyde reacts with many chemicals in a marked manner, (1) with ammonio-silver nitrate ("Tollen's solution") to form metallic silver, either as a black precipitate or as an adherent mirror film on glass, but does not reduce alkaline cupric solution ("Fehling's solution"), (2) with rosaniline (fuchsine, magenta), which has been decolorized by **sulfurous acid** ("Schiff's solution"), the pink color of rosaniline is restored, (3) with **sodium** hydroxide solution, yields benzyl alcohol and sodium benzoate, (4) with **ammonium** hydroxide, yields tribenzaldamine (hydrobenzamide, $(C_6H_5CH)_3N_2$), white solid, melting point 101° C., (5) with **aniline,** yields benzylideneaniline ("Schiff's base" $(C_6H_5CH{:}NC_6H_5)$), (6) with **sodium** cyanide in alcohol, yields **benzoin** $(C_6H_5 \cdot CHOHCOC_6H_5)$, white solid, melting point 133° C., (7) with **hydroxylamine** hydrochloride, yields benzaldoximes $(C_6H_5CH{:}NOH)$, white solids, anti-oxime, melting point 35° C., syn-oxime, melting point 130° C., (8) with **phenylhydrazine,** yields benzaldehyde phenylhydrazone $(C_6H_5CH{:}NNHC_6H_5)$, pink solid, melting point 156° C., (9) with concentrated **nitric acid,** yields metanitrobenzaldehyde $(C_6H_4CHO(NO_2)(2))$, white solid, melting point 58° C., (10) with concentrated **sulfuric acid,** yields metabenzaldehyde sulfonic acid $(C_6H_4CHO(SO_3H)(2))$, (11) with anhydrous

sodium acetate and **acetic anhydride** at 180° C., yields sodium cinnamate (C_6H_5COONa), (12) with **sodium** hydrogen sulfite, forms benzaldehyde sodium bisulfite ($C_6H_5CHOHSO_3Na$), white solid, from which benzaldehyde is readily recoverable by treatment with sodium carbonate solution, (13) with **acetaldehyde** made slightly alkaline with sodium hydroxide, yields cinnamic aldehyde ($C_6H_5CH{:}CHCHO$), (14) with **phosphorus** pentachloride, yields benzylidine chloride ($C_6H_5CHCl_2$). Benzaldehyde is obtained (1) by boiling the glucoside amygdalin of bitter almonds with dilute acid, glucose plus hydrogen cyanide being formed simultaneously with benzaldehyde, (2) by heating benzal chloride with calcium hydroxide, (3) by heating a mixture of calcium benzoate and formate. Benzaldehyde may be detected by the appearance of a blue color on treating with acenaphthene and sulfuric acid, followed by heating. Benzaldehyde is used (1) as a flavoring essence, (2) in the production of cinnamic acid, (3) in the manufacture of malachite green **dye.** (R.K.S.)

BENZENE. Benzene ("benzol," C_6H_6 or ) is a colorless, odorous liquid, melting point 5.5° C., boiling point 80.1° C., insoluble in water, miscible in all proportions with alcohol, ether, and many organic liquids, dissolves iodine, sulfur, oils, fats, rubber, resins, burns, when ignited, with a smoky flame, the vapor forms with air an explosive mixture, used as a fuel in **internal combustion engines.** Benzene reacts (1) with **chlorine,** to form (a) substitution products (one-half of the chlorine forms **hydrogen chloride**) such as chlorobenzene (C_6H_5Cl), dichlorobenzene ($C_6H_4Cl_2$(1,4) and (1,2)), trichlorobenzene ($C_6H_3Cl_3$(1,2,4)), tetrachlorobenzene (1,2,3,5), and (b) addition products, such as benzene dichloride ($C_6H_6Cl_2$), benzene tetrachloride ($C_6H_6Cl_4$), benzene hexachloride ($C_6H_6Cl_6$). The formation of substitution products of the benzene nucleus, whether in benzene or its homologues is favored by the presence of a **catalyzer,** e g., **iodine, phosphorus, iron,** (2) with concentrated **nitric acid,** to form nitrobenzene ($C_6H_5NO_2$), 1,3-dinitrobenzene ($C_6H_4(NO_2)_2$(1,3)), 1,3,5-trinitrobenzene ($C_6H_3(NO_2)_3$(1,3,5)), (3) with concentrated **sulfuric acid,** to form benzene sulfonic acid ($C_6H_5SO_3H$), benzene disulfonic acid ($C_6H_4(SO_3H)_2$(1,3)), benzene trisulfonic acid ($C_6H_3(SO_3H)_3$-(1,3,5)), (4) with methyl **chloride** plus anhydrous **aluminum** chloride (Friedel-Crafts reaction) to form toluene, monomethyl benzene ($C_6H_5CH_3$), dimethyl benzene ($C_6H_4(CH_3)_2$), trimethyl benzene ($C_6H_3(CH_3)_3$), (5) with acetyl chloride plus anhydrous aluminum chloride (Friedel-Crafts reaction) to form acetophenone, methyl phenyl ketone ($C_6H_5COCH_3$), (6) with **hydrogen** in the presence of a catalyzer, e.g., finely divided nickel, heated, to form dihydrobenzene, cyclohexadiene (1,3)(C_6H_8), a cyclic diolefin hydrocarbon, tetrahydrobenzene, cyclohexene (C_6H_{10}), a cyclic mono-olefin, hexhydrobenzene, cyclohexane (C_6H_{12}), a cyclo paraffin, (7) with ozone, to form benzene triozonide ($C_6H_6(O_3)_3$).

Benzene is obtained from coal tar and coal gas. Coal tar is distilled, the part of the distillate which is insoluble in water is collected up to about 210° C. By fractional distillation of this portion, benzene, **toluene, xylene** are obtained. From coal gas, benzene and toluene, in larger amounts than from coal tar, are obtained by "scrubbing," that is, passing the gas through a special non-volatile absorbing oil, and then distilling off the absorbed oil followed by fractional distillation of this portion. "Ninety per cent benzol" is a commercial benzene product, 90% of which distils over before 100° C. This product contains about 81% benzene, 15% toluene, 2% xylenes. Pure benzene and toluene are obtained by further fractionation. Benzene is used (1) as a **solvent** for many substances, such as oils, fats, resins for varnishes and lacquers, rubber, old paint, and in dry cleaning of fabrics, (2) as a motor fuel, (3) in the manufacture of nitrobenzene for **aniline,** of chlorobenzene for **phenol,** of benzene disulfonic acid for **resorcinol,** of azobenzene for **benzidine,** and of other organic chemicals, especially **dyes.**

Homologues of benzene, e.g., toluene, xylene, ethyl benzene, mesitylene, upon oxidation yield **carboxylic acids,** containing one carboxyl group (—COOH) for each side chain, and substituted side chains behave similarly. (R.K.S.)

BENZIDINE (44′ diaminodiphenyl). Benzidine is an important dye intermediate. (See **Dyes** and **Rearrangements.**) (R.K.S.)

BENZIL. Benzoin, Benzil, and Related Compounds.

BENZOIC ACID AND BENZOATES. Benzoic acid ($H{\cdot}C_7H_5O_2$ or $C_6H_5{\cdot}COOH$) is a white solid, melting point 122° C., boiling point 249° C., insoluble in cold water, soluble in hot water in alcohol, and in ether. Forms benzoates; e.g., **sodium** benzoate, **calcium** benzoate, which, when heated with calcium oxide, yields benzene and calcium carbonate; forms with **phosphorus** trichloride benzoyl chloride (C_6H_5COCl) an important reagent for transfer of the benzoyl (C_6H_5CO—) group; forming meta-chlorobenzoic acid by reaction with **chlorine,** meta-nitrobenzoic acid by reaction with **nitric acid.** The following are esters of benzoic acid:

			°C.
Methyl benzoate . . .	$C_6H_5COOCH_3$	boil. pt.	200
Ethyl benzoate . . .	$C_6H_5COOC_2H_5$	boil. pt.	211
Glycol dibenzoate .	$C_2H_4(COOC_6H_5)_2$	melt. pt.	73
Glyceryl tribenzoate	$C_3H_5(COOC_6H_5)_3$	melt. pt.	76

Benzoic acid may be obtained (1) from some natural products, e.g., gum benzoin, **dragon's blood** resin, Peru and Tolu **balsams,** cranberries, urine of horses; (2) from benzotrichloride by reaction with water when heated; (3) as a by-product in the manufacture of benzaldehyde from benzal chloride or benzyl chloride. Dilute solutions of benzoic acid give a violet coloration with hydrogen peroxide (drop) and ferric chloride, on heating. (R.K.S)

BENZOIN. *Styrax Benzoin.* Styracaceae. (For the chemical compound benzoin, see the article on **Benzoin, Benzil, and Related Compounds.**) Benzoin is a fragrant resin obtained from the bark of a tall quick-growing tree which is native in Sumatra and Java. The tree has alternate entire leaves, the lower surface of which is soft and hairy, the upper smooth. The flowers are borne in compound axillary **racemes;** the fruit is a drupe (see **Fruit**). The **resin** is obtained by making incisions in the bark. From these a thick white juice exudes and hardens. This is scraped off. It is a soft fragrant substance either white or of yellowish color. It is used in medicine as a soothing inhalant and for application to the skin. It contains about 25% **benzoic acid.**

Frequently confused with this is the North American shrub *Benzoin aestivale,* often called Spice bush, which blossoms very early in the spring. All parts of the shrub contain an aromatic substance which is very noticeable when the plant is bruised. (R.M.W.)

BENZOIN, BENZIL AND RELATED COMPOUNDS. (For the resin, benzoin, see preceding article—**Benzoin.**) When **benzaldehyde** (C_6H_5CHO) is warmed with **sodium** cyanide dissolved in alcohol, benzoin ($C_6H_5COCHOHC_6H_5$) white solid, melting point 137° C., is formed, and has the characteristics of a **ketone** and a secondary **alcohol.** Benzoin, (1) upon reduction with sodium amalgam (sodium dissolved in mercury), forms hydrobenzoin ($C_6H_5CHOHCHOHC_6H_5$) white solid, melting point 134° C., mixed with isohydro-

benzoin, melting point 119° C. Hydrobenzoin yields an oxide of the formula ($C_6H_5 \cdot CH—CH \cdot C_6H_5$, with the two CH groups bridged by O), which is known in two stereoisometric forms, symmetrical (inactive) and unsymmetrical (two optically active forms plus a racemic form), (2) upon reduction with zinc plus **acetic acid** or **hydrochloric acid**, forms desoxybenzoin ($C_6H_5COCH_2C_6H_5$), (3) upon oxidation with **nitric acid**, forms benzil, dibenzoyl, diphenyl glyoxal ($C_6H_5COCOC_6H_5$), yellow solid, melting point 95° C., most common alpha-diketone. Two monoximes are known, namely, alpha-benzil monoxime

$$(C_6H_5\underset{\underset{HO—N}{\|}}{C}—CO \cdot C_6H_5),$$

melting point 140° C.; beta-benzilmonoxime,

$$\left(C_6H_5\underset{\underset{N—OH}{\|}}{C}—COC_6H_5\right),$$

melting point 113° C.; and three dioximes, namely anti-benzildioxime $\left(\underset{\underset{HO—N}{\|}}{C_6H_5 \cdot C}—\underset{\underset{N—OH}{\|}}{C \cdot C_6H_5}\right)$, melting point 243° C.; syn-benzildioxime $\left(\underset{\underset{N—OH}{\|}}{C_6H_5C}—\underset{\underset{HO—N}{\|}}{CC_6H_5}\right)$, melting point 206° C.; amphi-benzildioxime

$$\left(\underset{\underset{N—OH}{\|}}{C_6H_5C}—\underset{\underset{N—OH}{\|}}{CC_6H_5}\right),$$

melting point 164° C. When benzil is heated with sodium hydroxide dissolved in alcohol, benzilic acid, diphenylglycollic acid $\left(\underset{HO\ \ COOH}{C_6H_5 \cdot C \cdot C_6H_5}\right)$, melting point 150° C., is formed.

The related hydrocarbons are as follows:

Symmetrical-diphenylethane (dibenzyl)	$C_6H_5CH_2 \cdot CH_2C_6H_5$
Symmetrical-diphenylethylene... (stilbene)	$C_6H_5CH:CHC_6H_5$
Diphenylacetylene...... (tolane) (R.K.S.)	$C_6H_5C:CC_6H_5$

BENZOPHENONE. **Aldehydes, Ketones, and Related Compounds.**

BENZOYL. **Radicals.**

BENZOYL CHLORIDE. **Chlorine.**

BENZYL. **Radicals.**

BERGAMOT OIL. An essential oil (see **Volatile Oils**) produced from the rind of the fruit of *Citrus bergamia*, a relative of the orange and lemon. The small trees are cultivated in southern Europe and bear small yellow fruits. From the skin of these the oil is expressed. This oil is also used to some extent as a clearing agent in the preparation of material for microscopic examination. (R.M.W.)

BERGIUS PROCESS. This is a process of catalytic **hydrogenation of coal and petroleum** under high pressure. (See **Catalysis.**) (R.K.S.)

BERGSCHRUND. **Cirque.**

BERI-BERI. A deficiency disease due to dietary lack of Vitamin B_1, thiamine (see **Vitamins**). Beri-beri has been known for centuries in the Orient, wherever polished rice is the staple diet. It is still a major cause of death in China, Japan and Brazil. In the United States it occurs chiefly in alcoholics who obtain most of their caloric requirements from alcohol and consequently eat a poor diet.

The symptoms of beri-beri are referable to the nervous and cardiovascular systems. The common manifestations are multiple **neuritis**, localized areas of altered skin sensitivity to touch in the extremities, and pain on pressure over large nerves. There is gradual loss of muscle strength, which may lead to paralysis of a limb.

The cardiovascular symptoms and signs are enlargement of the heart, dyspnoea, increased pulse rate, palpitation, and **edema**. If the edema is very extensive, the condition is called wet beri-beri.

Pathologically, degenerative changes are found in the nervous tissue, heart muscle, and gastrointestinal tract. These lesions, however, do not explain the pathologic **physiology** of the disease, which remains obscure.

Treatment is specific, with large doses of thiamine chloride. Since individuals with one vitamin deficiency are very likely to have other deficiencies, patients with beri-beri usually need treatment with other members of the B group. Untreated beri-beri is a fatal disease. (D.M.H.)

BERM. A relatively flat erosion surface brought to grade during a previous cycle of erosion. (R.M.F.)

BERNOULLI DISTRIBUTION. **Bernoulli Probability Function.**

BERNOULLI'S LAW. An important law relating to the flow of **liquids.** Let the attention be fixed upon a small portion of the liquid, whose motion is traced along the line of flow. Then if, at any instant, the elevation of this particle above an arbitrary datum is denoted by e (cm.), the pressure upon it by p (dynes per sq. cm.), the speed at which it moves by v (cm. per sec), and the density of the liquid by ρ (grams per cm.^{3}, supposed constant), the total "head" of the liquid at this point is given by Bernoulli's equation as

$$e + \frac{p}{\rho g} + \frac{v^2}{2g} = H.$$

g is the acceleration of gravity (cm. per sec. per sec.). In hydraulics the three terms of the first member are commonly called respectively the "elevation head," the "pressure head," and the "velocity head." Bernoulli's law states that if the flow takes place without external interference, that is, without any work being done by or upon the liquid as it flows (an ideal condition, of course), then the total head H remains unchanged throughout the flow; a fact which follows from the principle of conservation of energy.

Special cases arise when any one of the three terms is kept constant. Thus if the flow is horizontal, so that e is constant, an increase in speed necessitates a decrease in pressure, a principle utilized in the Venturi meter. Many of the theorems of **hydrokinetics**, such as Torricelli's, may be derived from Bernoulli's law. (L.D.W.)

BERNOULLI PROBABILITY FUNCTION. If the **probability** of success, p, is constant from trial to trial and if these trials are independent, then we obtain a Bernoulli series and the distribution of successes is called a Bernoulli probability function. Let P_x be the probability of obtaining x successes in s trials, then $P_x = {}_sC_x p^x q^{s-x}$. The mean is sp, $\sigma_x = \sqrt{spq}$, $\alpha_{3:x} = \dfrac{q - p}{\sqrt{spq}}$, and $\alpha_{4:x} = 3 + \dfrac{1 - 6pq}{spq}$. The mean of the proportion of successes, $\dfrac{x}{s}$, is p, $\sigma_{\frac{x}{s}} = \sqrt{\dfrac{pq}{s}}$, $\alpha_{3:x} = \alpha_{3\frac{x}{s}}$, $\alpha_{4:x} = \alpha_{4:\frac{x}{s}}$.

The Bernoulli probability function is of frequent occurrence. (See **Bernoulli's Theorem; the De Moivre-Laplace Theorem.**) (L.A.A.)

BERNOULLI'S THEOREM. Ths theorem was published posthumously in 1713. Let the **probability** of an event p be constant from trial to trial, and the probability of failure be denoted by q. Let the **relative frequency** be denoted by $\frac{x}{s}$ where x is the number of successes in s trials. Let $P\left(\left|\frac{x}{s} - p\right|\right)$ denote the probability of obtaining the absolute value of the deviation $\frac{x}{s} - p$. Usually this deviation will be small. Bernoulli's theorem states that as the number of trials s increases, the probability of a difference in absolute value more than a stated positive amount ϵ approaches zero. In symbols

$$\lim_{s \to \infty} P\left(\left|\frac{x}{s} - p\right| > \epsilon\right) = 0.$$

It should be clear that the theorem does not state

$$\lim_{s \to \infty} \frac{x}{s} = p.$$

The theorem states roughly that if s is sufficiently large usually $\frac{x}{s}$ will not differ much from p. However, cases may occur though quite infrequently when $\frac{x}{s}$ will differ considerably from p. Bernoulli's theorem is one of the **"laws of large numbers."** It is exceedingly important in all problems of modern sampling theory and is the basis of many practical problems, particularly when p is unknown and must be estimated in some way. (L.A.A.)

BERRY. A berry is a fruit in which the entire ovary becomes soft and fleshy, as in tomatoes and grapes. Frequently, as in currants and gooseberries, the calyx tube grows around this ovary wall and forms the skin of the berry. Strawberries, raspberries, mulberries, and so forth, are not berries in the botanical sense.

Many other fruits are closely related to berries, but are distinguished by special names. For example, melons, squashes and gourds are berries with a hard outer shell, and are called pepos, while a citrus fruit, such as an orange, lemon or grapefruit, etc., differs in having a tough leathery rind, and so is a modification of berry known as a hesperidium. (R.M.W.)

BERTRAND LENS. A small lens used in the petrographic microscope for magnifying the **interference figure.** (R.M.F.)

BERYL. The mineral beryl is a silicate of **beryllium** (glucinium) and **aluminum** corresponding to the formula $Be_3Al_2(SiO_3)_6$. Crystallizing in the **hexagonal system** the 6-sided prisms of beryl may be very small or range up to several feet in length and a yard or so in diameter. Terminated crystals are relatively rare. Its fracture is **conchoidal;** hardness, 7.5–8; specific gravity, 2.63–2.80; colors, emerald green, green, blue-green, blue, yellow, red, white and colorless; luster, vitreous; transparent to translucent. The mineral beryl has long been used as a gem, the emeralds being a rich green variety, colored probably by minute amounts of some chromium compound. A beautiful bluish sort is called aquamarine; morganite is pink, and the golden beryl is a clear bright yellow. Other shades like honey yellow and yellowish-green are common. Beryl is found in granite rocks and especially in pegmatites, but it occurs also in mica schists in the Urals. In addition to the many European localities as Austria, Germany, Ireland, etc., beryls of gem quality are found in Africa, Madagascar (especially for morganite), and Brazil. The most famous place in the world for emeralds is at Muso, Colombia, South America, where they form a unique occurrence in limestones. Emeralds are also obtained in the Transvaal and near Mursinsk, in Siberia. In the United States, New England has furnished much beryl from its pegmatites and for a long time the huge crystals from Acworth and Grafton, New Hampshire, were the largest known. Recently, however, giant crystals even larger than those from New Hampshire were discovered in Albany, Maine, the largest of which was 18′ long, 4′ through, and weighed about 18 tons. Other localities are Paris and elsewhere in Oxford County, Maine; Royalston, Massachusetts; North Carolina, Colorado, South Dakota, and California. Metallic beryllium (glucinium) is obtained from beryl. Its lightness and strength make it very valuable for industrial purposes. Alloyed with copper in small amount, it confers extraordinary properties on the copper. The word beryl comes from the **Greek** meaning the gem beryl. (E.S.C.S.)

BERYLLIUM OR GLUCINIUM. Symbol: Be. Atomic number: 4. Atomic weight: 9.02. Density: 1.84. Melting point: 1350°. No isotope, but single atomic form: 9 (99.95%).

Beryllium is a silver-white, hard, malleable metal of markedly low density. Beryllium is only slightly affected by water or cold **nitric acid,** but is readily dissolved by hot nitric acid, by **hydrochloric** or dilute sulfuric acid, and by **sodium** hydroxide solution; and when ignited in air forms beryllium oxide. Chemically related to **magnesium** and **aluminum.** Discovered by Vauquelin in 1797. On account of the lightness, strength, hardness and resistance to corrosion of alloys of beryllium extensive investigations have been undertaken with a view to its more common use. Two per cent beryllium in copper is used as material for springs.

Beryllium occurs in beryl (11%–13% BeO) in the New England states, also in South Dakota and Colorado, in South Africa, Madagascar, Austria, and France. The Copaux method of extraction consists in heating the beryllium aluminoscilicate (beryl) with **sodium** silicofluoride, and later extracting with hot water, whereupon the beryllium salts are dissolved and thus separated from the other constituents. **Electrolysis** of fused beryllium chloride at 700° C., a temperature below the melting point of beryllium metal, or of fused beryllium oxyfluoride mixed with barium fluoride at 1400° C., a temperature above the melting point of beryllium metal, are methods used to secure the metal.

Hydroxide: Beryllium hydroxide ($Be(OH)_2$), white, gelatinous precipitate by the reaction of **ammonium** hydroxide or sulfide with beryllium salt solutions. This precipitate, while formed similarly to **aluminum** hydroxide, differs from the latter in being formed also by boiling a solution of beryllate, thus furnishing a separation from aluminum by boiling in sodium hydroxide (of 5 normal concentration).

Oxide: Beryllium oxide (BeO), white solid, by ignition of the nitrate, hydroxide, or of the metal in air; an excellent refractory material, melting point 2450° C.; used in small amount in the mixture of oxides of **thorium** and **cerium** in the incandescent gas mantle.

Beryllium dimethyl ($Be(CH_3)_2$), snow-white solid, sublimes at 200° C., and beryllium diethyl ($Be(C_2H_5)_2$), colorless liquid, of melting point 12° C. and boiling point at 15 mm. pressure, 110° C., both compounds spontaneously inflammable in air, have been prepared by Gilman and Schulze (1927). (R.K.S.)

BERYLLONITE. A mineral composed of the **rare sodium beryllium phosphate,** which crystallizes in the **orthorhombic** system with short prismatic or tabular crystals. Cleavage, perfect basal; hardness, 5–5.6; specific gravity, 2.8; luster is vitreous to somewhat pearly on the base; colorless to white or yellowish. Attempts to make use of this mineral as a gem stone were unsuc-

cessful owing to its relative softness. Beryllonite is found at Stoneham and Newry, Oxford County, Maine. (E.S.C.S.)

BESSEL FUNCTIONS. The **differential equation**

$$x^2\frac{d^2y}{dx^2} + x\frac{dy}{dx} + (x^2 - n^2)y = 0$$

is called **Bessel's** equation. It cannot be solved in terms of elementary functions. It defines a new class of functions, the Bessel functions of the first kind, denoted by $J_n(x)$, and those of the second kind, denoted by $K_n(x)$. These functions are also sometimes called cylindrical functions.

The functions $J_n(x)$ may be defined by the convergent series

$$J_n(x) = \sum_{k=0}^{\infty}\frac{(-1)^k x^{n+2k}}{2^{n+2k}k!\Gamma(n+k+1)},$$

and the functions $K_n(x)$ by the convergent series

$$K_n(x) = J_n(x)\cdot\log x - \frac{1}{2}\sum_{k=0}^{n-1}\frac{(n-k-1)!x^{-n+2k}}{2^{-n+2k}k!}$$

$$-\frac{1}{2}\sum_{k=0}^{\infty}\frac{(-1)^k x^{n+2k}}{2^{n+2k}k!(n+k)!}\cdot[H_k + H_{k+n}],$$

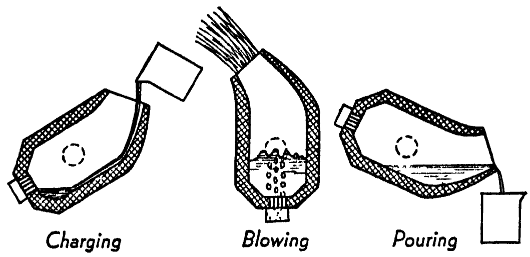
where $H_k \equiv 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{k}$. When n is an integer, the series for J_n may be written

$$J_n(x) = \frac{x^n}{2^n\cdot n!}\left[1 - \frac{x^2}{2(2n+2)} + \frac{x^4}{2\cdot 4(2n+2)(2n+4)} - \frac{x^6}{2\cdot 4\cdot 6(2n+2)(2n+4)(2n+6)} + \cdots\right].$$

When n is not an integer, the general solution of Bessel's differential equation is $y = c_1J_n(x) + c_2J_{-n}(x)$, where c_1 and c_2 are arbitrary constants. When n is an integer, the general solution is $y = c_1J_n(x) + c_2K_n(x)$, where c_1 and c_2 are arbitrary constants. (L.L.S.)

BESSEMER PROCESS. The Bessemer process is one of four methods for making **steel**, the others being the crucible, the open hearth, and the electric processes. The pig iron (see **Blast Furnace**) used in the manufacture of steel must be refined to eliminate the impurities. The refining operation consists largely of oxidation of the impurities to effect their removal. In 1856 Sir Henry Bessemer gave the world his process for converting pig iron into steel. The Bessemer process is based on blowing compressed air through a mass of molten iron. On its way through the **iron**, the **oxygen** in the air combines with the **silicon, manganese**, and **carbon** in the iron, oxidizing them with the production of considerable heat. The "blow," as this oxidizing action is called, consumes only a short time, perhaps from 10 to 30 minutes. During this period the progress of the oxidation of the impurities is judged by the appearance of the flame issuing from the mouth of the converter. The use of photo-electric methods of recording the characteristics of the flame has greatly aided the "blower" in controlling the final quality of the product. After the blow, the liquid metal is recarburized to the desired point, and sometimes other alloying materials added, dependent on whether plain carbon steel or **alloy** steel is to be the final product. Spiegeleisen, a low grade ferromanganese, high in carbon, is largely used in the manufacture of Bessemer steel.

The Bessemer converter is often built in the form of a pear-shaped vessel having the top opening inclined towards the side. Tuyère openings for air are placed in or near the bottom of the converter, and the whole is mounted on trunnions so that it may be rotated into one or the other of three different positions, namely,



Bessemer converter.

inclined so that the opening is vertical for charging, upright during the blow, and horizontal for discharge of the finished product. The converter shell is made of steel plate and castings, and is lined with a **refractory** lining which may be either acid or basic, depending on the composition of the pig iron. Raw iron with low phosphorus and sulfur is readily refined, by the blowing process just described, in a converter lined with a siliceous material such as ganister. If the pig iron has considerable **phosphorus** and **sulfur** it is necessary to use a lining which has the proper fluxing characteristics, since phosphorus and sulfur are not readily removed by oxidation. Some of the materials for linings of the converter for the basic Bessemer process are mixtures containing limestone (**calcite**) and fire clay, **magnesite**, or calcined **dolomite**.

In the operation of the Bessemer converter it is necessary to have the whole charge and the converter intensely hot before beginning the blow. To this end the pig iron is either conveyed directly to the converter from the blast furnace, or is remelted in a cupola. The converter is prepared by firing with coal or oil until the lining is white hot After the blow the iron is recarburized, and alloying elements are added and thoroughly mixed by stirring with a long iron bar and rocking the converter. (F.T.M., R.H H.)

BETA FUNCTION. The beta function is a mathematical expression; it is one of the **transcendental functions** which occurs first in the advanced part of **calculus**. It is also sometimes called an Eulerian integral of the first kind.

The **improper integral**

$$B(m, n) = \int_0^1 x^{m-1}(1-x)^{n-1}dx \quad (m > 0, n > 0)$$

defines a **function** of m and n which is called the beta function. It can be expressed in terms of the **gamma function** by

$$B(m, n) = \frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n)}.$$

(L.L.S.)

BETA PARTICLES. Beta Rays. **Radioactive Changes.**

BETATRON. **Cyclotron.**

BETEL NUT. The fruit of the Areca palm, ***Areca Catechu***. The Areca palm, a plant native to Malaya, is extensively cultivated in the southern Asiatic countries and in the East Indian Islands. It is a slender unbranched tree which reaches a height of 40′ with a trunk diameter of 3 or 4″, and bears at its top a crown of 6–10 large leaves. The fruit is slightly more than an inch in diameter and has a fibrous rind surrounding the very hard seed. This seed is extensively chewed in Asiatic countries. To prepare them for chew-

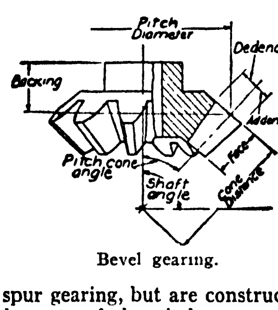
ing, the fruits are gathered just before maturity, boiled, sliced and dried. A piece of this dried fruit, together with a bit of lime, is wrapped in a betel leaf and the whole placed in the mouth. Chewing this preparation causes an abundant flow of saliva which is colored brick-red and stains the mouth, as well as blackening the teeth. The betel leaves are obtained from an entirely different plant, the Black **Pepper**, *Piper betel*. (R.M.W.)

BETELGUEZE. Betelgueze (**α Orionis**) is a contraction of an Arabic phrase indicating that this star is the "armpit of the central one," i.e., the armpit of Orion. Because of its rich reddish color the star has frequently been referred to as the "martial one," and in **Astrology** portends military or civic honors. Because it is the first star to rise of the brilliant and well known **constellation** of Orion, the title of "roarer" or "announcer" has been assigned to it by ancient writers.

Betelgueze is of great interest astronomically. It is an irregular **variable** star. It is also one of the first stars to have its diameter measured with the stellar **interferometer.** The diameter is found to be variable between 260,000,000 and 180,000,000 miles. At maximum diameter the star would extend out beyond the orbit of **Mars** if put in the sun's place. (W.K.G.)

BEVEL GEARING. Straight-tooth and spiral-tooth bevel gearing are used to transmit motion between shafts whose axes intersect. The operation of such units is analogous to that of friction cones, which may be considered to represent the pitch cones for the bevel gearing, and which correspond to pitch cylinders for spur gearing. Straight-tooth bevel gears have teeth of involute form, but the straight-line elements converge (if extended) at the intersection of the shaft axes, in contrast to the parallel-tooth elements of spur gears. There are several forms of bevel gearing; in the most important, the gear and pinion operate at a shaft axes angle of 90°. The unit is termed miter gearing if both gear and pinion have the same number of teeth, and angular gearing if the angle between the shaft axes is less than 90°. Bevel gearing in which the shaft axes angle is greater than 90° is also used to some extent. The pitch cone angles of the pinion and gear must be complementary for a shaft axes angle of 90°.

The pitch diameter of bevel gearing is measured at the large end of the pitch cones; the addendum and dedendum are not measured in the plane of the pitch



Bevel gearing.

circle, as in spur gearing, but are constructed perpendicular to the elements of the pitch cone on the surface of the back cone. The tooth shape is therefore dependent upon the magnitude of the back-cone radius, rather than the pitch radius, as in spur gearing.

Mortise gears have cast-iron rims with cored slots into which hard maple cogs or teeth are fitted and held in place by wedges at the back of the rim, and are designed to operate with cast iron cast tooth pinions. Cast-tooth gearing, however, is used only where the pitch-line velocity is low and where smooth action is not particularly important.

Spiral bevel gears have teeth cut in the arc of a spiral across the gear face, and bear the same relation to straight bevel gears that helical gears do to spur gears. This construction results in a larger number of teeth in contact than in straight-tooth bevel gearing, and like helical gearing, permits higher pitch-line velocities and greater load-carrying capacities for the same occupied space. They are often used to replace straight-tooth bevel gear sets.

Hypoid gearing resembles spiral bevel gearing in general appearance, but is used for transmitting power between shafts whose axes are perpendicular, but non-intersecting. They find wide-spread application in automobile rear-axle drives, and in numerous other instances where bevel or worm gearing is not applicable. (H.C.H.)

BEVEL PROTRACTOR. Measurement.

BHARAL. Mammalia, Artiodactyla. The blue **sheep,** *Pseudois nayaur,* of Tibet. The species is closely related to the goats. (A.W.L.)

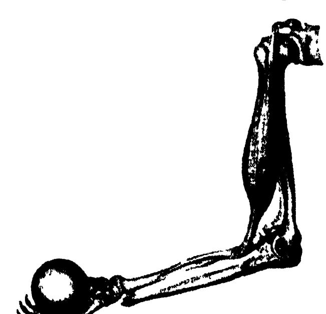
BIAS. A **statistic** θ' is said to be unbiased if the expected value of θ' equals the population value θ. A statistic which is not unbiased is biased. Bias in this sense should not be confused with the idea of a **consistent statistic.**

Bias is also sometimes used in the sense of an **error** in the observations, or in an error in the mean caused by persistent errors in the same direction. This notion is not the one usually considered when we say a statistic is biased.

In electrical work this term is used to denote a voltage whose principal function is to locate the operating point on the characteristic of a piece of apparatus The term is most commonly applied to the grid voltage of a vacuum **tube,** in which case it means the d-c voltage (other than signal voltage) applied between the **cathode** and control **grid** of the tube. In this connection the term C-bias is also commonly used The bias may be obtained from a source of d-c voltage, from the potential drop across a resistor (cathode resistor) in the cathode circuit or, when the grid carries current, from the drop across a resistor in the grid circuit The first method is called fixed bias and the latter two self-bias. Bias is also used in **telegraphy** to indicate undesirable voltage additions to or subtractions from the code signals. (L.A.A., L.R.Q.)

BIAXIAL CRYSTALS. Double Refraction.

BICEPS. Any of several **muscles** with two heads. The principal examples are (1) the biceps femoris which,

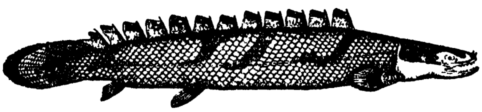


Biceps muscle contracting forearm.

in man, lies in the back part of the thigh and flexes the lower leg, and (2) the biceps of the upper arm which flexes the lower arm. (A.W.L.)

BICHIR. Pisces, Chondrostei. An air-breathing fish, *Polypterus,* found in the Nile, one of a few living representatives of a group which was once abundant and is supposed to have been ancestral to the bony fishes. It

was formerly thought that *Polypterus* belonged to the Crossopterygii, a group of fish (**Pisces**) ancestral to the terrestrial vertebrates. (A.W.L.)



Bichir.

BICUSPID. A tooth with two cusps, especially the premolars of man. (A.W.L.)

BIELIDS. Bielids or Andromedes are the names applied to a **meteor shower** which is observed about November 24th of each year. The **radiant point** of the shower is in the **constellation** of **Andromeda.**

The history of the Bielids and their connection with **Biela's Comet** is one of the interesting chapters in the development of meteoric astronomy. Biela's Comet was first discovered in 1772 but was not found to be periodic. In 1826 Biela discovered the comet again and it now bears his name. Its **orbit** is elliptical with a period of about 6 years. In 1832 the comet passed very close to the earth. In 1845 the comet was observed to break in two, and in 1852, at the time of the predicted return, it was found that the two parts of the comet were both very faint and separated by over a million miles. They were unfavorably located relative to the sun for observation in 1859, and at the time of the return in 1866 they were not to be found.

The first mention of a swarm of meteors located on the orbit of Biela's comet is found in the display of December 5, 1741, when a brilliant shower was observed in Russia. They were observed during December in 1798, 1830, and 1838. By this time calculations of the radiant point had been made and it was first located, apparently, in **Cassiopeia.** By 1867 the date of the shower had shifted to November and it has always been observed in that month since that year. Up to 1885, many brilliant meteors were associated with the radiant point with from two to four observers on November 27 of that year observing no less than 39,546 meteors in 4 hours and 8 minutes. Since 1899, but very few members of the shower have been observed and it is evident that **perturbations** have shifted the orbit of the main swarm well outside the orbit of the earth. (W.K.G.)

BIENNIAL. Many plants, including some of the commonest cultivated ones, require 2 years of growth to complete their life-cycle. Such plants are called biennial. During the first year of growth they commonly form a close rosette of leaves growing from a very short stem and spreading out close to the ground, or form a head (as in the **cabbage**), and develop a thick tap root in which is accumulated a considerable amount for food reserves. During the second year of growth this reserve food is drawn upon to permit the development of a tall stem and flowers and fruit. **Beets** and **carrots** are examples of biennial plants in which the root rich in stored food reserves becomes an important source of food for man. (R.M.W., B.S.M.)

BIGHORN. Mammalia, Artiodactyla. *Ovis* The mountain **sheep,** ranging from Alaska to Mexico and eastward into the bad lands of South Dakota. Several species and varieties are recognized in different parts of this range. (A.W.L.)

BILATERAL TOLERANCE. Interchangeable Manufacture.

BILE. Bile is a secretion of the **liver,** alkaline in reaction, yellow, brown or green in color. It consists of water, **bile salts** (sodium glycocholate and sodium taurocholate), inorganic salts, bile pigments (see **Pyrrole and Related Compounds**), **cholesterin,** and lecithin (see **Aminoacids, Polypeptides, and Proteins**). About a quart of bile is secreted every 24 hours, the quantity depending on the amount and kind of food eaten.

The bile salts are important; they stimulate the liver and have other functions of which little is known. After being secreted in the bile, the bile salts to a large extent are reabsorbed in the intestine and resecreted by the liver. The amount of bile pigments present determines the color of the bile.

The action of bile in the **digestion** of food is concerned with **fats.** Bile, plus the action of the **pancreatic** secretion, serves to break down the fats to **glycerin** and fatty acids. Fat soluble viatmins A, D, and K cannot be well absorbed without bile. Bile is also supposed to have an antiseptic action in the intestine, preventing putrefaction. Other functions of bile are not definitely known.

The bile is secreted by the liver into the biliary channels in the liver which enter the common bile duct. The bile duct enters the **duodenum** where a muscular **sphincter** controls the amount of flow into the intestine. Fatty foods and certain drugs cause the sphincter to open so that more bile escapes into the intestine.

If the flow of bile is prevented through obstruction, by stone formation, or by swelling of the bile duct walls from infection, the bile backs up and is absorbed by the blood stream and carried throughout the system. Such a condition results in **jaundice.** The same results follow if sufficient number of the smaller bile channels in the liver are obstructed. (R.S.M., D.M.H.)

BILL. The **beak** of a bird. (A.W.L.)

BILLFISH. Pisces, Teleostei. The garfish (**Pisces**), a marine species found from Massachusetts to Texas and ascending the rivers. Not to be confused with the garpikes or gars. (A.W L.)

BINARY GRANITE. A granite containing only the essential minerals quartz and feldspar. Also used to describe granites which contain **muscovite** and **biotite** micas. (R.M.F.)

BINARY STARS. The term binary star was apparently first introduced by Sir William Herschel in 1802 to designate "a real double star—the union of two stars that are formed together in one system by the laws of attraction." At present, binary stars are classified under three headings: **visual binaries, spectroscopic binaries,** and **eclipsing binaries** under which headings the characteristics of the different types will be found discussed elsewhere in this work.

During the past 150 years a large amount of research has been carried out on the binary systems leading to certain general conclusions. It is believed that at least ¼ of all stars are at least binary systems, with a considerable percentage, possibly as great as 10%, of these systems multiple systems, i.e., containing more than two stars. There is a direct correlation between the period of revolution of a binary star and the eccentricity of its **orbit,** with the systems of short period having the smaller eccentricities. There is a regular gradation from pairs with short period in which the stars are practically in contact up to pairs so widely separated that the physical connection is only indicated by their common **proper motion** through space. Finally, in pairs in which the components are equal in brightness both stars have the same **spectral type,** while in systems where the brightnesses are different the fainter star is bluer if the brighter star is a **giant;** and redder if the brighter star belongs to the main sequence.

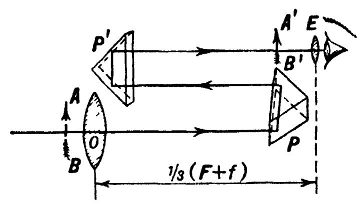
Since mass can be determined only from **gravitational** attraction and the only stars (with the exception of the **sun**) for which gravitational attraction can be determined are the binary stars, these objects form the one

group from which the masses of stars may be determined. In the case of a visual binary star, after the orbit has been determined and the **stellar parallax** of the system obtained, the combined mass of the two stars may be obtained by a direct application of the **Keplerian Harmonic Law.** Unfortunately, it is impossible to obtain the complete orbit of a spectroscopic binary unless it is also a visual or an eclipsing binary; so from these objects a determination of mass is impossible except on the basis of a statistical discussion. In the case of those eclipsing binaries which are also spectroscopic binaries it is possible to make a complete solution for the specifications (i.e., masses, densities, sizes, luminosities, and approximate shapes) of both members of the system. From such objects, and only from such objects, may the complete characteristics of individual stars be determined. (W.K.G.)

BINNACLE. The stand for supporting and protecting the **compass** on board a ship is known as the binnacle. This stand is usually constructed of brass and is provided with a shaded light which illuminates the compass during the night, but does not shine in the eyes of the helmsman.

In addition to protecting the compass from effects of weather, the binnacle also contains a number of fixed and adjustable magnets and masses of soft iron for the purpose of partially compensating for the effects of the **magnetic field** of the ship. The process of adjusting the various compensating devices is known as compass adjusting and is usually carried on by experts while a ship is in port. (W.K.G.)

BINOCULAR. An instrument composed of two similar **telescopes,** one for each eye, usually with focusing tubes controlled by a common screw adjustment. The ordinary opera glass is a binocular utilizing Galilean telescopes. The field glass employs erecting telescopes of the spy-glass type. A well-known modern form is the "prism binocular." The special feature of this instrument is a pair of right-angled, **total reflection** prisms



Optical system of prism binocular (*Weld and Palmer, Textbook of Modern Physics, Blakiston*)

in each telescope, which contribute three advantages. 1. The prisms, by means of two double total reflections in planes at right angles, accomplish the erection of the image without additional lenses. 2. The tube is rendered much shorter than in the ordinary field glass of equal power by the "doubling up" of the rays due to the reflections. 3. The objectives are by the same means set farther apart than the eyepieces, thus increasing the "stereo power" of the instrument as a binocular, so that objects can be seen to have depth or solidity at a greater distance than with the ordinary type. (See **Binocular Vision.**) (L.D.W.)

BINOCULAR VISION. The possession of two **eyes** set at a distance apart, but with approximately parallel axes, enables us to obtain two views from slightly different angles, and thus to become sensible of the solidity of single objects and to get an idea of the actual distribution of different objects in space. To become vividly conscious of this faculty, one has only to look about the room for a time with a hand cupped over one eye, and then suddenly to remove the hand. If the vision is reasonably normal, it will be noticed that with one eye only the scene appears flat, like a photograph, but as soon as both eyes are used, objects spring into clear relief. In some manner the brain is able, through long experience, to blend the two different sensory pictures from the two different **retinal** images and to interpret the resulting sensation in terms of geometrical solidity. There is, however, a limit to the distance at which this impression is perceptible, and for very distant objects other factors must be relied upon, such as the apparent size (as of buildings or trees), or the opacity of the atmosphere (as in viewing distant mountains). In the absence of such factors, no estimate of distance can be formed; thus the stars all appear to be at the same distance. This limiting "stereoscopic radius" is for normal, unaided eyes, only a few hundred feet, but with a **binocular** telescope, and especially with a prism binocular, it is increased in a ratio called the "stereo power" of the instrument.

An interesting aspect of the subject is the use of binocular pictures and the stereoscope. Two photographs or drawings are prepared of the same group of objects from viewpoints approximately the same distance apart as the human eyes (say about 2¾") and mounted side by side on a card so that each is viewed separately by the eye to which it corresponds; the observer gets the sensation of viewing a 3-dimensional scene. The observation is facilitated by a pair of lenses so designed as to allow of focusing the eyes for distance, and with a diaphragm set up between them to avoid seeing both pictures with either eye. This arrangement is the stereoscope. (L.D.W.)

BINOMIAL COEFFICIENTS. **Binomial Formula.**

BINOMIAL FORMULA. The binomial theorem gives a formula expressing any **power** of a binomial $a + x$ in terms of powers of a and x.

Binomial Theorem: If n is any positive integer, the expansion of $(a + x)^n$ is given by:

$$(a + x)^n = a^n + na^{n-1}x + \frac{n(n-1)}{2!}a^{n-2}x^2 + \frac{n(n-1)(n-2)}{3!}a^{n-3}x^3 + \cdots + \frac{n(n-1)(n-2)\cdots(n-r+1)}{r!}a^{n-r}x^r + \cdots + nax^{n-1} + x^n,$$

where there are $n + 1$ terms on the right. If n is not a positive integer, the binomial expansion becomes an **infinite series:**

$$(a + x)^n = a^n + na^{n-1}x + \frac{n(n-1)}{2!}a^{n-2}x^2 + \cdots + \frac{n(n-1)(n-2)\cdots(n-r+1)}{r!}a^{n-r}x^r + \cdots$$

which is convergent for $|x| < |a|$.

The symbol $m!$, called factorial m, is the repeated product $1 \cdot 2 \cdot 3 \cdots m$ of all the positive integers from 1 to m inclusive; it is also sometimes denoted by $\underline{|m}$.

The r^{th} term (general term) of the binomial expansion $(a + x)^n$ is:

$$\frac{n(n-1)(n-2)\cdots(n-r+2)}{(r-1)!}a^{n-r+1}x^{r-1};$$

sometimes the general term is taken as the $(r + 1)st$ term

$$\frac{n(n-1)(n-2)\cdots(n-r+1)}{r!}a^{n-r}x^r.$$

The coefficients in the binomial expansion are called binomial coefficients. They are often denoted by th symbols $1, \binom{n}{1}, \binom{n}{2}, \cdots, \binom{n}{r}, \cdots$, so that

$$\binom{n}{r} = \frac{n(n-1)(n-2)\cdots(n-r+1)}{r!}.$$

By the formula for **combinations**, it follows that $\binom{n}{r} = {}_nC_r$.

The binomial theorem is often written:

$$(1+x)^n = 1 + \binom{n}{1}x + \binom{n}{2}x^2 + \binom{n}{3}x^3 + \cdots + \binom{n}{r}x^r + \cdots$$

in terms of the binomial coefficient notation.

The binomial coefficients may be arranged in an interesting scheme called Pascal's triangle:

$$\begin{array}{ccccccccccccccccc}
&&&&&&&&1&&&&&&&&\\
&&&&&&&1&&1&&&&&&&\\
&&&&&&1&&2&&1&&&&&&\\
&&&&&1&&3&&3&&1&&&&&\\
&&&&1&&4&&6&&4&&1&&&&\\
&&&1&&5&&10&&10&&5&&1&&&\\
&&1&&6&&15&&20&&15&&6&&1&&\\
&1&&7&&21&&35&&35&&21&&7&&1&\\
1&&8&&28&&56&&70&&56&&28&&8&&1\\
\cdots&&\cdots&&\cdots&&\cdots&&\cdots&&\cdots&&\cdots&&\cdots&&\cdots
\end{array}$$

where each row of numbers represents the binomial coefficients of a certain power of a binomial.

The binomial formula gives the following important approximation:

$$(1 + x)^n \approx 1 + nx$$

if x is sufficiently small; special cases are:

$$(1 + x)^2 \approx 1 + 2x, \qquad (1 - x)^2 \approx 1 - 2x,$$
$$(1 + x)^3 \approx 1 + 3x, \qquad (1 - x)^3 \approx 1 - 3x,$$
$$\frac{1}{1+x} \approx 1 - x, \qquad \frac{1}{1-x} \approx 1 + x,$$
$$\sqrt{1+x} \approx 1 + \tfrac{1}{2}x, \qquad \sqrt{1-x} \approx 1 - \tfrac{1}{2}x,$$
$$\frac{1}{\sqrt{1+x}} \approx 1 - \tfrac{1}{2}x, \qquad \frac{1}{\sqrt{1-x}} \approx 1 + \tfrac{1}{2}x,$$

if x is sufficiently small. (L.L.S.)

BINOMIAL THEOREM. Binomial Formula.

BINTURONG. Mammalia, Carnivora. An Oriental species, *Arctitis binturong,* related to the **civets.** It is cat-like in appearance with tufted ears and a long, slightly bushy tail. (A.W.L.)

BIOCENOLOGY. The division of biological science which considers the factors binding populations of animals together as units in relation to environmental conditions. A subdivision of **ecology.** (A.W.L.)

BIOCHEMISTRY. Biochemistry is that branch of the science of chemistry which deals with the chemical processes and products of living organisms. The fundamental biochemical process upon which living organisms are dependent is that of **photosynthesis** which takes place in the green leaf of the plant. Under the influence of sunlight, the green leaves of plants, through the presence of **chlorophyll**—the green coloring matter of plants—and water, fix **carbon dioxide** of the atmosphere (about 0.03% carbon dioxide of the atmosphere) into **glucose,** and ultimately into **sucrose, starches, celluloses, carboxylic acids, tannins** and **fats.** By means of **nitrogen** supplied from the soil, certain plants synthesize **proteins** (in **legumes,** cereal grains, seeds) and many other nitrogen-containing organic substances, such as the **alkaloids.** The sugars, starches, celluloses, fats and proteins are the diet of herbivorous animals. These animals serve as food producers for their own and other kinds of animals, supplying these with protein and fat in the form of **milk,** eggs, and meat. See **Foods; Carbohydrates; Fats; Aminoacids and Proteins; Photosynthesis; Vitamin.** Compounds of three carbon atoms form the common intermediary by which carbohydrates, fats and proteins are mutually interconvertible. Such three carbon compounds are lactic acid ($CH_3CHOHCOOH$), pyruvic acid ($CH_3COCOOH$), glyceric aldehyde ($CH_2OHCHOHCHO$), and pyruvic aldehyde (CH_3COCHO).

Chemical reactions of a specific character take place throughout the lifetime of each animal in each organ of its body. In the **stomach** there occurs acid digestion of foods, in the **intestines** alkaline digestion of foods, in the **lungs** absorption of oxygen into and liberation of carbon dioxide from the blood stream, in the **liver** production of glycogen and transformation of protein nitrogen into urea. The **thyroid** gland contains ten times as much iodine as any other organ of the body, and the thyroid secretion stimulates carbohydrate and calcium **metabolism** and exercises an effect on body fats. Over-secretion of the thyroid gland may result in **goiter,** whereas undersecretion may result in stunted growth or in great increase of weight from fat, accompanied by slow metabolism and retarded bone-growth.

The composition of the vegetation of the earth is estimated to consist of the four elements, **carbon, oxygen, hydrogen, nitrogen** in total amount 95%, and of the nine elements, **potassium, sodium, calcium, magnesium, silicon, sulfur, phosphorus, chlorine, iron** in total amount nearly 5%. These thirteen elements are stated above in the order of their decreasing abundance. The first three, carbon, oxygen and hydrogen, are derived from carbon dioxide of air and from water of air and soil. These, along with soluble nitrate nitrogen and the small amounts of the second group of nine elements supplied from the soil, are manufactured by the plant into its component materials, largely carbohydrates, fats and proteins. About 80 to 90% of the weight of the plant cell is water, and only in resting tissues, such as those of dried seeds, is the percentage of water small.

The composition of the human body is estimated to consist of the four elements, oxygen, carbon, hydrogen, nitrogen in total amount 96%, and of the seven elements, calcium, phosphorus, potassium, sulfur, sodium, chlorine, magnesium, in total amount about 4%. Traces of several other elements are also present in the body, **fluorine** 0.01%, **iron** 0.005%, **silicon, bromine, aluminum, manganese** about 0.001% each, and iodine still less. Small percentages of certain elements play a determining role in the functioning of certain parts of the body, e.g., iodine in the thyroid, and iron in the blood (R.K.S.)

BIOECOLOGY. The division of biological science which treats the general relations of living things. (A.W.L.)

BIOGENESIS. The established principle that all living things spring from previously existing living things. **Abiogenesis.** (A.W.L.)

BIOGENETIC LAW. Evolution.

BIOHERM. A geologic term for beds or mounds of colonial and gregarious marine **fossils** with calcareous shells or skeletons. Present day bioherms are usually referred to as **coral reefs.** (R.M.F.)

BIOLOGICAL SURVEY. A governmental agency which gathers data on the wild life of the country, makes this information available to the public through official publications, takes an active part in conservation, and aids in the control and eradication of harmful organisms.

The United States Bureau of Biological Survey was a subsidiary of the Department of Agriculture primarily occupied with work on birds and mammals. The in-

sects are dealt with by the Bureau of Entomology and Plant Quarantine and the fishes and many marine invertebrates by the Bureau of Fisheries. The work of the Bureau of Biological Survey and that of the Bureau of Fisheries was combined under the Fish and Wildlife Service of the Department of the Interior in 1940. This Service has an extensive organization reaching to all parts of the national domain and carries on the former work of the Bureau in the establishment of game refuges, the protection of game by all available measures, the extension of assistance in the propagation of game species, and the control of predatory animals.

The work of the United States Service is supplemented by that of state biological surveys. The latter, however, are limited chiefly to the study of wild life and the publication of records. Conservation activities in the states are usually in the hands of special bureaus with greater power and resources than the biological surveys. (A.W.L.)

BIONOMICS. The division of biological science which treats the relations of living things to each other and to the environment. (A.W.L.)

BIONOMY. Life habits of animals and plants. (R.M.F.)

BIOPHYSICS. The physics of biological processes or phenomena. So much has been learned in recent years as to the mechanisms of life functions that biophysics has taken its place along with **biochemistry** as an important area of material science.

Of course such matters as the dynamics of animal skeletons—with bones as levers or toggle joints—have always been cited in physics. Also the eye has long been recognized as an optical, the ear as an acoustic, instrument. More recent is the identification of nerve responses with electric currents. An extensive phase of biophysics is the role of **osmosis** in vital processes such as **secretion** and **respiration.**

Among the puzzling problems of biophysics are the phenomena of "bioluminescence," that is, the emission of light by living organisms such as the firefly and luminous fungi; and animal electricity, exhibited by such creatures as the **electric eel.**

The uses of physical techniques in medical practice are closely related to this field; such for example as the applications of **x-rays** and radioactivity to diagnosis and treatment, and the various phases of electrotherapy and **diathermy.**

Vaguely discernible on the horizon of biophysics are certain mysterious and controversial phenomena denoted as "telepathy" and "clairvoyance" While these have as yet not been divested of their associations with charlatanism, no one can say how soon they may emerge as demonstrable physical realities and take a legitimate place in biophysical science. (L.D.W.)

BIOPSY. A diagnostic procedure consisting of removal of a piece of tissue from a living patient and its examination under a microscope after sectioning and staining. This is an aid in diagnosis, especially in the differentiation of tumors, tuberculosis, and various types of chronic infections. (D.M.H.)

BIOSTROME. A geologic term for layers, beds, or strata composed of calcareous fossil shells which form **coquina,** or shell-limestone. The term biostrome is primarily intended to distinguish shell-limestone from **bioherms,** or typical coral reefs. (R.M.F.)

BIOTIC AREA. A geographical division characterized by certain environmental factors which determine the nature of its population. (A.W.L.)

BIOTIC FACTOR. Plants are profoundly affected by various environmental factors. Among these are the effects of other plants and various animals. The living forces are the biotic factors, which severally affect every part of a plant. In the soil are countless numbers of **bacteria,** including the nitrogen-fixing group, which are of tremendous importance to the plant. Here also are earthworms and various soil-inhabiting animals. Above ground are the many animals which feed on the plant and also the numerous parasites which attack it. Large numbers of these parasites gain entrance to the plant tissues, where their presence may cause very great changes. Again, there is the effect which any plant may have on its neighbors in the constant struggle for existence. Many plants are much more aggressive than others, and so able to invade new regions, where they crowd out native plants already present. Plants of this type include many of the common **weeds.** Finally a very important biotic factor is man. He is constantly disturbing the established balance by his activities, often with serious consequences to himself. Wittingly or otherwise he introduces many new plants into regions where their presence is not desirable. He cuts off forests, and so leads to the destruction of shade-loving or shade-tolerant plants which grew under the trees. Many indeed are the **fungous** pests which he has carried to new regions, where the fungus has found new hosts which had not developed resistance and so readily succumbed to the parasite. (R.M.W.)

BIOTIC POTENTIAL. A quantitative expression of the dynamic significance of various inherent vital properties of living things as a factor in the establishment of external relationships. It summarizes the reproductive and survival potentialities of the organism. (A.W.L.)

BIOTIC RESISTANCE. The living factors in the environment of an organism which tend to hinder its normal increase. Parasitic and predacious enemies and organic food supply are outstanding examples. (A.W.L.)

BIOTITE. A common **silicate** mineral containing **potassium, magnesium, iron** and **aluminum,** sometimes called "iron mica," is found in granitic rocks, **gneisses, schists,** etc. Although actually **monoclinic,** it often assumes a pseudo-**hexagonal** form. Like the others of the **mica** group biotite shows a highly perfect basal cleavage. It has a hardness of 2.5–3; specific gravity, 2.7–3.1; luster, pearly to vitreous or sometimes submetallic when very black in color; cleavage sheets are elastic; color, greenish to brown or black; transparent to opaque.

Biotite is occasionally found in large sheets, especially in **pegmatite** veins and also occurs as a contact metamorphic mineral or the product of the alteration of **hornblende, augite, wernerite** and similar minerals.

Biotite occurs in the lavas of Vesuvius, at Monzoni, and many other European localities. In the United States it is found especially in the pegmatites of New England and of Virginia and North Carolina and the granite of Pike's Peak, Colorado. Biotite was named in honor of the French physicist, J. B. Biot. (E.S.C.S.)

BIOT-SAVART LAW. A law expressing the intensity of the **magnetic field** in the neighborhood of a long, straight wire carrying a steady **current.** If a permanent **magnet** is rigidly attached in any position to a rod or frame which is capable of rotation about such a wire as an axis, it is found that there is no resultant **torque** about the wire. From this it is readily shown that the field intensity varies inversely as the distance from the wire. If the current is i (abamperes) and the distance r (cm.), the intensity is given by the Biot-Savart law as $H = 2i/r$ (oersteds). **Ampère's law** is sometimes called by this name, since either of the two laws may be deduced from the other. (L.D.W.)

BIOTYPE. A group of individuals of similar heredi tary organization. (A.W.L.)

BIPACKS AND TRIPACKS. Combinations of two or more **photographic emulsions** combined in such a way that they are all exposed together. The emulsions may be on separate supports in which case they are called separable bipacks and tripacks, or the emulsion may be coated on a single support when they are called integral bipacks and tripacks.

The simplest bipack consists of two emulsions on separate supports placed in the film or plate holder with the emulsions held together in intimate contact. Such a separable bipack has found wide application in making 2- and 3-color **motion pictures** and as a means of obtaining two of the necessary three color separation negatives in a 3-color camera. Bipacks may also be obtained by coating two photographic emulsions on opposite sides of a single support (two-sided bipack) or two emulsions coated on the same side of a single support (integral bipack). The type of bipack construction is generally dictated by the method of color image formation to be employed in the process concerned.

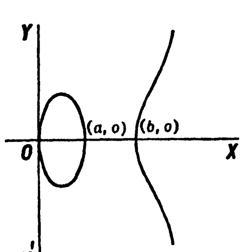
Tripacks may contain three separate emulsions on different supports (separable tripack) or three emulsions on two supports using an integral bipack on one and the other emulsion on a separate support. The most common tripacks today are integral and use but one support to carry all three emulsions. There may be an integral bipack on one side and the third emulsion on the other side (two-sided integral bipack) or all three emulsions may be on one side of the support (monopack)

The **photographic emulsions** employed in integral bipacks and tripacks are generally quite thin (.005–.02 mm.) and transparent to prevent too great light absorption in the upper emulsions and consequent loss of speed and diffusion. In the usual construction for a 3-color system the red sensitive emulsion is nearest the support with the blue recording layer being on the top surface. The top blue sensitive emulsion is generally separated from the green and red recording emulsions by a yellow separating layer to prevent any blue light from being recorded by these emulsions.

Integral bipacks and tripacks are now widely used as camera materials for taking pictures which are converted into color images by means of dye coupling development or **chemical dye destruction.** Integral tripacks are also used as a means of obtaining three-color prints by the same photographic processes. Present trends indicate a gradual replacement of most systems of **color photography** in which separate images are converted into the subtractive colorants by systems making use of the advantages of integral tripacks. (H.C.C.)

BIPARTITE CUBIC. This name is given to the curve whose equation in **rectangular coordinates** is

$$y^2 = x(x - a)(x - b) \quad (0 < a < b).$$



Bipartite cubic.

Its shape is shown by the accompanying figure. (L.L.S.)

BIPINNARIA. The form of **dipleurula** larva found in the starfishes (**Asteroidea**). It is bilaterally symmetrical and has a ciliated band. (A.W.L.)

BIPLANE, EFFICIENCY OF. Equivalent Monoplane.

BIPRISM. Young's Interference Experiment.

BIQUADRATIC EQUATIONS. Quartic Equations.

BIRAMOUS APPENDAGE. The primitive jointed appendage of the **arthropods,** still found in various form in the **crustaceans.**

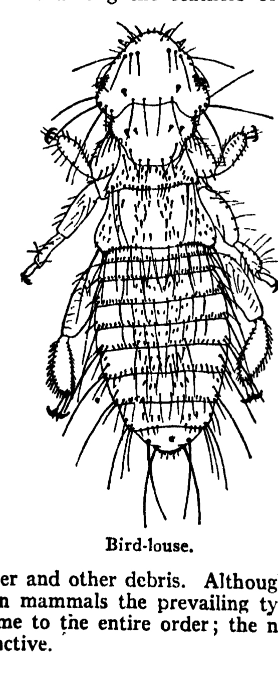
The appendage consists of a single basal portion called the protopodite which is usually divided into a proximal coxopodite and a distal basipodite. It may bear on its outer margin one or several lobes called epipodites. From the protopodite two branches arise, an inner endopodite and an outer exopodite; this characteristic of the appendage is responsible for the name biramous. The endopodite is divided into five or less segments, named in order from the base the ischiopodite, meropodite, carpopodite, propodite, and dactylopodite. The exopodite is much less uniform and is often lacking.

These appendages have become modified and specialized for many functions in the existing crustaceans, as is nicely demonstrated by the appendages of the **crayfish** and **lobster.** In these animals they form sensory organs (antennae), mouth parts (jaws and accessory appendages), walking legs, swimmerets, accessory reproductive organs, and broad, flat swimming appendages. They are also regarded as the form from which the simpler jointed appendages of insects and other arthropods have been evolved. (A.W.L.)

BIRD. A warm-blooded feathered vertebrate. (See **Aves.**) (A.W.L.)

BIRD OF PARADISE. Aves, Passeriformes. Any bird (**Aves**) of numerous beautiful species which make up the family Paradiseidae. They are characterized by the gorgeous colors and bizarre forms of the plumage and are unsurpassed in splendor by any other group of birds, although they are fairly near to the crows in classification. Most of the species are found in New Guinea. (A.W.L.)

BIRD-LOUSE. Insecta, Mallophaga. A wingless ectoparasitic insect with biting mouth parts. Most species of bird lice live among the feathers of birds and eat



Bird-louse.

bits of feather and other debris. Although a few species are found on mammals the prevailing type of host has given its name to the entire order; the name biting lice is also distinctive.

The bird-lice which affect poultry are economically important. Even though they do not suck blood like other parasites the irritation resulting from their presence in large numbers is serious to the birds. Various measures of control have been devised, among them whitewashing roosts, oiling perches with kerosene, and the use of various insect powders in nests and on the birds themselves. The maintenance of clean surroundings for the flock is of the utmost importance in preventing severe infestation. (A.W.L.)

BIRD'S-NEST FUNGI. **Basidiomycetes.**

BIRMINGHAM WIRE GAUGE. **Gauge Number.**

BISHOP-BIRD. Aves, Passeriformes. Any bird (**Aves**) of several brightly colored species of African weaver-birds which make up the genus *Pyromelana*. The name has also been applied in the past to some of the brightly colored birds of North America, especially by the early settlers in Louisiana. (A.W.L.)

BISMITE. **Stibiconite.**

BISMUTH. Symbol: Bi. Atomic number: 83. Atomic weight: 209.00. Density: 9.8. Hardness: 2.5. Melting point: 271° C. Boiling point: 1450° C. No isotope, but of single atomic form: 209.

Bismuth is a white metal having a reddish tinge, lustrous, brittle, not very hard, somewhat malleable, not very ductile, when bent at 100° C. emits a creaking sound due to friction of the crystals; permanent in air or ordinary temperatures, burns to the trioxide upon heating to high temperature; insoluble in **hydrochloric** or dilute **sulfuric acid**, soluble in **nitric acid** to form nitrate; heated with **chlorine** yields chloride. Discovered by Valentine in 1450. Bismuth metal is used in alloys, for bearing or anti-friction metals, and for fusible metals. The salts of bismuth are frequently used in medicine, principally in (1) digestive disorders as a soothing protective to irritated mucous membranes, (2) in **x-ray** diagnostic examination where the opacity of bismuth makes simple the production of contrast pictures of the entire gastro-intestinal tract, (3) in the treatment of **syphilis** where it is given intramuscularly by hypodermic injection.

Bismuth occurs as native bismuth in Bolivia and Saxony and frequently is associated with lead, copper, and tin ores—the sulfide (**bismuthinite**, bismuth glance, Bi_2S_3) is also found in nature. Separation of bismuth from lead takes place during the **electrolytic** refining of the latter with bismuth remaining in the anode mud.

Chlorides: Bismuth chloride ($BiCl_3$), white crystals by reaction of (1) bismuth metal heated with **chlorine**, (2) bismuth oxide and **hydrochloric acid**, and then crystallizing, reactive with water to form oxychloride; bismuth oxychloride, bismuth subchloride ($BiOCl$), white solid, soluble in hydrochloric acid.

Hydroxide: Bismuth hydroxide ($Bi(OH)_3$), white precipitate, by reaction of bismuth salt solutions and alkalis, soluble in hydrochloric, sulfuric, or nitric acid.

Nitrates: Bismuth nitrate ($Bi(NO_3)_3 \cdot 5H_2O$), white crystals, by reaction of (1) bismuth metal or oxide and **nitric acid**, and then crystallizing, reactive with water to form oxynitrate; bismuth oxynitrate, bismuth subnitrate ($BiONO_3$), white solid, soluble in nitric acid, used in cosmetics, in pharmacy, in producing luster on metals, in enamels on ceramic ware.

Oxides: Bismuth oxide, bismuth trioxide (Bi_2O_3), pale yellow to brownish solid (1) by heating bismuth hydroxide or nitrate, (2) by burning bismuth at a high temperature in air, soluble in hydrochloric, sulfuric, or nitric acid; bismuth textroxide (Bi_2O_4), yellow to brown solid by reaction of bismuth trioxide and sodium hypochlorite solution; bismuth pentoxide (probably $Bi_2O_5 \cdot H_2O$ or $HBiO_3$), scarlet red, by electrolytic oxidation of bismuth trioxide in alkali, decomposes when heated at 150° C. yielding trioxide and oxygen.

Sodium bismuthate ($NaBiO_3$) is used in acid to oxidize manganous to permanganate in the identification of manganese.

Sulfates: Bismuth sulfate ($Bi_2(SO_4)_3$), white crystals, by reaction of bismuth trioxide and sulfuric acid, and then crystallizing, reactive with water to form bismuth oxysulfate; bismuth oxysulfate, bismuth subsulfate ($(BiO)_2SO_4$), white solid, soluble in sulfuric acid.

Sulfide: Bismuth sulfide (Bi_2S_3), dark brown precipitate, by reaction of bismuth salt solution and **hydrogen sulfide**, soluble in hot dilute nitric acid, insoluble in **sodium** or **ammonium** sulfide. (R.K.S.)

REPRESENTATIVE ALLOYS CONTAINING BISMUTH

Fusible alloy, melting at 96° C.	53% Bi	32% Pb	15% Sm
Fusible alloy, melting at 91.5° C.	52% Bi	40% Pb	8% Cd
Fusible alloy, melting at 100° C.	50% Bi	30% Sn	20% Pb
Fusible alloy, melting at 70° C. (Wood's metal).	50% Bi	25% Pb	12.5% Sn 12.5% Cd
Fusible alloy, melting at 70° C. (Lipowitz' alloy)	50% Bi	27% Pb	13% Sn 10% Cd
Rose metal	50% Bi	27% Pb	23% Sn
Bismuth solder, melting at 111° C.	40% Bi	40% Pb	20% Sn

(R.K.S

BISMUTHINITE (Bismuth Glance). A mineral containing a **sulfide** of **bismuth** and sometimes **copper** and **iron**; a variety from Mexico contains about 8% **antimony**. Bismuthinite is **orthorhombic** although its thin needlelike crystals are rare as it usually occurs in foliated or fibrous masses. It has one good cleavage parallel to the prism; hardness, 2; specific gravity, 6.4–6.5; metallic luster; streak, lead gray; color, similar but often with iridescent tarnish; opaque.

Bismuthinite is a rather rare mineral although somewhat widely distributed. European localities are in Norway, Sweden, Saxony, Rumania, and England. It is found also in Bolivia, Australia, and in the United States in Utah. It is used as an ore of bismuth. (E.S.C.S.)

BISON. Mammalia, Artiodactyla. A large hoofed animal with a prominent hump, short curved horns, and in the male sex a heavy mane. Two species occur, the European, *Bison bonasus*, and American, *B. americanus*. The former is a browsing forest species of northern Europe and the latter a grazing species, formerly very abundant on the plains of North America but now restricted to a few protected herds.

The romantic—and tragic—story of the American bison is known to everyone. A mainstay of the Plains Indians for food, hides for the construction of shelters, and fuel in the form of buffalo chips, it served the same purposes for early settlers, but the greater destructiveness of firearms and the availability of an Eastern market for hides soon threatened its extinction. A herd of about 6000 is now maintained in the Yellowstone National Park and a much larger number in Canada.

The European bison also goes by the names wisent and zubr but the name aurochs, sometimes applied to it, is not correctly used here. (A.W.L.)

BIT. **Woodworking.**

BITING LOUSE. **Bird-Louse.**

BITTERLING. Pisces, Teleostei. Fishes (**Pisces**) of several species allied to the carp. One, *Rhodeus amarus*, lives in Europe and the others in Eastern Asia. (A.W.L.)

BITTERN. Aves, Ciconiiformes. Wading birds (**Aves**) allied to the herons and egrets. They have moderately long legs and a straight beak which is strong and sharp. Two species, the American, *Botaurus lentiginosus*, and least, *Ixobrychus exilis*, bitterns, occur in North America, and several others are found on other continents. (A.W.L.)

BITUMEN. A general term for petroliferous substances ranging from true **petroleum** through the so-called mineral tars to **asphalt.** (R.M.F.)

BITUMINOUS COAL. Coal.

BIURET. Amines and Amides.

BIVALVE. A shell composed of two distinct parts or valves. Such shells are secreted by **brachiopods**, in which the valves are dorsal and ventral, and by certain **crustaceans** (Ostracoda) and **mollusks** (Pelecypoda) in which the valves are lateral. The most common examples of bivalves are among the edible mollusks, including **clams, oysters,** and **scallops.** (A.W.L.)

BLACK APE. Mammalia, Primates. A **monkey**, *Cynopithecus niger*, of Celebes whose rudimentary tail gives it some superficial likeness to the apes. It has an elongate muzzle and is related to the **macaques** and **baboons.** (A.W.L.)

BLACK BODY. This term denotes an ideal body which would, if it existed, absorb all and reflect none of the **radiation** falling upon it; its reflectivity would be zero and its absorptivity would be 100%. Such a body would, when illuminated, appear perfectly black, and would be invisible except as its outline might be revealed by the obscuring of objects beyond. The chief interest attached to such a body lies in the character of the radiation emitted by it when heated and the laws which govern the relations of the **flux** density and the **spectral energy distribution** of that radiation to the temperature.

The total emission of radiant energy from a black body takes place at a rate expressed by the **Stefan-Boltzmann** (fourth-power) **law**; while its spectral energy distribution is described by **Wien's laws,** or more accurately by **Planck's equation,** as well as by a number of other empirical laws and formulae. (See **Thermal Radiation.**)

The nearest approach to the ideal black body, experimentally, is not a sooty surface, as might be supposed, but an almost completely closed cavity in an opaque body, such as a jug. The laboratory type is usually a somewhat elongated, hollow metal cylinder, blackened inside, and completely closed except for a narrow slit in one end. When such an enclosure (called a *Hohlraum* in German) is heated, the radiation escaping through the opening closely resembles the ideal black-body radiation; while light or other radiation entering by the opening is almost completely trapped by multiple reflection from the walls, so that the opening usually appears intensely black. For this reason, black-body or "Planckian" radiation is also often called "cavity radiation." (L.D.W.)

BLACK BUCK. Mammalia, Artiodactyla. The Indian **antelope**, *Antilope cervicapra.* (A.W.L.)

BLACK COLOB. Mammalia, Primates. A species of thumbless **monkey**, *Colobus satanus,* found in western Africa. (A.W.L.)

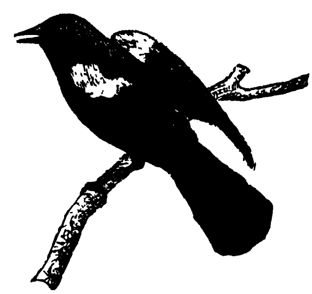
BLACK DEATH. The great pandemic of **plague** which swept Europe in 1348. (D.M.H.)

BLACK PRINTER. A separate image used in the making of a color reproduction by subtractive synthesis. The black printer is often necessary because of the difficulty of reproducing grays and black from mixtures of the colorants used in making the color reproduction and also to impart sufficient density to the dark portions of the reproduction.

A negative for making the black printer may be made by using a yellow filter with a panchromatic emulsion or by using an infra-red emulsion and filter transmitting only infra-red light. Most photomechanical methods of color reproduction use a black printer and some photographic procedures, such as imbibition, occasionally make use of such an achromatic image. (H.C.C.)

BLACKBERRY. Rose Family.

BLACKBIRD. Aves, Passeriformes. 1. The ouzel of Europe. 2. Several species of North American birds of the genus *Agelaius* related to the orioles and grackles,



A North American red-winged blackbird. Glossy black, shoulders scarlet, edged with yellowish. Female streaked with no red.

and sometimes applied to the grackles as well. 3. In the West Indies applied to the ani, a member of the order Cuculiformes. (A.W.L.)

BLACKCOCK. Aves, Galliformes. The male of the Eurasian black **grouse**, *Lyrurus,* of which there are two species, one limited to the Caucasus. (A.W.L.)

BLACKFIN. Pisces, Teleostei. A small fish (**Pisces**), *Lythrurus atripes,* of southern Illinois and Iowa with black-marked dorsal and anal fins. Related to the shiners. (A.W.L.)

BLACKFISH. 1. Pisces, Teleostei. The black sea **bass,** *Centropristis striatus.* 2. Mammalia, Odontoceti. A black **whale** of moderate size, up to 20′ long. It is found in both the Atlantic and Pacific Oceans and is widely distributed from north to south. Also called the pilot whale, *Globicephalus melas.* (A.W.L.)

BLACK-FLY. Insecta, Diptera. A minute fly whose small head and large **thorax** give it a hump-backed appearance. They are also called buffalo-gnats and the Indian name no-see-'em is sometimes used for the very small species. They constitute the family Simuliidae.

While some of these insects are harmless, others are among the most troublesome of our blood-sucking insects. Their bite is extremely irritating, considering its size, and the swarms are sometimes so numerous that their attack is serious to man and may cause the death of smaller animals, such as chicks. They are especially abundant in the woods, where campers and outdoor workers sometimes find it necessary to use oil of citronella, or one of the preparations containing tar, on exposed portions of the skin to prevent attack. (A.W.L.)

BLACK-GAME. Aves., Galliformes. The Eurasian black **grouse.** (A.W.L.)

BLACKHORSE. Pisces, Teleostei. A fish (**Pisces**) *Cycleptus elongatus,* of the Mississippi River system, also called the Missouri sucker. It attains a length of thirty inches and its flesh is excellent. (A.W.L.)

BLACKWATER FEVER. Malaria.

BLADDER. A thin-walled muscular sac which serves as a reservoir for urine. It is situated in the anterior portion of the pelvic cavity. The urine drains from the kidneys down the ureters, and the latter enter the bladder one on either side. The mucous-membrane linings of the kidneys, ureters and bladder are continuous.

The term bladder is also used to describe similar sacs such as the **gall bladder** and the swim bladder of fishes. (D.M.H., A.W.L.)

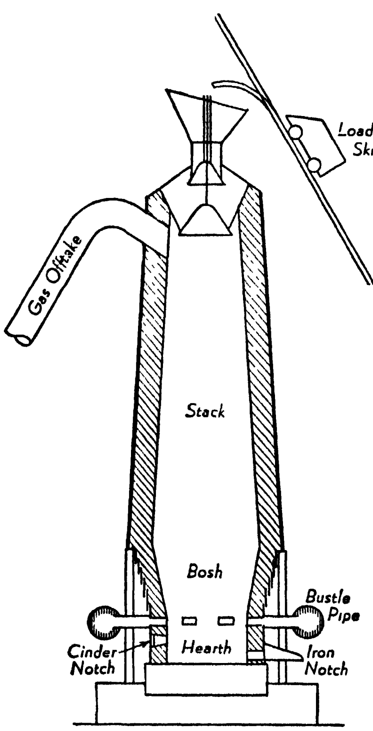
BLADDER WORM. Platyhelminthes, Cestoda. An immature resting stage of **tapeworms** consisting of a bladder-like **cyst** in which one or more heads are inverted. Also known as the cysticercus stage. (A.W.L.)

BLADDERWORTS. Insectivorous Plants.

BLADE. Leaf.

BLANK. Sheet Metal Processes; Press-working.

BLAST FURNACE. The blast furnace is the chief means of reducing iron ore to pig iron. The reduction process is carried out at high temperature, and in the presence of a fluxing substance. A cross-section of a blast furnace is shown in the accompanying figure. The



Blast furnace.

furnace may be 90–100′ high, and of varying diameters. It may be thought of as being composed of three sections: the lower section, called the hearth, in which the molten iron is accumulated; a short section above the hearth, called the bosh; and the stack, which is above the bosh. The hearth portion is constructed of fire-brick of the best quality with thick walls. The tapping hole is situated at some convenient point in the hearth, as is also the slag hole. Near the top of the hearth section tuyères are spaced around the circumference for the admission of air for combustion. Each tuyère receives a supply of air from the tuyère stock which is connected to a header called a bustle pipe. The latter is a large pipe which encircles the furnace and distributes heated air to the tuyères. The bosh, being just above the air admission point, encloses the hottest portion of the furnace. In order to keep the bricks from burning out, water-cooled plates are built into the brickwork of the bosh, and much heat is carried away by the circulating water. Extending upward from the bosh to the top of the furnace is the stack, made of plate steel and lined with fire-brick. At the top of the furnace is a double bell, which forms a sort of air lock for the admission of materials during continuous operation of the furnace.

When in use, the blast furnace is first charged in the proper manner with alternate layers of **coke,** ore, and **limestone.** The coke is ignited at the bottom and is rapidly burned under the influence of a forced draft of air blown in through the tuyères. As the coke is burned away, the material moves downward in the furnace towards the hearth, but the stack is kept full by fresh charges admitted through the bells. The process of reduction is rather complicated chemically, but the net effect is the conversion of the ore, which may consist chiefly of **hematite** (Fe_2O_3), into liquid iron in the hearth, with slag, consisting of the limestone flux and the ash from the coke, together with compounds formed by reaction of the flux with substances present in the ore, floating in a molten state on the iron. This molten slag, or cinder, may be tapped off through the cinder notch, which is a slag opening. The iron is tapped at intervals through the iron notch. As the hot gases from the combustion region pass upward from the furnace they heat the fresh charges and pass out of the furnace through ducts which carry them to the purifying equipment. Since a reducing atmosphere is maintained in the blast furnace, the gases leaving it have some fuel value, due to their **carbon monoxide** content. These gases are passed through dust catchers and scrubbers until they are comparatively free from dust, after which part of the gas is used in gas engines which operate the blowers, and part of it is used in stoves or regenerative heaters, which preheat the air going to the bustle pipe. (F.T.M.)

BLASTING. Blasting is the rending or loosening of a hard or closely packed material by **explosives.** Blasting action can be one of shattering percussion or heaving, depending upon the type of explosive used, and the method by which it is placed. The principal field of blasting is in connection with earth or rock, although many other uses are found for it. For example, it may be used to loosen coal from the seam, to fell a large obsolete chimney, or to break up foundations which are to be replaced, etc. Blasting is very frequently used in preparing the right of way for a new road. Rocks must be shattered, boulders loosened and broken up, tree stumps blown out, and earth loosened and rendered suitable for rapid excavation. Quarry work offers a considerable opportunity for skilful removal of stone from the native mass by means of judiciously placed explosives. Ditches may be dug with explosives by transmitted blasting, and material of all sorts may be loosened so that loading by power shovel is rapid and economical.

The explosives used for blasting constitute one very definite branch of all explosives. Dynamite and powder are chiefly used. While a great many high-powered explosives of different sorts are used in shells for offensive weapons, these are not suitable for general

blasting service. Nitroglycerin dynamite and ammonia dynamite are the principal explosives for commercial blasting work. Blasting powders are also used where a permissible explosive is not required. A permissible explosive is a short-flame explosive which is considered safe for use in mines where the atmosphere may contain some combustible gas. This feature is not important, naturally, for blasting in stone, slate, and granite quarries, where blasting powder is in use. Dynamite is available in cartridges, in granular form, and powder form Some dynamite, such as gelatin dynamite, is distinguished by plasticity, high density, and imperviousness to water. Other dynamites cannot be used in wet locations. In cold weather special low freezing formulae are required. The dynamite cartridges are made in strength varying from 15–60% dynamite so that the explosive power of a blast may be regulated. Dynamite and blasting powder are set off by means of blasting caps containing picric acid, tetryl and mercury fulminate, or lead azide. The blasting caps are ignited to produce an initial detonation, either by the heat of a fuse or by an electric current. A blasting machine is a hand-operated apparatus for generating current used in firing electric blasting caps.

There are several ways of using an explosive in blasting. A hole may be drilled in the earth or rock, and the dynamite cartridges placed at the bottom of the hole. The blasting cap, with fuse or wires attached, is placed on the top of the charge, and the hole is then "stemmed." Stemming consists of carefully tamping the hole above the explosive full of a material such as moist clay or earth, so that the explosive force of the dynamite will be confined and will produce the maximum shattering or loosening effect. Another way of using dynamite is to place it on top of the boulder or rock to be shattered, and cap it thoroughly with a layer of mud or clay well packed. The effectiveness of this kind of blasting is the result of the intensely fast action of dynamite, so rapid that the mud and atmospheric reactions are sufficient to give a shattering blow to rock or boulders having a brittle structure. This method of blasting tends to be wasteful of explosive, and is not used unless other methods, such as boring of holes, are impracticable. A blast of this character is known as a "dobie" shot. Considerable skill in the use of multiple charges in excavation or break-up of rock or coal is attained by those dealing regularly with dynamite. There are two methods of detonating multiple charges. With one, the charges are exploded simultaneously; with the other, one charge explodes the next one, and so on. For simultaneous explosion, electrical firing is a necessity, but where electrical firing is not used, multiple charges can be set off without difficulty if the ground is so thoroughly wet that the shock of an initial charge is transmitted through the ground to the adjacent one with sufficient intensity to detonate it. Blasting is comparatively safe in the hands of those trained and skilled in the use of explosives as long as they remain careful and cognizant of the hazards involved, but is not to be recommended for the inexperienced or casual user of explosives. (F.T.M.)

BLASTOCOELE. The first cavity formed during the **embryonic** development of animals. In many species the cleavage of the fertilized **ovum** gives rise to a hollow **blastula** of spheroidal form; the cavity of this structure is the blastocoele. (A.W.L.)

BLASTOMERE. Any of the **cells** resulting from the subdivision of the fertilized **ovum** during early embryonic development. (A.W.L.)

BLASTOMYCOSIS. A chronic infection caused by **fungi** of the blastomycetes group. It is characterized by multiple abscesses in the skin and at times of the internal organs. The disease is not common but more cases are seen in the Middle West than elsewhere in the United States. Blastomycosis is chronic and prolonged with remissions. The systemic form is usually fatal. (R.S.M., D.M.H.)

BLASTOPORE. The external opening of the **gastrula.** (A.W.L.)

BLASTOSTYLE. A **polyp** from which medusae arise by budding in colonies of hydrozoan **coelenterates.** (A.W.L.)

BLASTULA. The stage in embryonic development which results from cleavage of the fertilized **ovum** and precedes the establishment of the germ layers. It is a hollow sphere in its primitive form but is modified in many animals, particularly in connection with the extensive storage of yolk in the egg, and in some of these modified forms the exact equivalent of the primitive blastula is difficult to determine. (A.W.L.)

BLAUBOK. Mammalia, Artiodactyla. *Hippotragus.* A South African **antelope** allied to the oryxes. It is said to be extinct. (A.W.L.)

BLEACHING SUBSTANCES, BLEACHING AND DECOLORIZING. Bleaching and decolorizing treatments are applied to **textile** fibers, **paper** pulp, **wheat** flour, **petroleum** products, **oils** and **fats,** raw **sugar** solutions. In some cases, the results are attained by chemical reaction of the reagent and material treated, and in other cases by absorption of undesirable material by the reagent followed by separation, e.g., by filtration, from the desired material.

The following gases are used in bleaching flour· **chlorine** 300 parts per million, chlorine (98%) plus nitrosyl chloride (2%) 300 parts per million, **nitrogen** tetroxide 4 parts per million, **nitrogen** trichloride 50 parts per million, and most commonly, **benzoyl peroxide** 120 parts per million.

Chlorine, sodium **hypochlorite** and calcium hypochlorite are strongly oxidizing in their behavior, **hydrogen peroxide** and per- compounds mildly oxidizing, and **sulfur dioxide** reducing. Hydrogen peroxide is specially adapted for use in bleaching hair, silk, feathers, straw, ivory, teeth, bones, gelatin. Chlorine and hypochlorites are used in bleaching paper pulp, and sodium peroxide for bleaching mechanical wood pulp.

Chlorine and hypochlorites, when used in bleaching textile fibers and paper pulp, must be scrupulously removed upon completion of the bleaching operation to avoid deterioration by further action. This is done by the use of antichlor, such as **sodium** thiosulfate solution.

Various porous solids of high adsorptive power are used for decolorizing liquids and solutions. (See **Colloidal state, Adsorption.**) Bone charcoal is used to decolorize raw sugar solutions, various clays and gels for oils and fats. (R.K.S.)

BLEAK. Pisces, Teleostei. *Alburnus.* Small fishes **(Pisces)** of several species found in Europe and western Asia, related to the **carps.** (A.W.L.)

BLEEDER. In medicine a bleeder is an individual whose blood does not clot normally. (See **Hemophilia** and **Heredity.**) (R.S.M.)

BLEEDER RESISTANCE. A permanently connected resistor across the output of a **power supply.** (L.R.Q.)

BLEEDER TURBINE. Steam Turbine.

BLEEDING IN PLANTS. Often, particularly in spring, sap may be observed flowing from the broken

ends of branches, from the fresh stumps left when stems are cut, or from cracks. The phenomenon is called "bleeding." The force causing this flow of sap from stems is called root pressure, since it seems due to osmotic forces in the living cells of the root. The flow of maple sap when the tree is tapped in the spring may be considered as a form of "bleeding." (See **Ascent of Sap.**) (R.M.W.)

BLENDE. Sphalerite.

BLENNY. Pisces, Teleostei. Marine and fresh-water fishes (**Pisces**) of wide distribution. Some move about on the bottom by means of the paired fins and others are able to leave the water and move about on the shore. About 50 species of blennies are known. (A.W.L.)

BLEPHAROPLAST. The basal body from which a **cilium** or **flagellum** grows forth. In many cases synonymous with **centrosome.** (A.W.L.)

BLESSBOK. Mammalia, Artiodactyla. One of the smaller species of South African **antelopes,** *Damaliscus albifrons.* (A.W.L.)

BLIND FLIGHT. Ordinarily, piloting of aircraft is accomplished by visual orientation on the part of the pilot with respect to fixed references such as horizon, clouds, and sky. Although some experimentation has been made with flying instruction starting with the hooded cockpit, this is still in its infancy, and piloting talent of the present time has been built up on the basis of visual orientation. Now when the aforementioned references are blotted out from view by fog, clouds, snow, or rain, the pilot cannot, by sense of gravity alone, maintain even keel and constant heading of the aircraft. Under these circumstances he is faced with the necessity of blind flight, that is maintenance of direction and equilibrium by the use of instruments located in the cockpit, which are read by the pilot, and used by him to create a mental image of the attitude of his plane.

When blind flight becomes necessary the only alternatives are to quit the airplane by parachute, or risk a crash. The ordinary flight instruments are not sufficient for blind instrument flight because of errors they introduce when the airplane undergoes circling flight. The ordinary bubble or bank indicator, pitch indicator, and compass may be sufficient for short stretches of blind flight if the air is comparatively calm, but are not to be thought of as blind flying instruments. In this classification come the artificial horizon, the turn and bank indicator, the sensitive altimeter, and various radio apparatus. The gyroscope possesses features which fit it admirably for incorporation into various types of flight instruments, particularly those which indicate the flight condition of the airplane. The artificial horizon, for instance, has a vertical gyroscopic axis in a frame mounted on gimbals so that it can rotate freely in the casing. The case is fixed to the airplane, and should the latter move out of the desired flight conditions, a small visible bar maintains a true horizontal position. A small painted airplane on the dial moves with the frame and the airplane, and its position with respect to the true horizontal bar gives the pilot an easily assimilated image of the position of the real plane with respect to the actual horizon. Thus he may instantly apply corrective measures to offset **rolls** or **pitches** caused by air conditions.

Since, in blind flight, the lack of sight of the ground prevents the visual observation of drift or other methods of determining the effects of wind, the radio must be depended on for the maintenance of the airplane on a course which is being flown blind. While meteorological information may be given by radio, a radio system designed for the specific purpose of indicating a given course has been devised and put into operation in the United States by the Civil Aeronautics Administration. This is known as the **radio range,** and forms the important element of the Federal airways.

The radio beacon sends out signals directively along predetermined courses coinciding with the established airways. Each radio range beacon provides four courses. The standard offcourse signals of dash-dot and dot-dash are transmitted in groups separated by the station identifying signal. "On-course" is indicated by the interlocking of "off-course" signals, thus forming a series of long dashes or continuous monotone signals which are also separated by the station signal. The sending antenna consists of two loops at an angle to each other. The signals sent out by these antennae form a pattern in a horizontal plane, whereby the course may be determined. It will be noted that though there are apparently four courses, the inclination of the sending loops is set to produce a narrow beam on the desired course leaving that at right angles too wide to be of much use. Reliable reception on aircraft in flight can normally be had up to distances approximately 100 miles from the station, and the width of the beam in which the dot-dash and dash-dot signals are completely interlocked is about 10 miles at a point 100 miles from the station. As long as the pilot is on course, he hears in the earphones a series of long dashes interspersed with a range beacon identifying signal. Should the plane get off to one side of the marked course, the dashes would gradually break up and be replaced by the off-course signal, either a dot-dash, or a dash-dot, depending on which side of the true course the deviation had been made. (F.T.M.)

BLIND LANDING. Radio has proven the means of overcoming many of the difficulties of flying under adverse conditions, and present developments indicate that it will soon bring the solution to the most difficult of all flying problems, that of landing an airplane when visibility is reduced to zero. For aircraft to become a safe and reliable means of transportation under all weather conditions it must be possible to land the plane safely when fog prevents the pilot seeing the landing strip from even the lowest altitude. Blind-landing or, more accurately, instrument-landing equipment has been under development for several years and several systems have been devised. However, the more successful ones differ more in the details than in the essentials of the system.

A system for making an instrument landing must provide the pilot with an accurate indication of his location with respect to the runway in three dimensions—laterally, vertically and longitudinally. This information is transmitted by means of a so-called localizer beam, two position fixes provided by "marker beacons" and a glide-path beam. While not the only system, the following one, developed under the sponsorship of the Civil Aeronautics Authority (later the Civil Aeronautics Administration) will indicate the general problem and how it may be solved.

The ground equipment calls for four **transmitters** for each landing direction while the plane equipment consists of three **receivers,** associated circuits and indicating instruments. The localizer beam, which lines the incoming plane up with the runway, is very similar to the **radio range** used to guide aircraft cross-country. A very high frequency transmitter produces two overlapping field patterns by means of directive antennae. (See **Directional Antenna.**) One of these patterns is modulated at 150 cycles and the other at 90 cycles. The course is indicated by the line where the overlapping patterns produce equal intensities. The glide path, which determines the path of the incoming plane in the vertical direction, is provided by another very high frequency (but frequency different from the localizer) transmitter producing a directional field pattern. This signal is modulated with 60 cycles. The glide path is a path in this field which gives constant signal strength

at the airplane receiver. In order to get the exact sort of path desired the transmitter is located to one side of the runway and the beam is directed over it at an angle. This path is practically a straight line as the plane starts down and then becomes parabolic and meets the runway tangentially. Two marker beacon transmitters (fan markers), modulated with different frequencies are located at known distances from the end of the runway. These transmitters radiate relatively thin fan-shaped fields upward so they indicate well defined locations to an airplane flying through them. Fig. *1a* shows the general location of the various transmitters and *1b* shows the profile of the glide-path and marker patterns. The plane carries three receivers to pick up

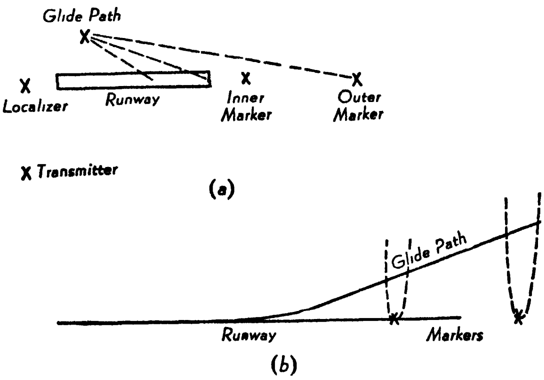


Fig. 1. Blind landing.

the signals radiated at three different frequencies by the ground stations, i.e., the localizer signals, the glide-path signals and the marker signals. Several types of instruments have been developed to combine these various signals so a single instrument indicates all the pilot needs to land the plane. In the so-called cross-pointer instrument the marker beacons cause colored lights to operate when the plane passes through their field, the localizer signals actuate a needle which is centered vertically for on-course and deflects to the appropriate side when the airplane gets off the course, and the glide-path receiver output actuates a horizontal needle which deflects up or down if the plane is not on the glide path. Thus when the plane is coming in along the correct path the two needles cross in the center of the instrument and the lights indicate two known points along this path. Other instruments give the same indications by means of spots or lines on the screen of a cathode ray tube.

Reference to Fig. 2 will show the path of a plane making an instrument landing by this system. As the

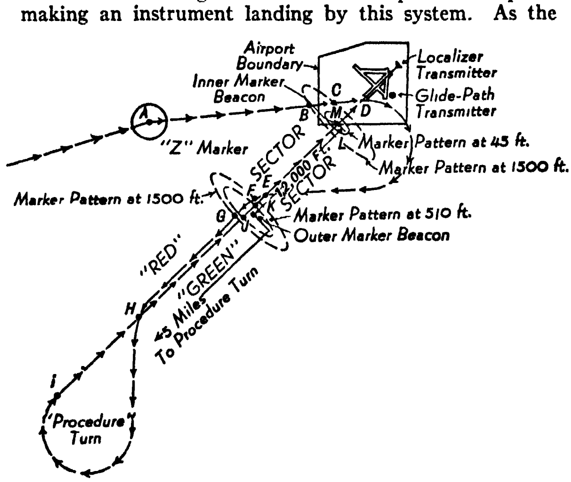

Fig. 2. Landing path. (*From Electrical Engineering, December 1940, p. 496.*)

pilot approaches the airport he first gets a fix by the marker at *A*, then flies at an altitude of 1500′ directly towards the airport, cutting the field of the inner marker beacon. The appropriate light on his instrument lights while he is in the field, giving an indication of his angle with respect to the fan field. This instrument also indicates which side of the localizer beam he is on and he makes a turn to align himself with the localizer beam. He crosses the outer marker and continues to fly the beam for 5 miles and then makes a turn to begin the landing run. By keeping the plane on the localizer and glide-path beams as indicated by his landing instrument he passes through the marker fields again, the outer one at 500′ and the inner one at 45′. Within a short interval after passing the inner marker contact is made with the runway. (L.R.Q.)

BLIND SPOT. That portion of the **retina** of the eye where the optic nerve enters; it is insensitive to light. (D.M.H.)

BLIND WORM. Amphibia, Gymnophiona. Slender worm-like **amphibians** with no trace of legs and with the tail and eyes rudimentary. They are also called caecilians. (A.W.L.)

BLIND-FISH. Pisces. Teleostei. Small fishes (**Pisces**) of which certain cave-inhabiting species have rudimentary eyes. Together with a few species whose eyes are normal they make up the family Amblyopsidae. (A.W.L.)

BLISTER BEETLE. Insecta, Coleoptera. Soft-bodied **beetles** of medium to large size. They are named from their blistering properties; when crushed on the skin even the common species are capable of raising a blister.

Blister beetles are of commercial importance as a source of a pharmaceutical preparation known as Spanish-fly, from the species of that name. This material is composed of the dried pulverized bodies of the insects and is used for producing blisters. Some of the North American species are also occasionally important enemies of plants, among them the old-fashioned potato beetle. They can be checked by the application of sprays containing arsenical poisons.

Several hundred species of blister beetles have been described. They constitute the family Meloidae. (A.W.L.)

BLIZZARD. Wind storms accompanied by low temperatures and blowing or falling snow. (P.E.K.)

BLOCK CHAIN. Chain.

BLOCK SIGNAL. A block signal is the mechanism employed to show the engineman, operating a train over a railroad protected by the automatic block signal system, whether there are any trains in the block ahead. In the operation of a railroad system the trackage is divided into blocks of from 1–5 miles' length, and the **railway signalling** system devised to prevent two trains occupying the block simultaneously. The block signal itself is a semaphore mounted on a mast and placed alongside the track in clear view of the enginemen. It is electrically energized from an a-c or d-c transmission line running along the right of way, and is actuated by electromagnets properly connected across the "blocks" of track. A standard system of signalling is the semaphore arm held vertical for "proceed" and horizontal for "stop." At night, red and green lights supplement the semaphore as a means of indicating the condition of the block. (F.T.M.)

BLOCKING CONDENSER. This is a condenser used at various points in an electrical circuit where it is desirable to pass a.c. and block d.c. It is commonly used

in vacuum-tube circuits to prevent the a-c load from affecting the d-c plate voltage. (L.R.Q.)

BLOCKING LAYER. Photovoltaic Effects.

BLOOD. A liquid tissue whose chief function is the ready transportation of materials through the animal body. In some invertebrates, particularly insects, it is called haemolymph.

All bloods consist of two principal parts: the liquid intercellular material called the plasma, and the cells which are suspended in it. The plasma is a complex mixture containing absorbed products of digestion, waste products of the various tissues, special secretions, enzymes, and antibodies, and gases: **oxygen, carbon dioxide,** and **nitrogen.** The composition of plasma is roughly as follows: water, 90%, proteins, 9%, salts, 0.9%, sugar, urea, uric acid, creatin, etc., traces. All bloods contain white cells or leucocytes and the blood of vertebrates also contains red cells whose function is the transportation of oxygen. (See Plate facing p. 180.)

The transportation of dissolved materials by blood depends upon selective **osmotic** interchange with the tissues with which it comes into contact. The transportation of oxygen is, in some animals, of the same nature but in others, complex proteins containing copper or iron enter into combination with the gas. Haemocyanin (see **Protein**) containing copper and **hemoglobin** (see **Protein**) containing iron, are the two most common compounds known to act in this way. The former is found in some **arthropods** and **mollusks** and the latter in some **nemertine** and **annelid** worms, a few arthropods, the phoronids, and the **vertebrates.** In the vertebrates oxygen is contained in the red cells.

More is known of human blood than of that of any other species because of its importance in medicine. The average amount of blood in the human body is about 1/20 of the body weight or about 4–7 quarts. Arterial blood is bright red due to its relatively high oxygen content. Venous blood is darker in color due to depletion of its oxygen by the tissues. Blood is salty in taste, slightly heavier than water, has a peculiar odor and its normal temperature is about 100° F. In addition to extensive knowledge of the chemistry of the plasma, the normal characteristics of the cell content have been determined and the significance of deviations from the normal has become an important factor in clinical diagnosis. The human red cells or erythrocytes are biconcave disks averaging .0075 mm. in diameter. The enucleate condition is characteristic of mammals but in other vertebrates the nucleus is present. The red cells are filled with hemoglobin, which has the power of combining with oxygen easily and giving up the oxygen readily when the body cells require it. The color of the blood depends on its content of oxygen—the higher the oxygen content, the brighter the color. The principal function of red corpuscles is the transportation of oxygen to the cells and tissues. This function depends upon their hemoglobin content and their total number.

The number of red cells varies. In health the average is 4,500,000–5,000,000 per cu. mm. The hemoglobin content normally varies between 75–100%, or 12–15 grams. Any percentage lower than 75 with a total count of less than 4 million cells is classed as **anemia.**

The red blood cells are manufactured by the marrow cells of the long bones of the body. The average life of red cells is estimated from 50–70 days. They are destroyed, when useless, by the **liver, spleen** and **lymph** nodes.

The white cells are of three types: the lymphocytic, monocytic, and myeloid series. 1. Lymphocytes are 7–18 μ in diameter. Their nuclei are round to oval, deeply staining, and the cytoplasm is clear, with few or no granules. 2. Monocytes are 12–20 μ in diameter and have indented, kidney-shaped nuclei. Their cytoplasm contains abundant fine reddish-blue granules. 3. The myeloid series comprise the granulocytes, which are classified as neutrophils, eosinophils, and basophils, according to whether their granules stain pink, red, or deep blue, respectively, with Wright's stain. All the granulocytes are approximately the same size, varying between 10 and 15 μ in diameter. Their nuclei are lobulated and, for this reason, they are called polymorphonuclear leucocytes.

The total number of circulating white blood cells in a normal adult is between 5000 and 10,000 per cu. mm. Of these 55–65% are polymorphonuclear neutrophils, 1–3% eosinophils, and 0–0 75% basophils; 25–33% are lymphocytes, and 3–7% monocytes. In addition to these cells, there are two other cellular elements, the macrophages—clasmatocytes or histiocytes—and the platelets. The macrophages are derived largely from the monocytic series of leucocytes; they are 15–80 μ in diameter. The blood platelets or thrombocytes are minute (2–4 μ) particles thought to arise from the giant megakaryocytes of the bone marrow. Their function is concerned with the initiation of blood clotting, by their liberation of thromboplastin.

The functions of the leucocytes are multiple, and some of them are as yet little understood. The cells are motile and one of their most important activities is **phagocytosis,** by means of which bacteria and cellular debris are destroyed. The neutrophils engulf bacteria and small particles of material, while monocytes and macrophages phagocytize larger particulate matter, **protozoa,** and red cells. **Enzymes** of various types are produced by the leucocytes, and these are probably responsible for the digestion of engulfed particles. Eosinophils are thought to play some role in **detoxification,** the disintegration and removal of protein. Their number is increased in allergic diseases and with infestations with the intestinal parasites. Nothing is known of the function of basophils. The function of the lymphocytes is obscure also, but they seem to be involved in some way in healing processes and in the body's reaction to foreign protein.

The total number of leucocytes and the ratio between neutrophils and lymphocytes deviates from the normal in the presence of certain diseases, particularly infections. With infections of bacterial rather than virus etiology, a marked increase in the total count (**leucocytosis**) and a high percentage of granulocytes occurs Occasionally, in response to an overwhelming infection, or as a toxic reaction to a drug, the opposite occurs: the total count falls below 5000 per cu. mm. (**leucopenia**) and the percentage of granulocytes drops. This is an unfavorable prognostic sign. **Leukemia** is a fatal disease associated with enormous increases in the white cells of myeloid, lymphocytic, or monocytic series.

Diseases of the blood are numerous. In addition to the leukemias, the most important ones are the various anemias, polycythemia, hemophilia, hemorrhagic purpura, and agranulocytosis. These are discussed under their respective headings. (A.W.L., R.S.M., D.M.H.)

BLOOD GROUPS OR TYPES. There are four recognized groupings of human blood. The blood grouping of a person is hereditary and follows the principles of the Mendelian Law (see **Heredity**); it remains unchanged through life. The presence of blood groups in the human race is due to congenital antigenic differences in the red blood cells of individuals.

Landsteiner, in 1901, first accurately described three of the blood groups. In 1902, the fourth group was added by two of his pupils. Jansky in 1907, in further work, called the groups by numbers, thus, group I, II, III, and IV. In 1910, Moss classified the groups IV, II, III, and I so that Jansky I became Moss IV and Jansky IV became Moss I. This caused considerable confusion and led to the adoption of an international grouping arrangement naming the groups according to

the antigen contained in the cells. Thus the groups are called Group A, B, and AB, and O, depending on whether antigens A, or B, or both are present in the red cells.

Group O is called the universal donor group, because the red cells contain no antigenic factor. However, a group O donor is never used in transfusing patients of other groups unless as an emergency procedure, when there is no time to obtain a donor of the same group.

Blood grouping is vital in the transfusion of blood. Not only must a donor of the same group be used, but his blood must be compatible or must cross-match with the patient's blood.

Lately, grouping has been used legally in establishing paternity. In certain cases it can be proved that the suspected individual could not have been the father. It never can prove that the individual is the father.

In 1940 a new **antigen** was found in human blood, the Rh factor. This factor is present in the red cells of 85% of the population, absent in 15%, and individuals are classified accordingly as Rh positive, or Rh negative.

Although **antibodies** to the Rh factor do not occur spontaneously in the **serum** of Rh-negative individuals, the Rh type is of importance in such people because by repeated **transfusions** with Rh-positive blood, such antibodies may be built up, and a fatal transfusion reaction will result if Rh-positive blood is then given. Rh-negative patients, therefore, should be transfused with Rh-negative blood only. This is of particular importance in obstetrical patients. If an Rh-negative woman is married to an Rh-positive man, 3 out of 4 of their children will be Rh positive. The blood of these children while in utero will stimulate the formation of anti-Rh immune bodies in the mother's blood; if she be given a transfusion with Rh-positive blood, the antibody will react with the Rh antigen, and a fatal transfusion reaction may result.

The Rh-positive fetus of an Rh-negative mother is also in danger: the anti-Rh immune bodies which are built up in the mother's blood diffuse through the **placenta** into the fetal circulation, and an antigen-antibody reaction takes place within the fetus, resulting in the agglutination and destruction of its red cells. Such an infant suffers from erythroblastosis fetalis, a disease whose etiology was unknown until the discovery of the Rh factor. (D.M.H.)

BLOOD PRESSURE. The pressure in the arterial system of the body. (See **Circulatory System.**) This pressure depends upon interrelations between a number of factors, the important ones being (1) the force of contraction of the left **ventricle** of the heart as it pumps forth blood; (2) the volume of blood forced into the **aorta** by the contraction of the left ventricle; (3) the peripheral resistance of the **arteries**, their elasticity and tone; and (4) the viscosity of the blood.

Both systolic and diastolic pressures are measured. The systolic indicates the pressure during **systole**, when the heart is contracting and forcing out blood, while the diastolic indicates the pressure during **diastole**, when the heart muscle is relaxed and its chambers are filling with blood. The normal systolic values are given as 90 to 140 mm. of mercury, and the diastolic 60 to 90 mm. of mercury. These figures vary with age, exercise, degree of obesity, and emotional stress. The normal is thus highly elastic. (D.M.H.)

BLOOD WEAVER-FINCH. Aves, Passeriformes. A group of **weaver-birds** of Arabia and Africa. Named from the prevalence of scarlet in their plumage. (A.W.L.)

BLOOD WORM. 1. **Annelida.** Certain marine worms whose bright red blood gives color to the entire body. 2. Insecta, **Diptera.** The aquatic larvae of certain **midges** which have hemoglobin dissolved in the plasma of the **blood** and so are red in color. (A.W.L.)

BLOODSTONE or **HELIOTROPE.** A massive variety of **quartz** of greenish color with small spots of red **jasper** somewhat resembling blood drops. It is used as a semi-precious stone. When placed in water in full sunlight bloodstone will frequently give a general reddish reflection, hence the term heliotrope, derived from the Greek words meaning sun and to turn. (E.S.C.S.)

BLOWERS. Compressors for compressing air or gas to pressures as high as 35 lbs. per sq. in. gauge are known as blowers. The principal types are the *reciprocating* (blowing tub), *centrifugal,* and *positive displacement rotary* (as exemplified by the Roots blower). A familiar example of the centrifugal blower is the airplane engine supercharger. This has a high-speed, radial-bladed impeller enclosed in a casing so that air, drawn from the atmosphere, may be caught by the impeller and compressed through a range of 20 to 30″ of mercury. The principle of pressure increase is the same as that explained for **air compressors,** *centrifugal.* Centrifugal blowers propelled by steam or gas turbines are called "turbo-blowers."

A Roots-type blower has two irregular, lobe-shaped impellers rotating (in synchronism) within a circular casing. Rotation of the impellers traps air between them and the casing, following this by an expulsion through the discharge port. Clearances between impellers and casing are small, but positive. (F.T.M.)

BLOW-FLY. Insecta, Diptera. **Flies** which deposit their eggs on meat. The name is applied to an entire

EXPLANATION OF PLATE A.

Fig. 1. The cells of normal blood reproduced from actual cells. Wright's stain ×1000 (1 mm. = 1 μ)

1, Red corpuscles and blood platelets. 2, Two lymphocytes. 3, Lymphocyte with azurophilic granules. This cell lay in a thin portion of a film and was exceptionally large. 4, Three endothelial leucocytes, one with fine cytoplasmic granules The granules are rarely so distinct as here shown. 5, Polymorphonuclear neutrophils. 6, Eosinophils, one ruptured. The cells selected for drawing contained fewer granules than are usual. 7, Basophils.

Fig. 2. Leucocytes found in the blood in disease. All reproduced from actual cells stained with Wright's stain, excepting No. 15, which is copied from Pappenheim ×1000 (1 mm. = 1 μ).

8, Two myeloblasts, showing nucleoli. 9, Two promyelocytes. Note the blue edge of one 10, Two mature neutrophilic myelocytes. 11, Eosinophilic myelocyte 12, Basophilic myelocyte. Some of the granules have dissolved, leaving vacuoles and staining the cytoplasm. 13, Two lymphoblasts, one with lobulated nucleus (Rieder cell). 14, Turck's irritation leucocyte with vacuoles 15, Plasma cell. 16, Degenerated nuclei, one a so-called "basket-cell." 17, Neutrophilic leucocyte with vacuoles (toxic change).

DESCRIPTION OF PLATE B.

Abnormal red-corpuscles. All drawn from actual specimens and all stained with Wright's stain except where noted. ×1000 (1 mm. = 1 μ)

Fig. 1. Variations in size, shape, and hemoglobin content; from cases of pernicious anemia and chlorosis.

Fig. 2. Polychromatophilia and basophilic granular degeneration; from cases of lead-poisoning and pernicious anemia.

Fig. 3. Normoblasts, reticulated red cells, and one microblast. The top row represents stages in the development of the normoblast. The two reticulated red cells are stained with brilliant cresyl blue.

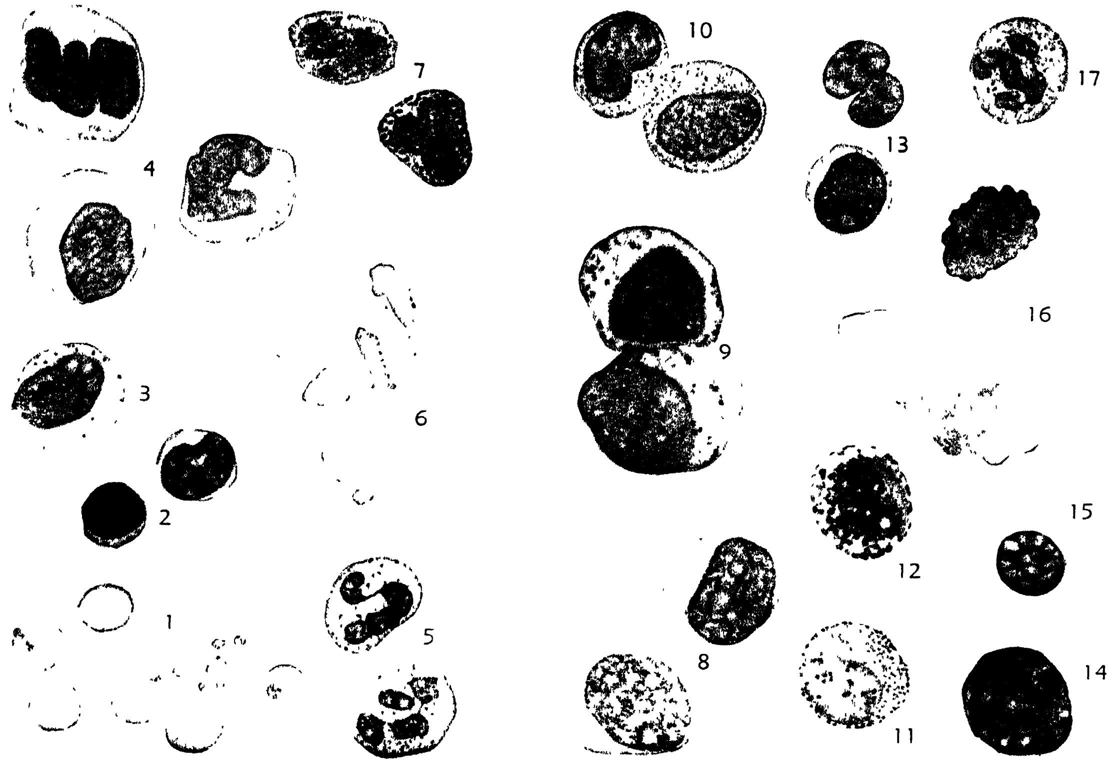
Fig. 4. Megaloblasts from cases of pernicious anemia. Two show polychromatophilia and fairly typical nuclei, two have condensed nuclei, and one of these has basophilic cytoplasmic granules.

Fig. 5. Nuclear particles or "Howell-Jolly bodies" One cell also shows basophilic granular degeneration.

Fig. 6. Mitotic figures, two from myelogenous leukemia, one with polychromatophilic cytoplasm, from von Jaksch's anemia. The last was stained with Leishman's stain.

Fig. 7. Cabot's ring bodies, from a case of von Jaksch's anemia. Two cells also contain nuclear particles and one shows basophilic granular degeneration. Leishman's stain.

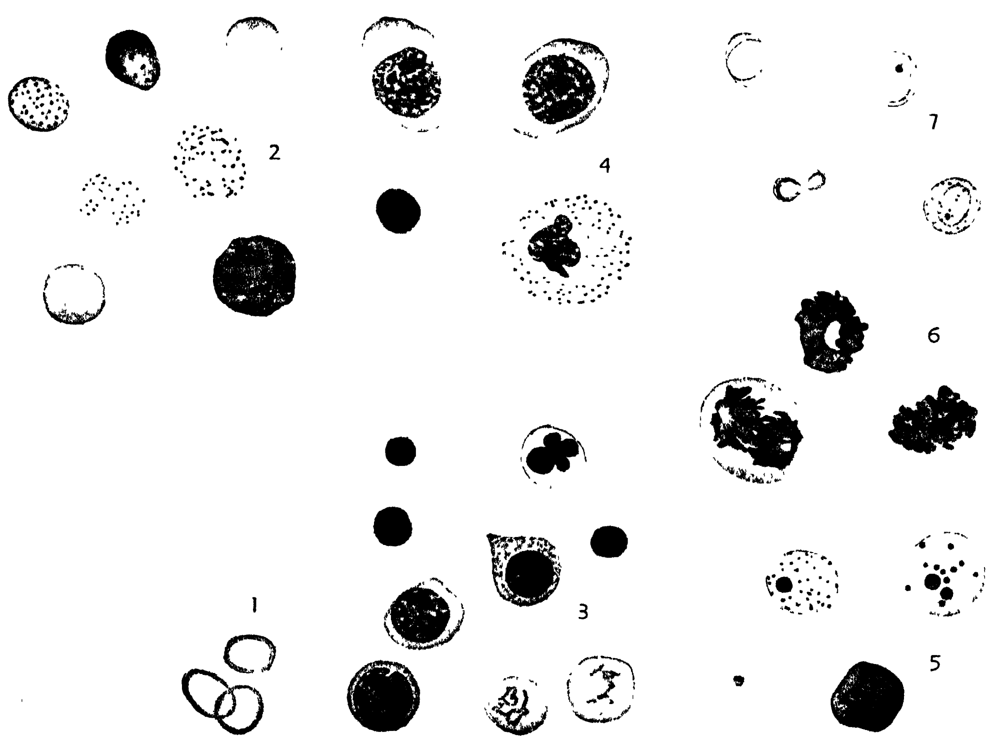
PLATE A



The cells of normal blood (scale 1 mm = 1 μ).

Leucocytes which appear in the blood in disease (scale 1 mm = 1 μ) (J W Rennel, pinx)

PLATE B



See page 180 for detailed discussion of these Plates Reproduced from Todd and Sanford, *Clinical Diagnosis by Laboratory Methods*, courtesy of W. B. Saunders Co.

PLATE C

Malarial Parasites

Wright's stain. × 1000 (1 mm = 1μ).

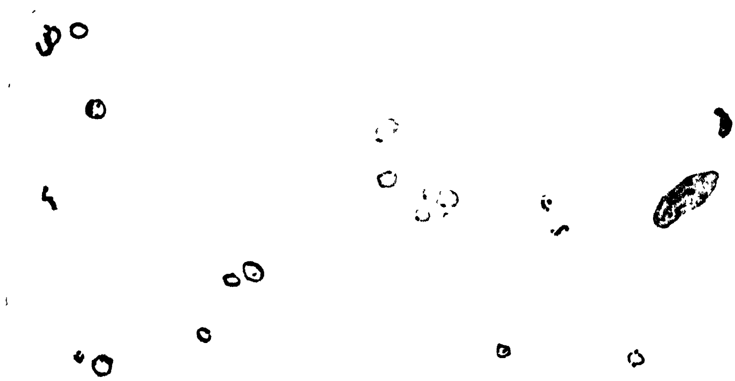


Fig. 1.—Estivo-autumnal malaria, exact reproduction of a portion of a field showing an exceptionally large number of parasites.

Fig. 2.—Estivo-autumnal gametocytes.

Fig. 3.—Leucocytes with engulfed pigment.

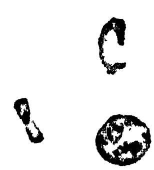

Fig. 4.—Quartan parasites.

Fig. 5.—Tertian parasites. A, Eight hours after chill, showing malarial stippling, five young parasites, and one gametocyte, from two slides. B, twenty-four hours after chill: five half-grown parasites, one gametocyte. C, during chill, one presegmenter, two segmenters, a cluster of freshly liberated merozoites, and two very young parasites, from one slide. (J. W. Rennel, pinx.)

Reproduced from Todd and Sanford, *Clinical Diagnosis by Laboratory Methods*, courtesy of W. B. Saunders Co.

family, however, containing other species which breed in dung, in wounds on living animals, and as blood-sucking parasites of nestling birds. The commoner species are also known as **bluebottle** flies. Family Calliphoridae. (A.W.L.)

BLOW-HOLE. A blow-hole is a defect in a **casting** caused by passage of gases through the metal of the casting during the process of solidification. Large numbers of blow-holes will materially weaken a casting. Even a single blow-hole may be sufficient cause for rejection of castings which are used to contain liquids or gases. The majority of blow-holes are due to the condition of the mold. The use of molding sand which does not vent the gases freely, improper ramming of the sand, or errors in making or placing the cores, are prolific sources of blow-holes.

Blow-holes in steel ***ingots*** are welded during rolling or forging unless oxidation of the internal surfaces occurs, as by exposure of subsurface blow-holes to the air. (F.T.M., R.H.H.)

BLUE. Insecta, Lepidoptera. **Butterflies** whose prevailing color is bright blue. The females are usually less blue than the males and some few species are not blue. With the coppers and hair-streaks they constitute the family Lycaenidae. (A.W.L.)

BLUE BRITTLENESS. Steels mechanically worked in the temperature range of 300–700° F. are less plastic than at lower or higher temperatures. Because a blue oxide surface film forms upon heating to about 550° F. the phenomenon has become known as blue brittleness. (R.H.H.)

BLUE EARTH. Kimberlite.

BLUE GROUND. Kimberlite.

BLUE MUD. A typical deep sea, fine-grained sediment containing an appreciable amount of **calcium** carbonate. The bluish-gray color is caused by organic matter and finely divided **iron** sulfide. (R.M.F.)

BLUE PRINT. Paper coated with ammonium **ferric citrate** or **oxalate** and **potassium** ferricyanide. On exposure to light the ferric ion is reduced to ferrous, and on subsequent treatment with water the ferrous ion forms ferrous ferricyanide which is blue while the ferric ion forms the brown ferric ferricyanide which is washed off the paper. (See **Drawing Reproduction.**) (R.K.S.)

BLUE RACER. Reptilia, Sauria. A variety of the **blacksnake** found in the prairie and plains states. Like many snakes, it has a bad reputation but is quite harmless. *Zamenis constrictor.* (A.W.L.)

BLUEBACK. Pisces, Teleostei. A commercially important **salmon,** said to be second only to the king salmon in this respect. It ranges from California to Alaska. Also called the redfish. Also a species of **trout** found in Maine and northward. (A.W.L.)

BLUEBERRY. Heath Family.

BLUEBIRD. Aves, Passeriformes. 1. Several species of North American **thrushes** whose prevailing color is blue. Of these the male mountain bluebird, *Sialia currucoides,* of the West is entirely blue while other species are marked with shades of reddish brown. 2. One of the **babblers** of the Oriental region. 3. Said to be applied to a South African **albatross** (Order Procellariiformes). (A.W.L.)

BLUEBOTTLE. Insecta, Diptera. Large **flies** of shining blue, green or purple color. They lay their eggs on meat and other foods and so are often seen in dwellings. (A.W.L.)

BLUEFIN. Pisces, Teleostei. A fish (**Pisces**) found in the Great Lakes and smaller lakes of the same region; one of the lake herrings, also called the blackfin. *Leucichthys nigripinnis.*. (A.W.L.)

BLUEGILL. Pisces, Teleostei. A fish (**Pisces**), *Helioperca incisor,* related to the sunfishes and bass. Widely distributed east of the Rockies in lakes and the quieter parts of streams and esteemed as a pan fish. It attains a length of 10″ or more but in well-fished waters rarely attains this size. Although small, it rises readily to a fly and so ranks among desirable game fishes. (A.W.L.)

BLUETHROAT. Aves, Passeriformes. A European bird (**Aves**) related to the warblers. *Luscinia suecica.* (A.W.L.)

BLUFF BODY. An object immersed in fluid stream flow is said to be bluff (or blunt) if its shape promotes a rapidly increasing downstream pressure gradient in the streamline flow around it. A high adverse gradient assists the creation of a **stagnation point.** The streamline flow breaks loose from the surface of the body on either side, leaving a turbulent low-pressure wake. This wake causes the characteristically high drag of bluff bodies. (See **Aerodynamics.**) (F.T.M.)

BLUNT-NOSE. Pisces, Teleostei. A small fish (**Pisces**), *Hyborhynchus notatus,* found in streams west of the Alleghanies, related to the dace and chub. (A.W.L.)

BOA. Reptilia, Sauria. Any **snake** of the family Boidae. The United States has only two small species of the western states; the bulk of the family is made up of large arboreal snakes such as the **boa-constrictors,** *Boa constrictor,* of South America and the **pythons,** *Python,* of the Old World. One of these species, the **anaconda,** *Eunectes murinus,* attains a length of over 30′ and is the largest snake known. Boas are not poisonous. (A.W.L.)

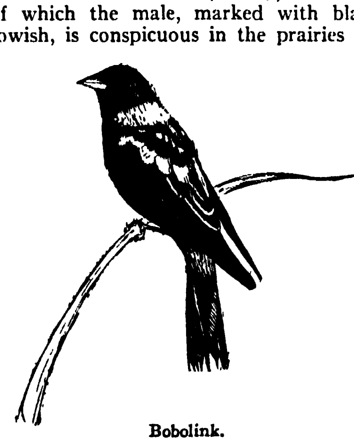
BOAR. The male of any species of swine. (See **Pig.**) The term wild boar is also applied generally to two species found respectively in India, *Sus cristatus,* and in Europe and the adjoining areas of Asia and Africa, *S. scrofa.* (A.W.L.)

BOARD DROP. Forging.

BOBAC. Marmot.

BOBCAT. Wildcat.

BOBOLINK. Aves, Passeriformes. A widely distributed North American bird (**Aves**), *Dolichonyx oryzivorus,* of which the male, marked with black, white, and yellowish, is conspicuous in the prairies and mead-



Bobolink.

ows where the species breeds. The female is duller and plainer. The bobolink is noted for its cheerful song. (A.W.L.)

BOB-WHITE. Quail.

BODE'S LAW. In the latter part of the 18th century an empirical relationship was noticed between the mean distances of the various **planets** from the sun. This relationship was first published by Bode in 1772 and has since become known as Bode's Law, in spite of the fact that there is certain evidence that it was known and used by Titus a number of years previous to the time of its announcement.

Bode's Law may be stated as follows: write down a series of 4's; to the first one add 0, to the second one add 3, to the third one add $6 = 3 \times 2$, to the fourth one $12 = 6 \times 2$, to the fifth $24 = 12 \times 2$, etc.; the resulting numbers divided by 10 will give the approximate mean distances of the planets from the sun in **astronomical units.** The sequence is as follows:

Planet	Bode Distance	Mean Distance
Mercury	4 + 0 = 4	0 39
Venus	4 + 3 = 7	0 72
Earth	4 + 6 = 10	1.00
Mars	4 + 12 = 16	1 52
	4 + 24 = 28	
Jupiter	4 + 48 = 52	5 20
Saturn	4 + 96 = 100	9 53
Uranus	4 + 192 = 196	19 19
Neptune	4 + 384 = 388	30 07
Pluto	4 + 768 = 772	39 5

The value in the last column is the actual mean distance of the planet from the sun in astronomical units.

At the time that the law was first proposed the gap between Mars and Jupiter was not filled and no planets were known outside of Saturn. The law predicted distances and when Uranus was discovered with mean distance so close to the predicted value, Bode's Law was believed to be established. The discovery of the **asteroid** Ceres with a mean distance of 2.77 gave further support to the validity of the law. It is interesting to note that, in making the computations which led to the discovery of **Neptune,** Adams used the predicted Bode distance for the then unknown object.

During the 19th century many unsuccessful attempts were made to place Bode's Law upon a theoretical foundation. The failure of the law in the cases of Neptune and Pluto has convinced most astronomers that the law is a purely empirical relationship, more in the realm of coincidence than an actual physical law. (W.K.G.)

BODY CAPACITANCE. This refers to the capacitance effect produced when the operator's hand is brought near a vacuum-tube circuit. Since many of these circuits, especially those employing tuned circuits, are very sensitive to small changes in the capacitance coupling to surrounding objects, the bringing of the hand near any of the circuit conductors will materially alter the response of the circuit. Such effects can be minimized by shielding the circuit and by appropriate grounding. (L.R.Q.)

BOEHMERIA NIVEA. Urticaceae. A perennial Asiatic plant growing up to 7′ in height and producing several crops of canes annually. Cultivation of the plant occurs principally in China, although smaller quantities are grown in other Oriental countries. The plant is grown for its pericyclic fibers, which are both long (up to 200 mm.) and of unusual strength, though they do not stand twisting very well. In the Orient these fibers are removed from the plant entirely by manual labor, the cortex is scraped off by drawing the stems over a coarse knife against which they are pressed. The fibers obtained by this process are dried, and in this condition are known as "China Grass." Repeated washing and drying is next used to remove the gummy substance which surrounds the fibers and to separate them, a slow tiresome process. Ramie fibers are considerably coarser than those of flax, and have great tensile strength, but are little used because of their lack of resistance to twisting. Cultivation has been attempted in the United States, but without much success, because of the difficulty of preparing the fibers for manufacturing processes. (R.M.W.)

BOEHMITE. Lepidocrocite.

BOG IRON. Limonite.

BOG MANGANESE. Wad.

BOIL. Furuncle. A localized purulent infection of the skin and underlying tissues, usually caused by the **Stapylococcus** group of micro-organisms. It is characterized by destruction of tissue in its center (core), with softening and discharge of pus. Treatment is surgical incision and drainage. (R.S.M., D.M.H.)

BOILER EFFICIENCY. By boiler efficiency is meant the measure of ability of a boiler to transfer the heat given it by the **furnace** to the water and steam. This will sometimes include **superheater** performance. Boiler and furnace are so much a unit nowadays that "boiler and furnace" efficiency is more important than boiler efficiency. In fact, boiler efficiency is often taken with the meaning of boiler and furnace efficiency; that is, the percentage of the higher heating value of the fuel which will be in the steam. Efficiency is also designated by "evaporation," which is simply the pounds of steam produced per pound of fuel fired. This evaporation may be either the actual evaporation or the equivalent evaporation that would be obtained with the same heat producing steam at 212° F. from feedwater at 212° F.

In the light of the second law of **thermodynamics,** it would hardly seem right to charge the boiler with being unable to absorb any of the heat that was at a lower thermal level than the boiler itself. The "true boiler efficiency" is an expression used to denote that portion of the heat above the saturation temperature which is absorbed by the boiler. It is obtained by dividing the heat absorbed by the boiler by the heat liberated in combustion, less the heat regained if the products of combustion were cooled from the boiler saturation temperature to atmospheric temperature. (F.T.M.)

BOILER HORSEPOWER. The term boiler horsepower was defined in 1876. At that time the average engine would operate on 30 lbs. of steam per horsepower per hour, and a boiler horsepower was defined as the capacity to generate steam at that rate. The average rate of evaporation, then, was 3 lbs. of steam per sq. ft. of heating surface per hour in a water tube boiler, so 10 sq. ft. of heating surface was accepted as manufacturer's rating for a boiler horsepower. The 10:30 ratio of heating surface to steam rate became obsolete when steam rates were reduced to less than 10 lbs. per horsepower hour through improvements in steam turbines and engines, and evaporative rates were increased from 10 to 15 lbs. per sq. ft. per hour by improvements in boiler design and manufacture. Yet the 10 sq. ft. per boiler horsepower persisted, so that now capacity can be expressed in terms of the manufacturer's horsepower rating only by misuse of the term "per cent rating." For instance, an 8000 sq. ft. boiler when producing 72,000 lbs. of steam per hour would be said to be operating on 300% rating. This might be construed to mean an overload of 200% on some equipment, but it would be the normal load for the boiler. When the significance of the term "per cent rating" is understood, there is no

disadvantage to the use of boiler horsepower actually developed, as 1 boiler horsepower = 33,500 B.T.U. per hour transferred to the water. (F.T.M.)

BOILER TEST. The performance of a steam generating unit cannot be gauged by visual inspection of the equipment in operation. Yet an understanding of where the heat units are going, what portion of them are usefully retained and what portion lost, and of those lost, how they are lost, and whether the losses are tending to increase, or whether they may be reduced, is highly desirable whenever there is an attempt to operate a boiler plant with the highest standards of technique and economy. Furthermore, a breakdown of costs often requires definite numerical data as to the performance of the steam generating unit. Then, too, there is always the natural curiosity of boiler operators as to the results they are getting from their equipment, and whether these results are the best that can possibly be obtained. This information can be secured by a test upon a **boiler**, although a complete test is a job of no little magnitude.

Most boiler tests are planned to obtain sufficient data to set forth the results in the form of the balance called for in the **boiler test code.** The test information that must be obtained is as follows: First, there is an analysis to determine the percentage of constituent gases present in the products of combustion. These gases are some or all of the following: **nitrogen, carbon dioxide, carbon monoxide,** and **oxygen.** Their relative proportions are obtained by a gas analyzer known as the Orsat apparatus. The temperature of the products of combustion (called flue gas) at the exit from the **boiler** must also be taken. The ultimate chemical analysis of the **fuel** in the state as fired is determined for a representative sample of the fuel used during the test. Then if there is refuse, such as the ash of a coal-fired furnace, that refuse must be analyzed for the presence of unburned combustible. The atmospheric conditions of temperature and humidity are also needed, although frequently the effect of moisture in the air is neglected, and humidity readings are omitted. The boiler test is made over an extended period of time to eliminate the effect of small irregularities of load, and no test of less than one hour's duration should be considered worth while. Tests are more frequently run for a period of three to twelve hours. The amount of steam produced during this period, as well as the weight of fuel fired, temperature of the feedwater, steam pressure and temperature, complete the information required to determine the distribution of the total heat available in the fuel, between useful heat and the various losses. The computations involved are quite beyond the scope of this article, but will be found adequately explained in any good book on heat engineering. (F.T.M.)

BOILER TEST CODE. Many years ago the need for a set of rules and regulations standardizing the method of reporting the results of a steam boiler test was felt to be necessary for true comparison and evaluation of performance. The accepted code is a project of the American Society of Mechanical Engineers. The test code is, in reality, an arithmetical balance of the heat entering a steam generating unit against the heat leaving. The heat in the coal or other fuel fired into the furnace must be accounted for either as useful heat or as one or the other of several different losses. A **boiler test** is performed to obtain the information necessary to account for the heat produced by combustion of the fuel.

The boiler test code for stationary steam generating units has the following items:

1. Heat absorbed by the boiler.
2. Loss due to moisture in coal.
3. Loss due to water formed by burning of hydrogen.
4. Loss due to hygroscopic moisture in air.
5. Loss due to heat carried away in dry chimney gas.
6. Loss due to incomplete combustion of carbon.
7. Loss due to unconsumed combustible in refuse.
8. Loss due to unconsumed hydrogen and hydrocarbons, radiation, and other losses.

The sum of these eight items should be equal to the higher heat value of the fuel. (F.T.M.)

BOILERS. A boiler is a pressure vessel designed to transmit heat developed by combustion of a fuel to water and steam contained in the boiler. In some instances the liquid in a boiler has been something other than water, but the purpose of this article is to discuss the **steam** boiler. The boiler should hold its contents safely and deliver the steam in the desired condition. It is desirable, also, from the standpoint of economy that the heat be transmitted with minimum loss to the atmosphere.

The steam boiler is an external combustion device, that is, the combustion takes place externally from the region of boiling water. This fact, then, implies the existence of a surface separating the interior of the boiler from the combustion zone. All of the heat which reaches the water must be transferred through this surface. It is called the **heating surface.** All but a very small portion of the surface encircling the water and steam region of a boiler is heating surface. Some boilers are built so that the heating surface encloses the furnace, while others have furnaces built as an auxiliary to the boiler. In the latter the boiler and furnace are enclosed in a refractory, heat-insulating casing called the setting.

Heat generated by **combustion** is transferred to the heating surfaces in two ways. The surfaces which might be said to "see" the incandescent region of combustion receive heat at a rapid rate by **radiation.** Other portions may receive heat by **convection** from the products of combustion which have been heated in the furnace and act as vehicles for transportation of heat to the boiler surface. The heat is transferred by **conduction** from the gas side of the heating surface through the metal to the water.

Beginning with the simple cylindrical shell type boiler, heated with flames applied to the outer surface, many and varied types of boilers have been evolved. Some have characteristics which fit them for marine service, others for land service, others for heating, etc. For a comprehensive picture of the whole field, it is well to classify the group in logical order. The following table illustrates various classifications.

Classification of Boilers

1. On the basis of the contents of the tubular heating surfaces.
   a. Fire tube, having flame and products of combustion in the tubes.
   b. Water tube, having the water and steam in the tubes, and the products of combustion outside.
2. On the basis of position of the furnace.
   a. Internally fired.
   The internally fired boiler has the furnace region completely surrounded by heating surface, as in the small portable vertical boilers, the Scotch boiler, or the locomotive boiler.
   b. Externally fired.
   All water tube boilers are externally fired, and one of the fire tube class, the horizontal return tubular, is externally fired.
3. On the basis of the shape and position of the tubular heating surface.
   a. The inclination of the tubes, as horizontal, inclined, or vertical.
   b. The form of the tubes—straight or bent.
4. On the basis of the drums.
   a. The number of drums, as single drum, two drum, or multiple drum.
   b. The position of the drum with respect to the tubes, that is to say, across the tubes or

parallel to the tubes, giving rise to the names cross-drum and long-drum.

5. On the basis of the type of headers employed to connect the tubes to the drums.
   a. Sinuous, forged steel headers having a number of individual sections. Each section serves the tubes in a single vertical row, and there are as many sections side by side as the tube bank is wide.
   b. The box type riveted header, made of plate steel, and having sufficient area for the accommodation of all tube connections.

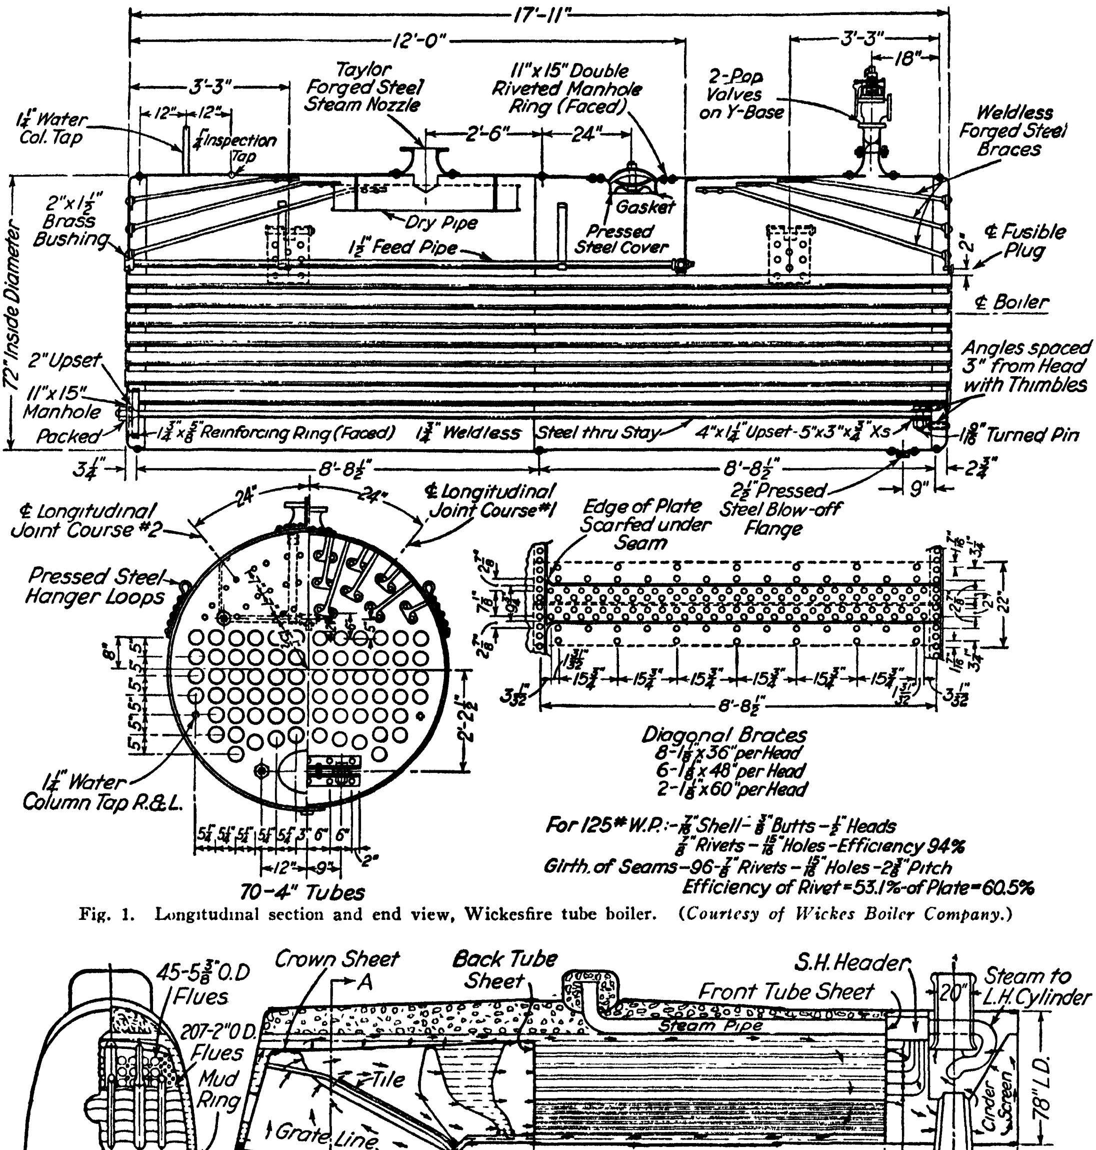


Fig. 1. Longitudinal section and end view, Wickesfire tube boiler. (*Courtesy of Wickes Boiler Company.*)

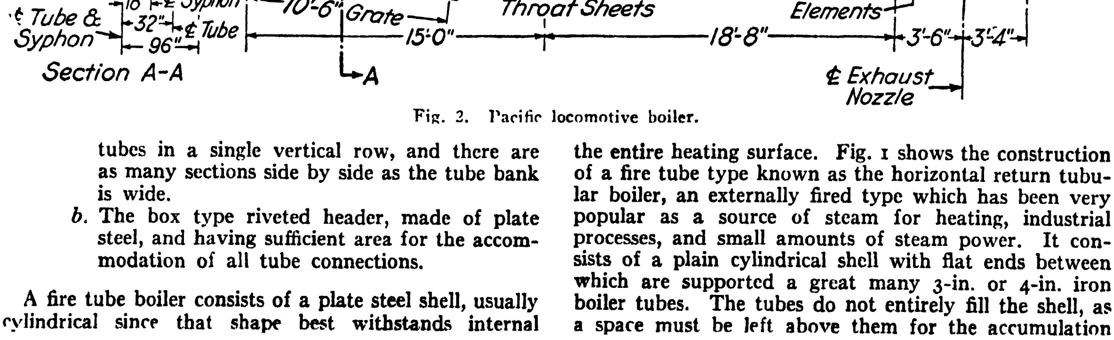

Fig. 2. Pacific locomotive boiler.

A fire tube boiler consists of a plate steel shell, usually cylindrical since that shape best withstands internal bursting pressure. Holes are bored in the tube sheets, which are the ends of the cylinder, in such a manner that tubes may be passed through the shell and fastened tightly in the holes. These tubes are submerged in the water within the boiler, and hot gas passes through them. In some boilers the surface of the tubes comprises the entire heating surface. Fig. 1 shows the construction of a fire tube type known as the horizontal return tubular boiler, an externally fired type which has been very popular as a source of steam for heating, industrial processes, and small amounts of steam power. It consists of a plain cylindrical shell with flat ends between which are supported a great many 3-in. or 4-in. iron boiler tubes. The tubes do not entirely fill the shell, as a space must be left above them for the accumulation

and storage of steam. The tube sheets above the tubes are braced against bulging by steel stay braces. The boiler is completed by the addition of proper taps for instruments, steam leads, feed water pipe, and safety devices, and with the provision for some means of supporting it, such as brackets or loops. The furnace is built below and external to the boiler shell, and both furnace and boiler are enclosed in a brick setting. The flames and hot gases play against the bottom of the shell, pass from the front to the back, and return to the front of the boiler through the tubes. The lower portion of the shell and the tubes form the heating surface.

Slightly different is the arrangement of the locomotive fire tube boiler, shown in Fig. 2, where the boiler is internally fired, and the flame and hot gases leaving the furnace region pass forward through the tubes. They emerge from the tubes into the smoke box, from whence they are blown to the atmosphere through a short stack, under the influence of a steam jet which receives steam from the exhaust of the locomotive cylinders. The heating surface consists of the tubes and the shell surrounding the furnace.

A water tube boiler is composed of drums and tubes, the tubes always being external to the drums, and a means of joining the tubes to the drums. The drums are used for storage of water and steam, and for connections of steam and water pipes. As they are not required to contain any tubular heating surface, they are much smaller in diameter than the shells of fire tube boilers, and can be built for higher boiler pressures than are possible in fire tube design. The heating surface is entirely in the tubes, the function of which is therefore simply to absorb the heat and generate the steam. The method of joining a tube to a boiler or header is to insert that tube into a hole having the same diameter as the outside of the tube (tubes are sized on their external diameter, whereas pipes are sized by the nominal internal diameter). The tube wall is forcibly expanded or rolled against the metal surrounding the hole, so as to make a tight joint. This process requires that the axis of the tube be perpendicular to the plane of the hole, or if the hole is bored in a curved surface, the axis of the tube must be radial to the curvature of the surface. If tubes are expanded directly into the drums, dispensing with an intervening header, the only row of tubes that may be absolutely straight is that row that lies in the surface which joins the center lines of two parallel drums. All other rows of tubes must be bent at their ends so as to enter the drum surface radially. Some headerless boilers are built entirely with straight tubes by connecting the tubes to the flat ends of cylindrical drums, but the more common construction is that shown in Fig. 3, where it can be clearly seen that the tubes are bent.

The common construction of a straight tube boiler involves the interposition between the tubes and the drum of a header which will provide a flat surface for the connection of the tubes, and which is connected to the drum by means of circulation tubes or sheet steel saddles. Fig. 4 shows the arrangement of surface in a straight tube box header boiler. As it is necessary to incline the tubes slightly to the horizontal in order to promote water circulation, the box type header must necessarily be inclined somewhat to the vertical, since the surface of the header must be perpendicular to the tubes. Sectional forged steel headers may be exactly vertical, since an inclined surface may be forged at the opening for each tube so that the hole will be perpendicular to the axis of the tube.

The materials from which boilers are constructed are steel and iron. The low-pressure steam boilers so frequently employed in steam heating systems are generally made up of cast iron sections. This material is entirely too weak and heavy for pressure boilers and rolled sheet iron and steel are employed in its place. The tubes are generally seamless iron or steel, and the drums are made of rolled steel sheets which are fabricated by welding or riveting, or both.

In operation, a boiler is supplied with heat from the combustion of a fuel, and with water from a pump

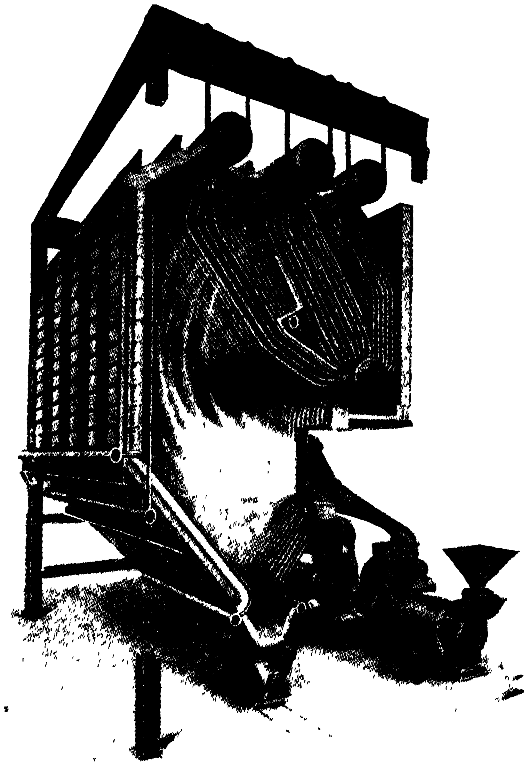

Fig. 3. Boiler equipped with water walls and fired by pulverized coal.

known as the boiler feed pump which is capable of overcoming the pressure existing in the boiler. Upon entrance to the boiler, the water absorbs heat until it reaches its boiling temperature, and is then boiled off to

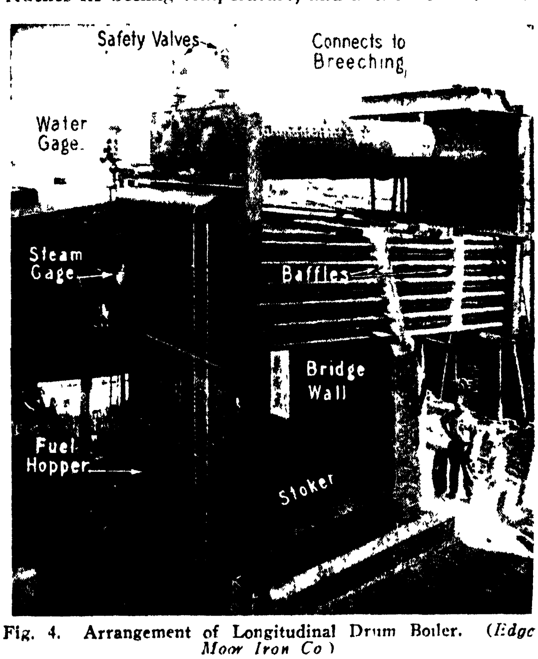

Fig. 4. Arrangement of Longitudinal Drum Boiler. (*Edge Moor Iron Co.*)

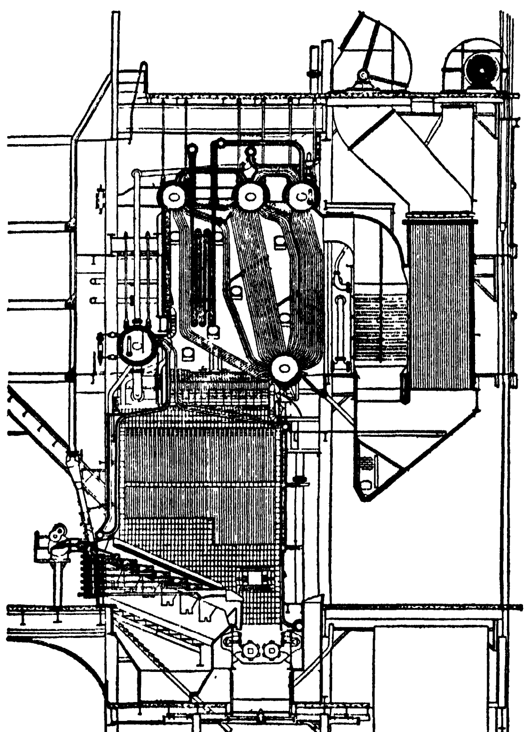
form steam, which collects in the highest part of the boiler drum because of the difference in density of steam and water. Fresh feed water must be introduced to take the place of all steam generated and withdrawn from the boiler, so that the water level will be maintained at the proper position—midway up the drum of a water tube boiler, and above the level of the tubes in a fire tube boiler. Safety devices to protect against low water and high pressure must be provided. In addition to these safety devices, however, boilers are equipped with other auxiliaries, such as dry pipes to filter the entrained droplets of water from the steam and deliver dry steam at the steam nozzle, water level gauge, drain and blow-down connections, **superheaters**, soot blowers, **water walls**, and steam pressure gauges. Operation of the whole steam generating unit may also involve combustion equipment, draft fans, chimney, boiler feed pump, breechings, **economizer**, and **air preheater**. Fig. 5 shows a sectional drawing of a large power boiler in



American Engineering Co.

Fig. 5. Cross-section of steam generating unit, Delray No. 3 Station, Detroit Edison.

which many of these auxiliaries are pictured. An air preheater and economizer, fans, water wall, stoker, and superheater may be noted.

The capacity of a boiler is frequently given in terms of horsepower. A rated **boiler horsepower** is 10 sq. ft. of heating surface for a water tube boiler, and 12 sq. ft. for a fire tube boiler. The rated heat transfer capacity of 10 sq. ft. of heating surface is 33,500 B.T.U. passed to the water in an hour, but since modern boilers can exceed this figure steadily without being overloaded, actual capacity is more than rated capacity, a situation which makes necessary the use of the term "per cent rating."

The selection of a boiler is likely to be greatly influenced by personal prejudice or previous experience of the owner. Given service conditions can usually be met equally well by several boilers of different design. However, in spite of the wide variations in design, there are certain requirements which are fundamental to all water tube boilers. All boilers deserving consideration should meet these requirements, though, of course, not all the favorable points of different designs are covered. But it is nearly certain that if the boiler does not conform to them, operating difficulties will occur early in its life. First, there are the conditions governing the behavior of the water within the boiler. Most important of these is good water circulation. The process of evolution in boiler development has eliminated types with faulty circulation. The disengagement surface where the steam breaks through the surface of the water in the drum should be unrestricted. Priming of the steam with droplets of moisture may result from restricted disengagement surface. In order to control impurities which will be precipitated from the feedwater, it should discharge into the drum at a point where the circulation will deposit the precipitate in a settling chamber called the mud drum. For example, on a boiler in which the mud drum is at the bottom of the rear header, the feedwater should be introduced where the precipitate will be swept out of the drum and into a downcomer leading to the header. Adequate storage space for steam is a requirement indirectly connected with water conditions. The volume of steam storage should conform to the demands of the load served. Insufficient storage space has a bad effect on steadiness of steam pressure under variable load, and has been known to cause pulsations in the boiler and steam piping.

The path of the gases through the boiler should be so baffled and directed over the tubes that they give up heat to the required degree. This required degree is less when auxiliary heat transfer surface in economizer or air preheater are provided than when they are absent Certain features of a boiler may result in undetermined thermal stresses being set up, such as the discharge of cold feedwater against the boiler shell setting up contraction stresses. Joints and seams should be well protected from the flames, and burners should never be set so the flames play directly against tube surfaces. To provide for intelligent and safe operation of the boiler a full complement of leads, gauges, and safety devices should be provided. These would include blow off, steam lead, feedwater lead, water gauge, pressure gauge, safety valve, and fusable plugs. By no means the least important requirement is the necessity of having an accessible boiler. This need is true of all boilers which are expected to be insured, in order that the insuring companies' inspectors may from time to time determine the state of the risk. Acessibility is also needed for maintenance, inspection, and repair by the regular boiler operating personnel. (F.T.M.)

BOILING POINT. The normal boiling point of a **liquid** is the temperature at which its maximum or "saturated" **vapor pressure** is equal to the normal **atmospheric pressure**, 760 mm. of mercury. If the pressure on the liquid varies, the actual boiling point varies in accordance with the relation between the vapor pressure and the temperature for the liquid in question. (See **Vapors.**) Water, for example, with a normal boiling point of 100° C. or 212° F., boils at ordinary room temperature when the pressure is reduced to about 17 mm.; and inhabitants of elevated regions often find difficulty in cooking food by boiling, because of the low boiling point. On the other hand, the boiling water and steam in a "pressure cooker" are so hot that such foods as meat and rice are cooked tender in a very short time. If a solid is dissolved in the liquid, or if another, less volatile liquid is mixed with it, the boiling point is raised to a degree expressed by the boiling point laws of van't Hoff, Raoult, and others. (See **Solutions.**)

A liquid does not necessarily begin boiling when the temperature reaches the boiling point. If kept perfectly

quiet, and especially if covered with a film of oil, water may be raised several degrees above its normal boiling point, before it suddenly boils with explosive violence; it then returns to its true boiling point. (See **Ebullition.**)

Following is a brief table of normal boiling points:

SUBSTANCE	B.P. (°C.)	SUBSTANCE	B.P. (°C.)
Alcohol	78.3	Glycerin	291
Benzene (C_6H_6)	80.0	Helium	−272
Bromine	58.8	Hydrogen	−259
Carbon disulfide	46.3	Mercury	357
Chloroform	61.2	Turpentine	159
Ether	34.6	Water	100

(L.D.W.)

BOLE. A fine-grained, sticky, bright red **laterite**; the decomposition product of **basic igneous** rocks, such as **basalt.** (R.M.F.)

BOLIDE. Bolide is the term applied to **meteors** which are observed to explode in the air and break up into two or more fragments. Such objects are frequently described as having the appearance of an exploding rocket. Not infrequently following the explosion of a bolide a sharp detonation is heard. (W.K.G.)

BOLL WEEVIL. Insecta, Coleoptera. A **snout-beetle** or **weevil,** *Anthonomus grandis,* averaging about ¼″ in length, which damages cotton. The adult punctures the cotton squares to lay its eggs and thus prevents the formation of the boll, and later in the season deposits eggs in the bolls, where its larvae damage the seeds and lint.

The species entered the United States from Mexico in the early nineties and is now an established pest in practically all cotton-growing areas, causing annual loss estimated at $200,000,000. The problem is met by various methods of keeping the insect in check. The destruction of cotton plants after the crop is harvested kills many insects, and dusting the growing plants with **calcium arsenate** has been found effective. The powder is applied by hand dusters in small fields or by larger power dusters where necessary. Airplanes have been used in recent years for dusting on a large scale. (A.W.L.)

BOLLWORM. Insecta, Lepidoptera. The pink cotton bollworm is a small **moth** whose **larva,** the bollworm proper, lives in the flowers of cotton and usually prevents their maturing, and later enters the bolls and damages the seed and lint. The species lives on several other species of plants and is therefore difficult to check, although it is not yet as serious a pest as the boll weevil. The larva of another moth of larger size, more widely known as the corn earworm, also attacks cotton squares and bolls, as well as corn and tobacco, and so is known as the cotton bollworm. It is estimated to cause several millions of dollars damage each year. Fall plowing and disking are practiced to destroy this insect in the pupal stage, which is passed in the ground, and dusting as for the weevil is effective. (A.W.L.)

BOLOMETER. A very sensitive **thermometric** instrument of the metallic **resistance** type, devised by Langley and used for measuring feeble **radiation.** It consists of a slender strip of platinum mounted at the lower end of a long cylindrical tube having circular stops across it at intervals to screen off all radiation except that to be observed. A slight amount of radiant energy falling upon the strip causes a measurable deflection in a sensitive galvanometer in the resistance **bridge** coupled with it. The sensitivity of the instrument is of the same order as that of the **radiomicrometer** of Boys. When a bolometer tube is mounted as the receiving element of a spectroscope, instead of the usual observing telescope or camera, the instrument may be used to detect and measure the lines or bands of **infra-red** spectra. This arrangement is called a spectrobolometer. (L.D.W.)

BOLSON. An undrained basin in an arid region, which generally is partly filled with rock-waste washed by temporary streams from the bordering mountains. (R.M.F.)

BOLT. **Screw Fastening.**

BOLTZMANN CONSTANT. **Ideal Gas Law.**

BOLTZMANN'S PRINCIPLE. A somewhat general law relating to the statistical distribution of large numbers of minute particles subject to thermal agitation and acted upon by a **magnetic,** an **electric,** or a **gravitational field,** or by **inertia.** The number of particles per unit volume in any region of the field, when the system is in statistical **equilibrium,** is given by the equation

$$N = N_0 e^{-\frac{E}{kT}}$$

Here E is the **potential energy** of a particle in the given region, N_0 is the number per unit volume in a region of the field where E is zero, k is Boltzmann's constant (ideal gas constant per molecule), and T is the absolute temperature of the system of particles. Such an equilibrium may exist, for example, in a mass of electrified colloidal particles kept in suspension by their **Brownian movement** while acted upon by an electric field. A well-known special case is Laplace's "law of atmospheres," treated in the **kinetic theory** of gases. (L.D.W.)

BOMB, VOLCANIC. **Lapilli.**

BOMBARDIER BEETLE. Insecta, Coleoptera. A **ground-beetle** which discharges a strong-smelling volatile secretion in small jets when disturbed. Each discharge is accomplished by an audible report and a visible puff of vapor as the secretion evaporates. The numerous species make up the genus *Brachinus.* (A.W.L.)

BOND. Chemical bonds are discussed under **valence.** Electrical bonds are conductors connected between metal shapes, when those shapes do not constitute an effective electrical circuit. Railroad rails, for example, are used for the **block signal** circuit. In order to utilize them for that service, the rails must be electrically continuous. The bonding of a rail consists of attaching a conductor firmly between adjacent rail ends so that a positive path for flow of electric current will replace the haphazard and unreliable circuit that would be comprised by the ordinary rail construction in which rails are connected mechanically by fishplates. The contact resistance at these plates is too great, and so a short bonding connection is used. Bonding may be dispensed with when the rails are welded together. Bonding is also necessary where a radio is installed in a metal framework, some parts of which are bolted together. These joints, where the electrical contact is a surface contact, are frequently by-passed electrically by a bond. Aircraft and automobiles are often bonded this way.

Mechanical bonds play an important part in many structures.

The grip exerted by one material on another when in contact is called bond. The bond resistance is measured in lbs. per sq. in. of contact surface. The theory of reinforced **concrete** design takes into account the bond existing between the concrete and the reinforcing steel. This bond is the result of the molecular attraction called adhesion and the frictional force resulting from the shrinkage of the concrete around the rods. The intensity of the bond depends upon the proportions of the concrete, the age of the mix, the condition of the surface of the rods and the kind of rods used Reinforcing rods which are made with irregular surfaces are

called deformed rods and are able to exert a greater bond resistance than plain rods. (See **Grinding, Silicate Bond, Vitrified Bond.**) (F.T.M.)

BONDERIZING. Parkerizing.

BOND STRESS. Stress.

BONE. A rigid supporting tissue of which the skeleton of **vertebrates** is composed. Its rigidity is due to deposits of inorganic salts, chiefly **calcium phosphate** combined with some calcium carbonate, between the living components of the tissue. **Cells** are scattered throughout this hard matrix and at intervals it is penetrated by blood vessels and nerves which are necessary for the maintenance of its living parts. The matrix is also penetrated by a foundation of organic **fibrils** produced by the cells.

Bone occurs in two forms: compact bone such as the walls of the long bones of the skeleton, and cancellous bone composed of a reticular arrangement of slender parts which results in a spongy appearance. The latter is found in the ends of long bones, among other situations.

Compact bone is made up of thin plates called lamellae arranged in a definite plan. At the surface they follow the periphery of the bone but inside of the compact mass they are arranged concentrically about slender canals which run lengthwise of the bone. These cylindrical components are called Haversian systems; the central Haversian canal contains blood vessels and a small amount of connective tissue, together with the nerve fibers which supply these parts. Nourishment reaches the cells which lie among the surrounding lamellae by way of protoplasmic processes lying in minute canaliculi which radiate from the cavities containing the cells and communicate with the Haversian canals. Between the Haversian system are irregularly disposed layers known as ground or interstitial lamellae.

Bone is of **mesodermal** origin and develops chiefly from the **mesenchyme.** The vertebrae, certain bones of the skull, and the long bones are first formed in cartilage which is later replaced by (not transformed into) bone, while others, such as the thin bones of the skull and the bones of the face, are formed directly from mesenchyme; the former are called replacement bones and the latter membrane or dermal bones.

The term bone is also used to designate a single structural unit of the skeletal system. (A.W.L.)

BONGO. Mammalia, Artiodactyla. One of the harnessed **antelopes** or bush-bucks of western Africa. It lives in the forests. *Boöcercus euryceros.* (A.W.L.)

BONITO. Pisces, Teleostei. *Sarda.* Marine fishes (**Pisces**) of several species, related to the mackerel and tuna. (A.W.L.)

BONNER DURCHMUSTERUNG. The name Bonner Durchmusterung is applied to the monumental catalogue of 324,198 stars observed by that tireless observer F. W. A. Argelander. Accompanying the catalogue is an atlas of the heavens upon which each of the catalogued stars is shown by a dot, the size of the dot being proportional to the apparent brightness of the star. The catalogue contains practically every star brighter than the tenth **magnitude** north of **declination** —2°. The catalogue is commonly referred to as the B.D. and in many astronomical writings a particular star is referred to by its B.D. number (i.e., by the number assigned to it in the Bonner Durchmusterung).

The catalogue was continued by Schonfeld down to declination —23°, and Thome at Cordoba has extended it still further to —61°. It is hoped that the plan will be continued to the south pole.

In each of the catalogues stars are numbered in order of increasing **right ascension** within a particular zone of declination. Hence, a star known as CDM —48 1116 is the 1116th star in the Cordoba extension of the BD catalogue between declination —48 and —49. (W.K.G.)

BONTEBOK. Mammalia, Artiodactyla. A small South African **antelope,** *Damaliscus pygargus.* (A.W.L.)

BONY PIKE. Pisces, Holostei. A fish (**Pisces**). The garpike and **gars.** (A.W.L.)

BONY-TAIL. Pisces, Teleostei. A fish (**Pisces**) of the Colorado and Gila rivers, related to the minnows and chubs. *Gila elegans.* (A.W.L.)

BOOK SCORPION. Arachnida, Chelonethida. A European species of pseudoscorpion which is sometimes found in books and papers. (A.W.L.)

BOOK-LOUSE. Insecta, Corrodentia. A small **insect** found in old papers, books and rubbish and in collections of biological specimens. The order to which they belong is a small one containing winged species found on bark and lichens, and wingless species to which this name is applied.

Book-lice must be very numerous to do appreciable damage, and since they frequent damp situations, heating and drying rooms where they are found is usually a simple method of destroying them. Severe infestations can be checked by fumigation. (A.W.L.)

BOOM. A boom is a movable inclined arm of wood or steel used on some types of **cranes** or **derricks** to support the hoisting lines which carry the **loads.** The loads cause direct **compression** in the boom due to the manner in which the hoisting lines are connected to the member.

The word boom also describes a floating chain of logs, which is anchored in such a position in a body of water as to deflect or intercept saw logs, or to prevent floating debris from approaching water intakes to pipe lines, penstocks, etc. Nautically, a boom is a spar holding the foot of a fore and aft sail. (C.W.C., F.T.M.)

BOOMER. Mammalia. 1. The great gray **kangaroo** of Australia, a **marsupial.** 2. The mountain beaver, *Aplodontia,* a species of **rodent** which lives in the forests in the mountain ranges of the Pacific Coast. It is more closely related to the squirrels than to the true beavers. (A.W.L.)

BOOST. Supercharger; Airplane Engine.

BOOSTER. An electrical booster is inserted in series in an **electric circuit,** and increases the **voltage** of that circuit. There are several uses to which the booster can be put. It may be employed to compensate for a line voltage drop, or it may be employed to vary voltage in such a way that constant current is maintained. The boosting of d-c circuits is accomplished by rotating equipment called booster generators. If this booster is driven by an electric motor the set is called a motor-booster. The booster generator can be used to raise the line voltage at a feeder point on an electric traction system.

The booster transformer is sometimes used in **alternating-current circuits.** On a simple single-phase circuit it boosts the line voltage by connecting the primary of the **transformer** across the line, and the secondary in series. There are some disadvantages to this connection, however, since blowing of a fuse, or otherwise open-circuiting the primary, leaves the transformer connected as an open-circuited series transformer, and the open-circuit voltage on the primary winding may be excessive. The **induction regulator** is a form of booster transformer whose effect is varied by rotating one winding with respect to the other.

A mechanical booster is an auxiliary cylinder with which steam locomotives are sometimes equipped. It drives on the trailing truck or on a truck of the tender. The booster installation is used principally on freight locomotives, especially in the mountain sections where the extra tractive power is needed in starting the train. When starting a train from rest the locomotive is obliged to exert a much greater tractive effort than when the train is in motion, because the coefficient of static friction exceeds the coefficient of rolling friction. The booster is used only when starting the train, and is disengaged, usually automatically, when the train speed reaches something like 15 m.p.h. The booster drives through a geared crankshaft to the trailer truck. This extra power is available when starting by virtue of the fact that with a locomotive moving slowly, the main cylinders are not able to use all the steam that can be produced by the boiler. (F.T.M., L.R.Q.)

BOOTES. (The herdsman.) (Map, page 380.) While not in the **zodiac**, Bootes is one of the earliest recorded **constellations.** It is readily recognized in the early summer skies from the kite-shaped configuration of stars with the bright star Arcturus at the position of the tail of the kite.

The star **Arcturus** is the fourth brightest star visible in the northern latitudes. It is also a very interesting star from the astronomical point of view, being what is known as a **giant star.** In appearance the star is a reddish-yellow and the **spectral type** is such as to indicate that its temperature is slightly lower than that of the sun. Its angular diameter has been very carefully determined, and, since its distance is known, we find its linear diameter to be about 27 times that of the sun.

Many of the other brighter stars in Bootes are **double stars,** several of them forming interesting objects of study with relatively small instruments. (W.K.G.)

BORACITE. Boracite is a **borate** of **magnesium** containing some **chlorine.** It appears to be isometric but probably becomes so only at 265° C. below which temperature it is believed to be **orthorhombic.** Its hardness is 7; specific gravity, 2.9; luster, vitreous; color, white to gray, sometimes yellow or green; translucent to subtransparent. It occurs in beds with **gypsum** and salt in Germany, particularly at Stassfurt in Saxony. (E.S.C.S.)

BORAX. Boron.

BORE. The size of a hole in a pulley, gear, or bearing. As a verb, to enlarge and/or accurately finish a hole. (H.C.H.)

BORER. Insecta. Any **insect** which burrows into the tissues of plants. Among the more common pests of this kind are the peach-tree borer, *Synanthedon,* the squash borer, *Melittia satyriniformis,* and the wheat sawfly borer, *Cephus pygmaeus.* In the garden, borers frequently kill young plants by hollowing out the stem and they may even kill larger plants or weaken them so that they break off in the wind. The borers include insects of several orders and various habits, hence it is impossible to suggest general methods of treatment. A knowledge of the habits of the insect, particularly of the time of year when the eggs are laid or when the larvae enter the plants, is important since at other times the insect is beyond reach. In the home garden the hole made by the insect on entering the stem is often readily visible and by slitting the stem the invader can be found and killed, but unfortunately the weakening of the plant is the first indication of trouble. A little pyrethrum or rotenone powder introduced into the burrow will also prevent further damage. (A.W.L.)

BORING. The process of enlarging and/or accurately finishing a hole, usually with a single-point tool. Contrast **drilling, reaming, trepanning.** Boring may be effected on a **lathe** by a suitable tool held in the tool post; the work may be held in a chuck, clamped to the lathe faceplate, or mounted on the base of the cross-slide after the compound rest and cross-slide proper have been removed. In such cases, the boring tool is carried in a boring bar which is swung between the lathe centers and driven by a lathe dog.

For work of any variety either boring mills or boring machines are used. A boring mill is essentially a lathe set on end, and has a rotating horizontal table which is driven by a vertical spindle. Single-point cutting tools are carried in tool heads on rams that may be adjusted and fed vertically, and may be positioned or fed along a supporting cross-rail.

There are two important types of boring machines: those with a horizontal spindle, and those with a vertical spindle. Horizontal-spindle boring machines for large work are built with a base or floor plate level with the floor of the shop. Table-type horizontal-spindle boring machines have a table which is mounted on a saddle. Both the table and saddle are equipped with power feed and rapid traverse movements; the table moves on the saddle, in a direction perpendicular to the spindle, and the saddle moves parallel to the spindle, on the bed. The spindle rotates in the spindle head which may be power adjusted or fed along the vertical face of the column.

Boring, drilling and milling operations may be performed on horizontal-spindle boring machines. Milling cutters may be held in the spindle socket, or bolted directly to the spindle flange. Boring is handled with piloted bars whenever possible, but boring tools may be held in an adjustable boring head.

The vertical-spindle boring machine or **jig borer** is widely used for boring holes in jigs, fixtures, and dies, and has almost entirely replaced toolmakers' buttons or disks for accurate hole location.

Wash borings are frequently used to examine the subsurface formations in connection with deep **foundation** work. The equipment consists of a hollow pipe called a jet pipe and a larger hollow pipe called a casing. Water under pressure is forced down the jet pipe. This water washes the disintegrated material up through the space between the jet pipe and the casing to the surface where it may be retained for future examination. As the material at the bottom of the casing is washed away the casing is slowly forced downward. Where the precise character and formation of subsurface rock formations must be known, as in the case of foundations for important dams, core boring (sometimes called core drilling) is usually a necessity. A core drill consists of a hollow cylindrical bit with its cutting edge set with hard cutting particles (such as commercial diamond particles) connected to a hollow cylindrical drill shank. The whole is rotated by mechanical power and thus cuts out a vertical, or inclined, cylinder of the rock. These cores are periodically removed and when re-assembled constitute a clear and visible section of the rock structures pierced. (H.C.H., C.W.C., E.W.S.)

BORNEOL. Alcohols and Ethers.

BORNITE (Peacock Ore) (Horse-Flesh Ore). Named for the German mineralogist of the 18th century, Ignatius von Born, this mineral is a **sulfide** of **copper** and **iron** corresponding to the formula Cu_5FeS_4. It is **isometric** with a cubic habit, although crystals are rare, usually occurring as granular or compact masses. Its fracture is conchoidal to uneven; brittle; hardness, 3; specific gravity, 4.9–5.4; color, copper-red to reddish-brown (hence the name horse-flesh ore) when freshly fractured; it soon assumes an iridescent tarnish (hence the name peacock ore); luster, metallic; streak, grayish-black; opaque.

Bornite as a primary mineral has been observed in

pegmatite veins and in **igneous rocks** and is also a common secondary mineral.

Bornite crystals have been obtained in Austria and England. As an ore it is important in Tasmania, Chile, Peru and in Montana. Bornite has been found in Connecticut and in the Province of Quebec. (E.S.C.S.)

BORON. Symbol: B. Atomic number: 5. Atomic weight. 10.82. Density: 2.54 (for the crystalline form), 2.45 (for the amorphous form). Hardness: 9.5 (for the crystalline form). Melting point: 2300° C. Boiling point: 2550° C. Isotopes: 10 (20%), and 11 (80%).

Boron is (1) a yellowish-brown crystalline solid, (2) an amorphous greenish-brown powder. Both forms are unaffected by air at ordinary temperatures but when heated to high temperatures in air form oxide and nitride. Crystalline boron is unattacked by **hydrochloric** or **nitric acid**, or by **sodium** hydroxide solution, but with fused sodium hydroxide forms sodium borate and **hydrogen**; reacts with **magnesium** but not with **sodium**. Discovered by Davy and by Gay-Lussac and Thenard in 1808.

Boron occurs as **rasorite** or kernite (sodium tetraborate tetrahydrate, $Na_2B_4O_7 \cdot 4H_2O$) and **colemanite** (calcium borate, $Ca_2B_6O_{11} \cdot 5H_2O$) in California, as **sassolite** (boric acid, H_3BO_3) in Tuscany, Italy, and also locally in Chile, Turkey, and Tibet. The borates are transformed to boric acid, which is heated to form the oxide, and this last reduced to boron by ignition with **aluminum** powder. The aluminum is then dissolved by hydrochloric acid or sodium hydroxide solution, leaving boron residue.

Acids: Boric acid (ortho H_3BO_3 or $B_2O_3 \cdot 3H_2O$; pyro or tetra $H_2B_4O_7$ or $2B_2O_3 \cdot H_2O$; meta HBO_2 or $B_2O_3 \cdot H_2O$), white solid, soft and smooth to the touch, moderately soluble in the cold but very soluble in the hot, made by reaction of solution of a borate and hydrochloric, nitric, or sulfuric acid of proper concentrations, forms boron oxide glass upon ignition, forms borates by precipitation reactions or by fusion methods, used as an antiseptic, and in cosmetics and skin powders; hydrofluoboric acid (HBF_4), colorless solution, by reaction of boron fluoride with **hydrofluoric acid** solution forms fluoborates by neutralization method.

Borates: Sodium tetraborate, borax ($Na_2B_4O_7 \cdot 10H_2O$), white solid, soluble, used (1) in soaps and laundry starch glazes, (2) in ceramic glazes and enamels, and special glasses, (3) in metallurgical **fluxes**, (4) as source of boron-containing substances; **calcium** borate, white solid, insoluble; **silver** borate ($AgBO_2$), white precipitate, by reaction of borate solution and silver nitrate solution (silver oxide, brown solid, may accompany in this reaction); potassium fluoborate (KBF_4), white solid, moderately soluble, by reaction of hydrofluoboric acid and **potassium** carbonate, and then crystallizing; sodium perborate ($NaBO_3$), white precipitate, by reaction of sodium borate solution and **hydrogen peroxide**, used (1) as germicide and antiseptic, (2) as oxidizing and bleaching agent, (3) in cosmetics and soaps; methyl borate, and ethyl borate, see below.

Borides: Carbon boride (CB_6) and silicon borides (SiB_3 and SiB_6) are hard, crystalline solids, produced in the electric furnace; magnesium boride (Mg_3B_2), brown solid, by reaction of boron oxide and magnesium powder ignited, forms boron hydrides with hydrochloric acid; calcium boride (Ca_3B_2), forms boron hydrides and hydrogen gas with hydrochloric acid.

Chloride: Boron chloride (BCl_3), colorless fuming liquid, by reaction of boron, or boron oxide plus carbon, heated with **chlorine**, boiling point 12.5° C.

Fluoride: Boron fluoride, boron trifluoride (BF_3), colorless gas, by reaction of boron oxide, **calcium** fluoride and hot concentrated **sulfuric acid**; reacts with water to form boric acid plus hydrofluoric acid, and the latter, with excess boron fluoride, forms hydrofluoboric acid; combines with ammonia (e.g., $BF_3 \cdot NH_3$).

Fluoborate: Potassium fluoborate (KBF_4), white solid, slightly soluble, decomposed upon heating to 500° C.

Hydrides: Tetraboron hydride, tetraborane, borobutane (B_4H_{10}), colorless liquid 16° C., by reaction of **magnesium** boride and **hydrochloric acid**, followed by fractional purification of the gas; tetraboron hydride is the best known hydride; others lower and higher in the series are known.

Nitride: Boron nitride (BN), white solid, insoluble, reacts with steam to form **ammonia** and boric acid, formed by heating anhydrous sodium borate with **ammonium** chloride, or by burning boron in air.

Oxide: Boron oxide, boron trioxide, boric acid anhydride (B_2O_3), white, glassy solid, reactive with water to form boric acid and used as a dehydrating agent, melting point about 575°C., formed by heating boric acid to high temperature with loss of water, used as a nonvolatile acidic oxide.

Sulfide: Boron sulfide (B_2S_3), white solid, unpleasant odor, irritating to the eyes, reactive with water to form boric acid and hydrogen sulfide, formed by reaction of boron oxide plus carbon heated in a current of **carbon disulfide** at red heat.

Organic compounds: Methyl borate, trimethoxy boron ($B(OCH_3)_3$), colorless liquid, boiling point 65° C., by reaction of boric acid, even in very dilute solution, and methyl alcohol, and recognized by the green color of the flame when ignited; ethyl borate, triethoxy boron ($B(OC_2H_5)_3$), colorless liquid, boiling point 120° C., by reaction of boric acid, even in very dilute solution, and ethyl alcohol, and recognized by the green color of the flame when ignited.

Boron trimethyl ($B(CH_3)_3$) is a colorless gas; boron triethyl ($B(C_2H_5)_3$), a colorless liquid, boiling point 95° C.; boron diethyl dihydroxyl ($(C_2H_5)_2B(OH)_2$), sublimes at 40° C.

Borate solution when slightly acidified, or dilute boric acid solution imparts a characteristic reddish color to turmeric paper, intensified upon drying, and turned a characteristic bluish color upon moistening with ammonium hydroxide.

When borates are treated in a porcelain dish with methyl alcohol and concentrated sulfuric acid, the mixture stirred and ignited, a green-bordered flame will appear. (R.K.S.)

BORROW PIT. The section of ground from which earth is excavated for the purpose of being used as fill at some other point is called a borrow pit. Borrow pits are used extensively in connection with highway construction since it is often more economical to obtain fill from some nearby source than to carry it from some distant point along the line where there is an excess of cut. When it is necessary to ascertain the amount of material taken from a borrow pit the ground surface is divided into rectangles or squares before any material has been removed. This grid system is referred to an arbitrary **base line** and elevations are taken on each of the corners. After the required material has been removed the system of rectangles or squares is reproduced by means of the base line and elevations are again taken on the corners. The volume of material which has been excavated then consists of the sum of the volumes of the individual prisms. (C.W.C.)

BORT or BOART. Diamond.

BOSS. The term boss or stock is used to indicate a cross-cutting mass of **igneous rock** which has ascended into the crust of the earth and may or may not represent the roots of volcanic conduits. Bosses are roughly circular or elliptical in ground plan and usually of greater cross-sectional area than a volcanic neck and lack **pyroclastic** materials. Most probably bosses are the irregular upward extensions of **batholiths** the main parts of which are as yet unexposed.

Boss also designates a circular projection on a casting, usually serving as the seat for a bolt head or nut. (R.M.F., H.C.H.)

BOSTONITE. A rather rare rock type, dense, with an occasional feldspar **phenocryst** and grayish in color. It is composed almost wholly of alkaline feldspar, being analogous to **aplites.** The type locality is Salem Neck, Massachusetts, not many miles from Boston, for which it was named. (E.S.C.S.)

BOT FLY. Insecta, Diptera. **Flies** of two families whose larvae live as internal parasites in mammals. The adults as a rule have vestigial mouth parts and attack the host only to deposit their eggs.

Horses are attacked by two species of bot flies of the genus **Gastrophilus.** One deposits its eggs on the lips, whence the **larvae** reach the throat or stomach, and the other attaches them to the hairs of the forelegs, where they die unless the horse takes the larvae into its mouth by licking or biting the legs. The larvae develop in the alimentary tract and pass out when mature with the feces. These flies belong to the family Gastrophilidae.

The sheep bot adult, *Oestrus ovis,* deposits living larvae in the nostrils of the host, whence they work their way into the sinuses, into the horns, and even into the brain. Two other species known as **warble-flies** lay their eggs on the hairs and the young larvae migrate through the skin and ultimately to the **oesophagus.** Later they migrate again through the connective tissue to the back, where they complete their development in subcutaneous abscesses which produce the external lumps known as warbles. The skin over the abscess is perforated and the larva leaves its host and drops to the ground to pupate. These species make up the family Oestridae, together with numerous others which attack wild animals (A.W.L.)

BOTANY. Botany is the science which deals with plants. It is divided into many sections, each dealing with a specific part of the subject. One section, which describes plants and arranges them in classes, is called taxonomy; another section, morphology, considers the form of the various parts of a plant, while its subsections include anatomy and histology, the study of the internal structure of plants, and cytology, the study of the cell and its parts. A third, physiology, deals with the functions of the parts. In addition, one may study plant geography, or the distribution of plants on the earth; ecology, the relations of plants to each other and to their environment; phytopathology, or the diseases of plants; paleobotany, the science of fossil plants; and economic botany, which considers the uses which man has found for plants and plant products.

The science of botany is very old. Since the welfare of man is closely connected with plants, it is natural that they should receive attention early. Undoubtedly plants were known and observed by men long before the period of Greek supremacy. Various recorded observations suggest that such is true. But only with the intellectual curiosity of the Greek mind do plants receive close attention. Aristotle (384–322 B.C.) studied them attentively and cultivated many species from widely separated regions. His disciple Theophrastus (371–287 B.C.) carried on the work and wrote about them in his "Enquiry into Plants," in which he describes some five hundred species and gives extensive and keen observations concerning them. In Rome another naturalist, Pliny the Elder (23–79 A.D.), writes extensively on Natural History, setting forth information on some thousand species of plants. His facts are largely drawn from sources other than the plants themselves and are often grossly exaggerated. His Natural History was of immense importance, however, and largely controlled the thought of botanists for many centuries. Another ancient naturalist, Dioscorides, also studied plants. He was mainly interested in them because of the important place they held in the medical practice of that time. Indeed, the study of plants was for a long period of time considered the province of physicians and doctors, whose main interest was in plants as remedies or supposed remedies for various ills. After this, centuries followed in which little attention was given to plants; all knowledge thereof was drawn directly from the works of the ancient writers.

Beginning with the 16th century, however, interest in plants was revived. Men began observing the native plants around them and recording these observations, often accompanied by illustrations, in herb books or herbals. Such observations led to attempts to arrange and classify the various plants. Among the first herbals were those of Brunfels (1530) and Fuchs (1542), both of them containing excellent illustrations, but relying for their descriptions largely on the ancient writers of Greece and Rome. Hieronymus Bock (1498–1554) was another herbalist, who gave in his book extensive first-hand descriptions of the plants which he treats. William Turner and John Gerard published herbals treating of English plants. Valerius Cordus (1515–1544) gave even more complete and accurate descriptions of the plants in his books than Bock.

As a result of the work of these men and many others, came a need for a better understanding of plants and the necessity for arranging them in some sort of system other than that of size or of the alphabet. John Ray (1628–1705) advanced the problem considerably by introducing an exact concept of species, which he held to come from a single parent and to continue to produce like organisms, although he does allow some variation to occur. Ray separated flowerless plants from flowering, and divided the latter into **Dicotyledons,** with two seed leaves, and **Monocotyledons,** with only one.

The number of plants described was constantly increasing, rendering even more necessary a system of arranging them in order. Many systems were proposed, some having great merit. As early as 1583 Casalpino had eliminated any classification based on such variable organs as roots, stems or leaves, and had concluded that the flowers and fruit offered the only real basis. It remained for Carolus Linnaeus (1707–1778) to bring order to the situation. He invented the binomial system of nomenclature, by which each plant (and animal also) should be known by a name designating the genus and a qualifying adjective limiting the species named. His system of classification was purely artificial, being based on the number of stamens and pistils (see **Flower**), but did make it easy to refer to a description and so verify an identification. He also grouped plants and animals in larger divisions, the classes and orders. The present-day names of plants date from the time of Linnaeus. It has long been recognized that there seemed to be a natural grouping of plants; John Ray apparently understood some of the larger groups of plants. With the work of the French taxonomist A. L. de Jussieu came a definite knowledge of the natural relations of plants, which he grouped into fifteen classes with about a hundred orders.

While classification and description occupied a large place in the development of botany, other branches of the science were not neglected, although of necessity many of them waited on advancement in taxonomy. The anatomy of plants was studied by Nehemiah Grew (1641–1712) in England, and Marcello Malpighi (1628–1684) in Italy, while casual observations on the internal structures of some plant substances were made by Robert Hook. The finely illustrated writings of these men established the foundations for an understanding of the internal structure of plants. Subsequent workers in this field showed the similarities existent in the internal structures of plants, and the changes which have oc-

curred during the evolution of plants. Out of this have come the later studies of cytology and histology.

Any knowledge of the way in which the plant lives and the functions of its various parts was slow to develop. The lack of definite organs connected with such functions as digestion, circulation, respiration, etc., made the problem even more difficult. Occasional observations had been made from time to time, often leading to erroneous conclusions. With Stephen Hales (1677–1761) plant physiology became established. He first used instruments to measure various physiological activities which he studied. His observations, recorded in his "Vegetable Staticks," published in 1727, show how attentively he studied the problem of nutrition in plants and the movements of liquids within the plant. Ingen-Housz (1730–1799) gained more exact knowledge of the problem of nutrition in plants, definitely showing that the **carbon** in plants came from the **carbon dioxide** of the atmosphere. He had an accurate knowledge of the role of gases in the life of the plant. Another worker, Andrew Knight (1758–1838), studied an entirely different field, being largely interested in the problem of direction of growth of root and stem. To him is due the use of a rapidly revolving wheel to which seedlings were attached. From this experiment he determined that roots grew away from the center of the revolving wheel and stems towards the center. Out of his studies came the study of tropisms (see **Movements in Plants**) in general. At the present time the study of physiology of plants is one of the most important and most fascinating, engaging the attention of many workers.

However, other branches of the science of botany have not been overlooked. The study of the distribution of plants has been pursued with great vigor, bringing to light many interesting problems, at times difficult to explain. Why should certain similar groups of plants appear in widely separated regions? At present this and many other questions are subjects for speculation and cause for further study.

Another branch of botany which occupies an important position today is that of plant pathology, which treats of the diseases of plants. When a single disease such as **wheat rust**, attacking a single crop, causes the loss of millions of dollars in reduced harvests, and with so many crops subject to numerous diseases, this must be recognized as a study of vital importance to man. Comprehensive and exact knowledge of the disease-producing organism is necessary. Often it is obtained only after prolonged, painstaking study. Then follows the problem of treatment leading to elimination of the disease, a study in itself. Sometimes this is impracticable; it is quicker to attack the problem in another way—to attempt to develop strains of plants which are resistant or immune to the disease. In this field new problems are constantly arising, or assuming greater importance, as for example was the case in the outbreak of the Dutch Elm Disease in recent years, or of the Chestnut Blight disease which so nearly wiped out the chestnut trees of America a few years ago.

These and many other problems show how close is the welfare of mankind tied up with the study of botany and the knowledge of the many sides of that science. (R.M.W.)

BOTHRIOLEPIS. **Fossil Fishes.**

BOTHRIUM. A projecting or grooved structure which takes the place of a sucker on the **scolex** of some **leeches.** (A.W.L.)

BOTRYOIDAL TISSUE. A peculiar kind of pigmented **tissue** with **cells** arranged end to end and containing intracellular capillaries filled with red liquid, found in **leeches.** (A.W.L.)

BOTULISM. A type of food poisoning resulting from the ingestion of toxins of *Clostridium botulinum*, a species of **anaerobic bacteria.** These organisms are gas-forming bacilli which grow in sealed or canned food. Commercially canned products formerly caused outbreaks but, since proper sterilization by heat has been employed by packers, commercial products have been safe. In recent years, it has been the home canned foods which are improperly sterilized and therefore contain the resistant **spores** of the organism which cause botulism.

The symptoms of poisoning appear 18 to 36 hours after eating spoiled food. The toxin has a special affinity for the nervous system. Double vision, difficulty in swallowing and speaking, are the most prominent features. Nausea and vomiting occur in only one third of the cases. The mortality rate is high—about 66%; death is usually due to respiratory paralysis. Treatment is with specific antiserum containing an antitoxin to neutralize the effects of the bacterial toxin. (D.M.H.)

BOUGAINVILLAEA. Nyctaginaceae. A small genus of plants, natives of South America, which are frequently cultivated in the tropics and to some extent as greenhouse plants outside the tropics. The flowers of the plants are small and inconspicuous, but are surrounded by showy bracts of various colors. The plants are generally grown for these brilliant-colored **bracts.** One species, *Bougainvillaea spectabilis*, is a clambering vine which is often grown in cultivation. (R.M.W.)

BOULANGERITE. A mineral compound of lead-antimony sulfide, $Pb_5Sb_4S_{11}$. Crystallizes in the monoclinic system; hardness, 2.5–3; specific gravity, 6.23; color, lead gray. (R.M.F.)

BOULDER. A large fragment of rock, usually rounded, which has been moved from its place of origin by a natural agency or has been formed in situ by weathering processes. Rather arbitrarily, 8″ has been set as the minimum diameter for a boulder. (E.S.C.S.)

BOULDER CLAY. Boulder clay is a glacial deposit of clay with subangular rock fragments of different sizes. (E.S.C.S.)

BOULDER TRAIN. Erratic.

BOUNDARY LAYER, FLUID FLOW. Motion of a fluid of low viscosity, such as air or water, around a stationary body or through a stationary conduit possesses the free velocity of an ideal fluid everywhere except in an extremely thin layer immediately next to the stationary body. Many of the phenomena of fluid flow may be studied and analyzed without consideration of this boundary layer, but, thin as it may be (usually a few thousandths of an inch), its internal mechanics must be understood and evaluated in certain of the phenomena of fluid motion. Some of the more important of these are:

1. The magnitude of the maximum lift coefficient of the airfoils.
2. Profile drag of airfoils.
3. The drag of bluff bodies.
4. The large variations of drag coefficient at critical Reynolds number for laminar-turbulent transition.
5. The transfer of heat through surface films.

Many of the phenomena of the boundary layer are explainable on the basis of the theory advanced by Prandtl at the great University of Göttingen laboratory nearly half a century ago. In the same flow-research group were others, like Blasius, who broadened and experimentally confirmed the original hypotheses.

An elementary understanding of the effect of fluid viscosity will be had by considering a two-dimensional flow along the upper surface of a very thin flat-plate, as shown in Fig. 1. The thickness of the boundary layer, greatly exaggerated, is y_v; the free stream velocity is V, the variable velocity in the boundary layer is u.

A basic assumption of the theory is that a fluid layer of infinitesimal thickness resting against the plate "sticks" to it so shearing force of the next fluid layer on the sta-

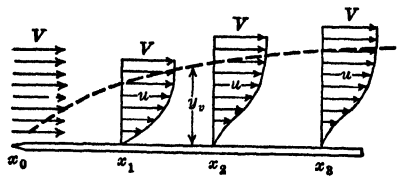


Fig. 1 Velocity profiles in the boundary layer (dotted line is hypothetical upper edge of the boundary layer).

tionary layer determines the skin friction. Assuming that the boundary layer consists of lamina of fluid sliding on each other, the velocities of these lamina increase with y until, at the edge of the boundary layer, $u = V$. A series of boundary layer velocity profiles for stations x_1, x_2, x_3 are drawn to enable the reader to visualize the effect of friction on the momentum in the boundary layer and the thickening of it due to lower average u.

Note also the variation of the profile near the surface of the plate. Skin friction has steadily decelerated the individual fluid particles. The profile at x_3 indicates that the lower portion has come to rest. This is known as the stagnation point. Air-flow phenomena in this region are important in many ways, especially when there is an intended rising downstream pressure gradient, as in diffuser tubes or over the surface of airfoils.

Fluid flow in a divergent tube is illustrated in Fig. 2. On the lower profile, greatly enlarged velocity profiles are

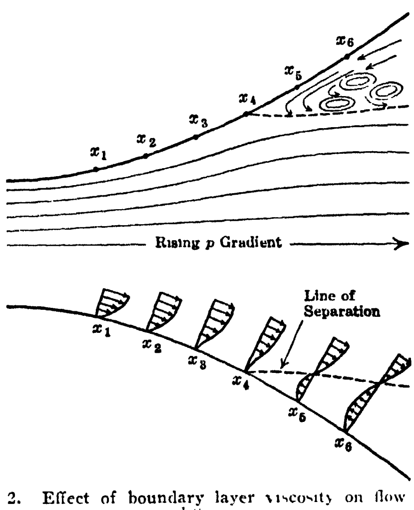

Fig. 2. Effect of boundary layer viscosity on flow on a diffusor.

shown for the boundary layer at stations x_1, x_2, $\cdots x_6$. The x_4 profile indicates a stagnation point. Since the pressure gradient of the diffuser has a pressure at x_5 above that at x_4, a reverse flow is produced towards the stagnation point. Streamlines drawn in the upper half of the tube show what happens to the fluid flow. The region of the surface of separation between the reverse flow along the wall and the forward flow is unstable and breaks up into random vortices. Kinetic energy is irreversibly transferred to heat and the diffusion fails to produce the expected pressure gradient. Had the divergence of the conduit been sufficiently small, the pressure gradient would have been lowered per unit length and turbulence in free stream or boundary layer would have delayed the stagnation point.

For the airfoil with burbled or partly burbled air flow (Fig. 3), a similar explanation exists. Streamline flow over the upper surface of the airfoil increases in velocity as angle of attack (and **circulation** Γ) increases. However, the surface friction in the boundary layer is decelerating the air particles next to the surface

Fig. 3. Partial burble on airfoil at high angle of attack. A—Stagnation point. B—Line of separation.

and with high adverse pressure gradient (existing at high angle of attack) opposing the kinetic energy of the boundary layer the velocity profiles ultimately show a stagnation point toward the rear of the airfoil. The flow separates from the surface and vortices form a turbulent wake in place of the streamline wake previously existing. Once the separation surface moves onto an airfoil, minor increases of angle of attack bring it rapidly forward. High circulation strength is no longer needed to fulfill the requirement of unity of upper and lower flows at the trailing edge (Kutta's hypothesis) so Γ decreases sharply, and with it the lift. Boundary layer theory accounts in this manner for the maximum lift coefficient. At the same time the extended turbulent wake sharply increases the profile drag coefficient.

Now return to a view of the nature of flow in the boundary layer. It has been called laminar, and so it is for values of **Reynolds number** below a *critical* value. But for years, beginning about the time of Osborne Reynolds' experiments and revelations in the field of fluid flow, it has been known that the laminar property disappears and the flow suddenly becomes turbulent when the critical $\frac{Vl}{\nu}$ is reached. Usually flow starts over a surface as laminar but after passing over a suitable length the boundary layer becomes turbulent, with

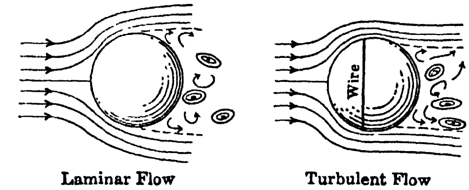

Fig. 4. Boundary layer turbulence reduces width of low-pressure wake.

a thin laminar sublayer thought to exist because of damping of normal turbulent components at the surface.

This transition has profound effects in all fluid dynamics, and certainly so in aerodynamics. The velocity profile in the boundary layer becomes fuller near the surface on account of the higher average kinetic energy of the layer created by turbulent energy exchange from layer to layer. The effective viscosity is therefore larger in turbulent than laminar flow, the turbulent boundary layer thickens more rapidly downstream, and skin friction increases.

The importance to aerodynamics is the beneficial effect of turbulence on the wake existing in the rear of **bluff bodies.** Even thin airfoils become bluff bodies at high angles of attack. A turbulent boundary layer has more kinetic energy than a laminar one. This carries the air farther toward the rear of the surface before a **stagnation point** is reached and so reduces the width of the wake and that part of the profile drag. This reduction of drag can be, and usually is, much larger than the increase of skin friction so turbulence has a good effect on both profile drag and maximum lift coefficient of an airfoil. The critical value of Reynolds number lies between 200,000 and 2,000,000, being affected by the initial turbulence existing in the air prior

to meeting the surface. Decreasing initial turbulence increases the critical Reynolds number. The effect of turbulence on the boundary layer is strikingly displayed by observing the drag wake behind a smooth sphere mounted in an airstream whose velocity is just under that required to produce breakdown of the laminar boundary layer. An artificial roughness is provided in the form of a fine wire or thread encircling the sphere in the laminar flow. The boundary layer, of course, becomes turbulent downstream from this irregularity resulting in a delayed stagnation point and narrower wake. (F.T.M.)

BOUQUETIN. Ibex.

BOURNONITE (WHEEL ORE). An **antimony-copper-lead sulfide** corresponding to the formula $2PbS \cdot Cu_2S \cdot Sb_2S_3$. It is **orthorhombic,** and repeated twinning often produces crosses or wheel-shaped crystals. It is brittle; fracture, sub-conchoidal; hardness, 2.5–3; specific gravity, 5.7–5.9; luster, metallic; color and streak, dark gray to black; opaque.

Bournonite is found with **galena, chalcopyrite, sphalerite,** etc. There are many European localities; it was first found in Cornwall, England, by Count Bournon, for whom it was later named. Bournonite occurs in Bolivia and Peru and in the United States in Arizona, Montana, Nevada and Utah. (E.S.C.S.)

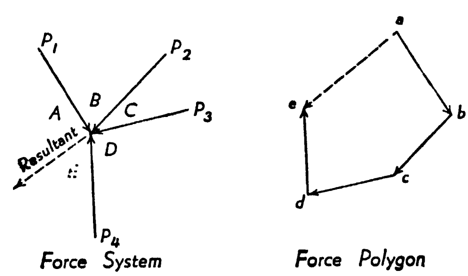
BOUTO. Dolphin.

BOWER-BIRD. Aves, Passeriformes. Birds (**Aves**) of several species found in the Australian region. They build runs roofed with grass or sticks and decorated with bright articles of all kinds. (A.W.L.)

BOWFIN. Pisces, Holostei. A species of fish (**Pisces**), *Amia calva,* found in lakes and sluggish streams in the eastern and central United States. Related to the gars and, like them, not valuable for food. Also called the dogfish. (A.W.L.)

BOWMAN'S CAPSULE. Renal Corpuscle.

BOW'S NOTATION. Bow's notation is a standard method of representing, by letters of the alphabet, forces and **stresses** in graphical analysis. This analysis may consist of such problems as the graphical solution of stresses in simple framed structures or the determination of the **resultant** of an independent system of unbalanced forces lying in the same plane and having a common point of application. The accompanying figure illustrates the method of applying Bow's Notation to the latter system. Let P_1, P_2, P_3 and P_4 be a system of unbalanced forces lying in the same plane and having a common point of application. Denote the space between the line of action of each force by the letters *A, B, C* and *D.* Next construct a figure called a force polygon. This is accomplished by drawing a line parallel to P_1 and laying off its magnitude to a definite scale denoting the ends of the line by the letters *a* and *b.* **From point *b*** lay off *bc* equal in magnitude and parallel to P_2. Repeat the operation for the other forces. Upon completion of this graphical figure it will be found, in general, that the line representing P_4 will not pass through point *a.* The distance from point *a* to end of this line, which will be lettered *e,* represents the value of the resultant of P_1, P_2, P_3 and P_4 according to the scale used. The direction of *ae* determines the line of action of the resultant. Thus, in Bow's Notation a force in space is designated by the space letters on either side of it, whereas the forces as part of the force polygon are named by the letters at their extremities. This notation is further illustrated in the accompanying figure. (C.W.C.)



BOX TOOL. A tool with tangentially-cutting blades and a supporting rest, used on automatic screw machines. (H.C.H.)

BOX WRENCH. Wrenches.

BOXWOOD. *Buxus sempervirens. B. balearica.* Slow-growing trees or shrubs often planted for ornament because of their dark thick smooth leaves and compact habit. They are tender plants which must be treated as greenhouse subjects in cold climates. *B. balearica* is a tree growing to a height of 75′ or more. From it is obtained a dense yellow wood having a very close fine grain. This wood is used in wood engraving, in the manufacture of rulers and of musical instruments, and in inlay work. (R.M.W.)

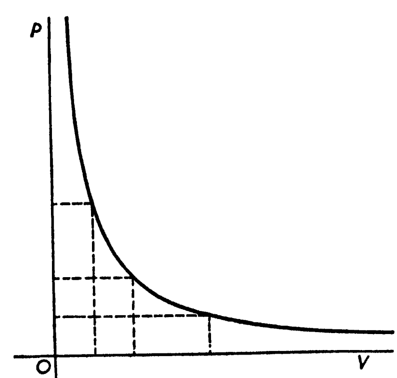
BOYLE-CHARLES LAW. Boyle's law expresses the variation of pressure and volume of a body of ideal **gas** at constant temperature; Charles' law expresses the proportionality of pressure to absolute temperature (at constant volume), while Gay-Lussac's law states the proportionality of volume to absolute temperature (at constant pressure).

A single statement covering all these relationships is the Boyle-Charles law, which leads to, or is a form of, the **ideal gas law.** Its mathematical expression may be written:

$$pv = p_0v_0(1 + at),$$

in which p_0v_0 is the value of pv at temperature $t = 0$, and a is the volume coefficient of expansion for the gas in question. If the centigrade scale is used, a is for all gases approximately equal to $1/273$ or 0.003663 per centigrade degree. (L.D.W.)

BOYLE'S LAW. This well-known law, attributed to Robert Boyle (1662) but also known as Mariotte's law, expresses the **isothermal** pressure-volume relation for a body of ideal gas. That is, if the gas is kept at constant temperature, the pressure and volume are in inverse proportion, or have a constant product. The law is only approximately true, even for such gases as hydrogen and helium; nevertheless it is very useful. Graphically, it is



Equilateral hyperbola representing Boyle's law. The rectangular areas (pv) are all equal.

represented by an equilateral hyperbola. If the temperature is not constant, the behavior of the ideal gas must be expressed by the **Boyle-Charles law** or by the **ideal gas law.** (See **Characteristic Equation.**) (L.D.W.)

BRACHIAL. Pertaining to the arm, from the Latin term *brachium*. (A.W.L.)

BRACHIATION. Locomotion.

BRACHIOPODA. A phylum of marine animals which resemble the **bivalve** mollusks superficially. In the remote past they were much more abundant, as is shown by extensive fossil remains of many more forms than exist today.

The brachiopods are characterized by the following structures: 1. The body is enclosed by a shell consisting of dorsal and ventral valves. 2. The animal is **triploblastic** and coelomate but not segmented. 3. A **ciliated** organ called the **lophophore** projects about the mouth. It maintains currents of water which carry food and oxygen to the animal and wash the wastes away.

The phylum is divided into two orders:

Order Ecardines. Valves of shell not joined by a hinge. Anus present.

Order Testicardines. Valves of shell joined by a hinge. Alimentary tract without an anus.

(See also **Invertebrate Paleontology.**) (A.W.L.)

BRACHIOSAURUS. Fossil Reptiles.

BRACHYBLAST (OR SHORT SHOOT). In many plants, especially in the **Gymnosperms,** the display of leaves to light is considerably advanced by the formation of short lateral branches called brachyblasts. In the **larch** this short shoot is well developed. In this plant it persists, year after year, bearing at its tip a small group of leaves. It does not, however, increase in diameter even after several years of growth. The brachyblast develops from a bud formed in the axil of a leaf. The **maidenhair tree** or *Ginkgo* is another tree having well-developed short shoots. In both these plants and in many others the short shoot bears at its tip a terminal bud from which the leaves of the following year develop. In the **pines,** on the contrary, the short shoot is very much reduced and bears no terminal bud. In these plants the short shoot is reduced to a single bundle of leaves which persist for a year or two and then drop off completely. That this condition in pines is a reduced condition is clear from the condition found in fossil pines, which have a well-developed brachyblast, bearing many leaves and having a terminal bud. (R.M.W.)

BRACHYCEPHALIC. Short-headed. As applied to measurement of the human skull, with a width which is more than 4/5 of the length. (A.W.L.)

BRACKELSBERG FURNACE. A horizontal rotating coal- or oil-fired melting furnace used principally for gray and white **cast iron.** (R.H.H.)

BRACKET FUNGI. Polyporaceae (also called Shelf fungi). A large group of **fungi** the fruit-body of which forms a characteristic shelf-like outgrowth from the trunks of trees. This fruit-body arises from a mycelium of fine hyphae, which penetrate throughout the woody tissue of the host plant, from which they derive nourishment and which they slowly destroy. The fruit-bodies are often perennial, showing on sectioning the successive growth-layers, which are added each year. (See **Basidiomycetes.**) (R.M.W.)

BRACT. In many flowering plants there is found at the base of the flower stalk a small leaf, often considerably modified: this is called a bract. In many plants its minute size causes it to be overlooked; in others it is a conspicuous object. In the Poinsettia, for example, the large showy red "flower" is really composed of bracts, as also is the conspicuous white petal-like structure surrounding the very small flowers of the Flowering Dogwood. (R.M.W.)

BRAGG'S LAW. The law expressing the condition under which a **crystal** will reflect a beam of **x-rays** with maximum distinctness, at the same time giving the angle at which the reflection takes place. For x-ray reflection it is customary to use the complement of the angle of incidence and reflection, that is, the angle which the incident or the reflected beam makes with the crystal planes, rather than with the normal. Let this "Bragg angle" be θ. If the planes or layers of atoms are spaced at a distance d apart, and if λ is the wavelength of the x-rays, Bragg's law is expressed by the equation

$$\sin \theta = \frac{n\lambda}{2d}.$$

The condition for an intensity maximum is that n must be a whole number. For example if the planes of rock salt parallel to the natural cubical faces are spaced at $d = 2.814 \times 10^{-8}$ cm. or 2814 x-units, and if the incident rays have a component of wavelength $\lambda = 714$ x-units, the above equation gives $\sin \theta = 0.1269n$. Then if the crystal is rotated slowly, there will be a distinct reflection when θ reaches $7° 17'$ ($n = 1$), again at $14° 42'$ ($n = 2$), also at $22° 23'$ ($n = 3$), etc. (L.D.W.)

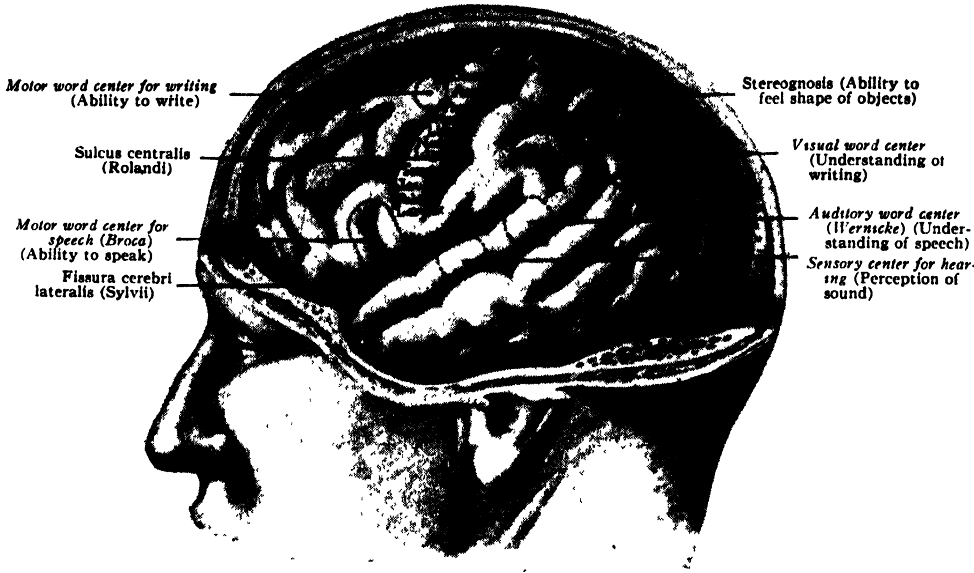
BRAIN. The principal central organ of the **nervous system,** consisting of a mass of nervous tissue lying in the head or in an equivalent position in animals which have no head.

A true brain appears only in bilaterally symmetrical animals. In its simplest form it is relatively small and is known also as the cerebral **ganglion.** Such a brain occurs in the **worms.** In **cephalopod** mollusks and in some of the **arthropods** the brain is larger and more complex but in no invertebrates does it attain the degree of development which is found in the vertebrates.

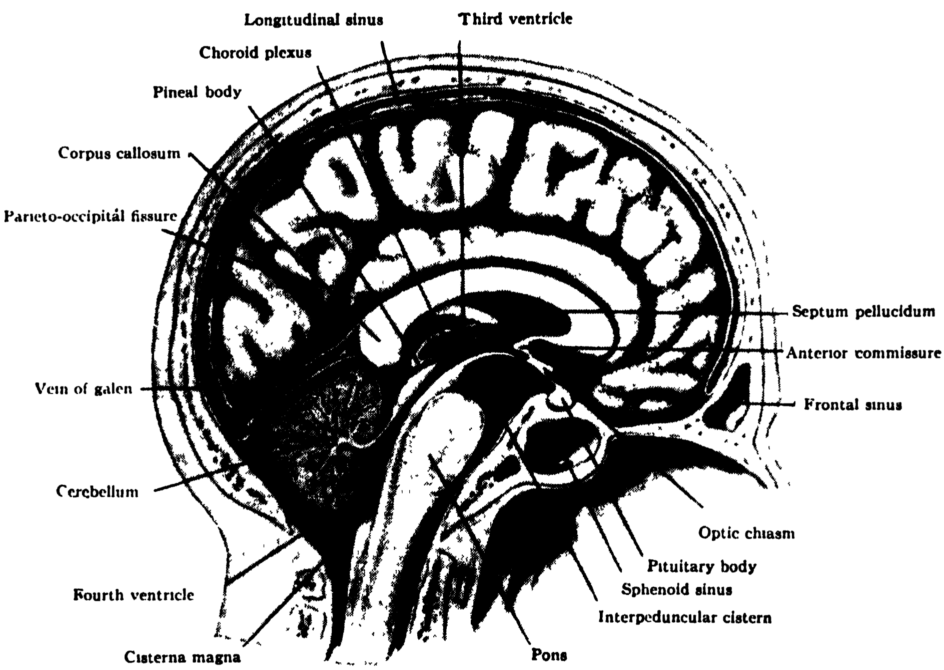
The **vertebrate** brain develops as a series of three expansions of the embryonic neural tube. Beginning at the anterior end these are known as the fore brain, mid brain, and hind brain, or as the prosencephalon, mesencephalon, and rhombencephalon. Later, the first and last subdivide, producing a total of five vesicles called the telencephalon, diencephalon, mesencephalon, metencephalon, and myelencephalon. These give rise to various adult structures as follows: The telencephalon produces two expansions, the cerebral hemispheres, which reach their highest development in man; they are the centers of reasoning and dominate all other regions. The telencephalon also gives rise to the **olfactory** centers and certain parts for which no simple description can be given. The diencephalon is important as the source of the **thalamus,** the retina of the **eyes,** the optic nerves, and the pars nervosa of the **pituitary gland.** The mesencephalon contains the centers of visual and auditory reflexes. The metencephalon gives rise dorsally to the cerebellum, which is a center of complex muscular coordination. The myelencephalon becomes the medulla oblongata, composed chiefly of great fiber tracts running between the higher centers and the spinal cord. In short, the human brain is made up of five portions: the cerebrum, cerebellum, midbrain, pons varolii and medulla oblongata.

The average weight of the human brain varies between 44 and 49 ounces. Growth of the brain ceases about the 19th to 20th year. It loses weight as age advances.

The surface of the brain is irregular, being divided into fissures and ridges (convolutions). The brain as well as the spinal cord is covered by three layers of



Main functional localizations in the cerebral cortex. *(From Callander's Surgical Anatomy, W. B. Saunders Co.)*



Ventricular and subarachnoid spaces viewed in median sagittal section of the head. *(From Callander's Surgical Anatomy, W. B. Saunders Co.)*

membranes called from without inward, the dura mater, arachnoid, and pia mater. The cerebrospinal fluid surrounds the brain and spinal cord lying beneath the arachnoid layer. This fluid is produced in the cavities of the brain (**ventricles**) and serves as a protective and nutritive medium for the brain and spinal cord. (A.W.L., R.S.M.)

BRAKE. Bracken. *Pteris aquilina.* A common fern widely distributed in temperate regions. It has an extensive **rhizome** creeping deep in the ground and bearing solitary leaves at intervals along its length. These erect leaves, called fronds, have a petiole (see **Leaf**) from 1–4′ long and a much dissected blade. The margin of this blade grows over and protects the spores born on the under side of the frond. Where it is at all abundant, as on abandoned rocky hillsides, the leaves may be gathered and used as bedding for livestock or even used as a coarse fodder in case of need. (R.M.W.)

BRAKE HORSEPOWER. The mechanical output of an engine, turbine, or motor is called the brake horsepower because one of the most common methods of testing for mechanical output is with the **Prony brake.** However, the output available at the shaft is called brake horsepower whether measured by brake or not. For example, when an **engine** drives an electric gener-

ator by direct connection, the horsepower available at the coupling between the machines is termed brake horsepower, but would not, under these circumstances, be measured by a brake. In the case of direct connected electric generating sets, the brake horsepower of the prime mover is found by dividing the electrical output from the generator, converted to horsepower, by the efficiency of the generator. The result is the generator input, which is the same as the mechanical output of the prime mover.

To measure brake horsepower by a Prony brake, readings of the weight registered on the scales and the speed of rotation of the brake drum are taken. In addition, the measured distance from the center of rotation to the force on the scales must be known. These quantities are substituted in the following formula to obtain brake horsepower:

$$\text{Brake horsepower} = \frac{2\pi WRN}{33{,}000}$$

W = net load on the scales, in pounds.
R = radial distance in feet to the line of action of the force registered on the scales
N = rotative speed, in revolutions per minute.

The W of the above formula is less than the load actually recorded on the scales because the tare weight must be deducted from the scale reading to give net effective weight. The tare weight is an allowance for the fact that the arm of the Prony brake itself gives some reading on the scale due to its unbalanced position, relative to the center of rotation. The tare weight is that weight which, acting at the scales, will give the same moment about the center of rotation that the unbalanced dead weight of the brake would produce. (F.T.M.)

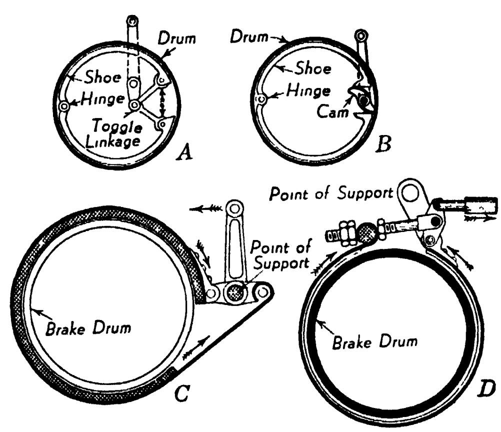
BRAKED LANDING. Landing, Types of.

BRAKES. A brake absorbs mechanical energy by transferring it into heat through frictional resistance The most frequently seen brake at present is a mechanical type used to reduce the speed of a machine or to bring it to a state of rest. Complete control of automotive vehicles necessitates brakes adequate to bring the vehicle from maximum speed to rest in a reasonable distance Stationary machines such as hoists or elevators have mechanical brakes, and numerous other applications will be found outside the automotive field.

The parts of a brake are the rotating part, which is generally, though not always, the drum, and a stationary part, the brake shoe. The shoe is pressed against the drum, generating a friction force at the contact surface. The brake shoe is frequently surfaced with a special material called brake lining, whose function is to provide for a high coefficient of friction, together with smooth braking action. The wear is largely taken by the lining. When not in use, the contact surfaces are separated by a light spring. Braking action may be applied by a mechanical linkage, such as lever or toggle joints, forcing the shoe against the drum, or by cables and pulleys, or by hydraulic means, incorporating a cylinder and plunger.

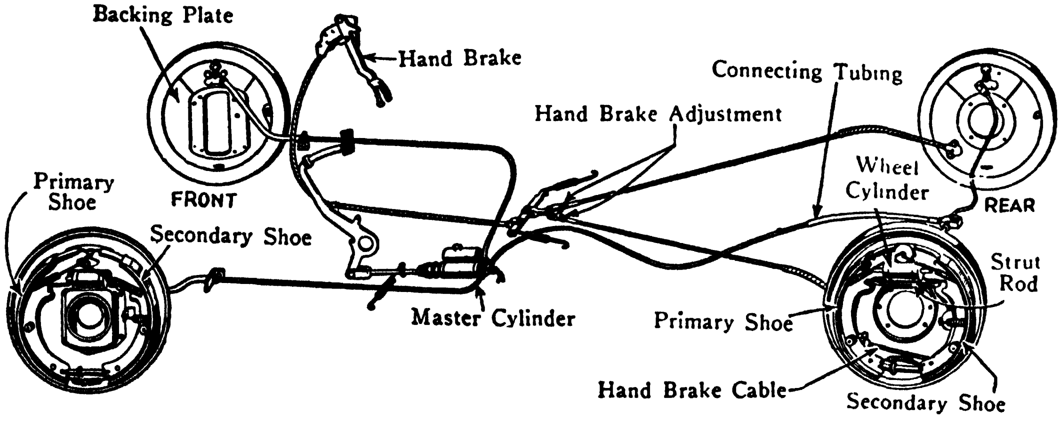
To bring a freely moving vehicle having velocity of V ft. per sec., and a weight of W lbs., to rest, requires the absorption of $\frac{1}{2}\frac{W}{g}V^2$ ft-lbs. of work at the brake drum. This energy must be equaled by the product of the friction force acting at the braking surface multiplied by the speed of rubbing, multiplied by the time during which the brake is in action, i.e., the time taken to stop. According to the theory of friction, as long as the pressure between brake shoe and drum remains constant, the friction force generated is independent of the rubbing speed.

There are many possible arrangements of brake shoe and drum. Some of these are shown in the accompanying figure, which shows internally expanding and exter-



Types of brakes found mostly on machines.

nally contracting brakes, as well as methods of applying pressure between the friction surface. To lower a load at constant speed, the brake shoes can be mounted on the rotating shaft of the hoist drum, free to move outward under the centrifugal force set up by rotation The brake drum is stationary Any tendency of the load to increase the speed of rotation is counteracted by an increased centrifugal force pressing the brake shoes more firmly against the drum. (See also **Sheet Metal Processes, Press-working, Air Brakes.**) (F.T.M.)



Passenger-car braking system comprising four-wheel hydraulic service brakes and rear-wheel mechanical parking brakes.

BRAMBLING. Aves, Passeriformes. A **finch** of the Old World which nests in northern Europe and Asia. *Fringilla montefringilla.* (A.W.L.)

BRANCHIAL. Pertaining to **gills.** (A.W.L.)

BRANCHIAL ARTERIES. Blood vessels which lead both to and from the **gills** in the fishes. Those which lead into the gills are the afferent branchials and those which lead out are the efferent branchials. (A.W.L.)

BRANCHIAL HEARTS. Muscular expansions of the branchial veins in the **squids** and related species which pump the blood through the **gills.** (A.W.L.)

BRANCHIAL VEINS. Branches of one of the large veins, the vena cava, of **cephalopod** mollusks which carry the blood to the gills on its way back to the heart from the anterior part of the body. (A.W.L.)

BRANCHIOPODA. A subclass of **crustaceans.** Not to be confused with Brachiopoda, the name of a phylum. (A.W.L.)

BRANCHIOSTEGITE. A lateral fold of the body wall which covers the **gills** in some of the **crustaceans.** (A.W.L.)

BRASS AND BRONZE. In addition to its important applications as a pure metal, copper is the base for a large number of alloys known as brasses and bronzes. The "brasses" include the alloys in which copper and zinc are the principal elements, although there are certain exceptions in which such alloys are called bronzes. The term "bronze" cannot be as definitely defined; it applies to the copper-tin alloys, and to many other copper-base alloys as indicated in the accompanying table.

The copper-base alloys have lower melting points than steels and are more readily produced from their constituent metals. They are comparable to steel in density, most copper alloys being only about 10% heavier, while those with considerable aluminum or silicon content may be slightly less dense than steel. Their strength properties, like those of steel, can be greatly varied by alloying and special processing, but in general they are at a lower strength level. The cost of copper-base alloys is generally higher than that of steels but lower than the nickel-base alloys.

Copper and its alloys have an infinite variety of uses reflecting their versatile physical, mechanical, and chemical properties. Some well-known examples are the high electrical conductivity of pure copper, the excellent deep-drawing qualities of cartridge case brass, the anti-friction properties of certain bearing bronzes, the resonant qualities of bell bronze, and the resistance to corrosion by sea water of several condenser-tube alloys. Representative compositions and typical applications of alloys generally produced in wrought forms such as sheets and plates, bars, shapes, wire, and tubing are listed.

The casting alloys, which are even more numerous than the wrought alloys, are used for bearings and other wearing surfaces, steam and water valves and fittings, electrical fittings, hardware, ornamental castings, and many applications requiring special corrosion-resisting qualities, pressure tightness, and good machinability.

REPRESENTATIVE BRASSES AND BRONZES

Name	Cu	Zn	Pb	Sn	Si	Ni	Al	Fe	Mn	Typical Applications—Wrought Forms
Gilding metal	95	5								Small arms ammunition
Commercial Bronze	90	10								Jewelry, screw products, fly screens
Red Brass (Rich Low Brass) *	85	15								Auto radiators, plumbing.
Low Brass	80	20								Wire cloth for paper making, flexible hose
Malleable Brass (Spring Brass)	75	25								Springs for moderate loading
Cartridge Brass	70	30	0.07 max							Cartridge cases, other drawn or spun products
Common High Brass	66	34	0.30 max							Cheaper drawing grade than cartridge brass
Muntz Metal *	60	40								Hardware, tubing
Free Cutting Brass	61.5	35.5	3							Screw machine products, hardware
Brass Forging Rod	60	38	2							Hardware, ammunition parts, plumbing
Admiralty Metal	70	29		1						Marine condenser and heat exchanger tubes
Naval Brass	60	39.25	0.20 max	0.75						Marine shafting, tube plates.
Manganese Bronze	58.5	39.0	0.20 max	1				1.1	0.1	Marine shafting, bolts, tie rods.
Aluminum Brass	76	22					2			High velocity condenser tubes.
Silicon Brass *	77	22			1					Refrigerator evaporators.
Copper-Nickel Alloy	70					30				Marine condenser tubes
Nickel-Silver (German Silver)	72	10				18				Silver-plated flatware, jewelry.
Nickel-Silver (German Silver)	65	17				18				Silver-plated flatware, jewelry.
Nickel-Silver (German Silver)	66	24				10				Silver-plated flatware, jewelry.
Phosphor Bronze	95			5						Springs and clips, friction plates in clutches.
Phosphor Bronze *	90			10						Springs and clips, friction plates in clutches
Aluminum Bronze	92						8			Bushings and bearings, machine parts
Aluminum Bronze *	89						10	75	25	Valve seats, bushings (heat-treatable grade)
Silicon Bronze	96				3				1	Tanks and chemical equipment
Beryllium Bronze	98	2% Be								Springs and diaphrams (high strength by heat treatment).
										Typical Applications—Castings
Leaded Yellow Brass	66	30	3	1						Radiator parts, fittings, general purpose alloy.
Brazing Solder	51	49								Pellets or lumps for brazing
Manganese Bronze	62	26.5					5	3	3.5	Marine propellers, shafts, gears.
Phosphor Bronze	76			24						Bells
Tin Bronze	88	2		10						Pressure castings for steam valves, pumps, gears.
Tin Bronze	89	3.5	1.5	6						Same as above—better machinability.
Leaded Red Brass	85	5	5	5						Free machining brass for valves, fittings, bushings.
Leaded Bronze	80		10	10						Bushings and bearings for heavy duty.
Leaded Bronze	70		25	5						Bushings and bearings for heavy duty.
Leaded Bronze	70		29						1% Ag	Steel backed, automotive & airplane engine bearings
Aluminum Bronze	86						10.5	3.5		High strength, corrosion resistant castings. Valve seats, worm wheels
Nickel-Silver (German Silver)	57	20	9	2		12				Plumbing fixtures, marine fittings.
Nickel-Silver (German Silver)	64	8	4	4		20				Plumbing fixtures, marine fittings.

* Also used as casting alloys.

(R.H.H.)

BRASSICA. Cruciferae. A genus of plants, largely wild in Europe and adjacent Asia, which give us many of our garden vegetables. All have characteristic and often noticeable odors due to various sulfur compounds which they contain. Many of them become obnoxious weeds when introduced into new countries. Among the species cultivated are the following:

Brassica oleracea is a native of the coast of Europe from England to the Mediterranean. The wild plant is a stout branching biennial bearing large white or pale yellow flowers, and having no tendency to "head." From this have arisen, perhaps as mutants, cabbage and Brussels sprouts, in which the leaves form tight heads, kohlrabi with its swollen stem, the cauliflower and broccoli with their compact, swollen inflorescences. Another form is red cabbage, used mainly for pickling. Sauerkraut is finely cut cabbage fermented in a salt juice made from its own sap; the sour taste is caused by **lactic acid** resulting from fermentation.

Brassica rapa is the turnip, a yellow-flowered biennial, growing wild in Europe and western Asia. It is a plant adapted to cool climates and much used as human food. Ruta-bagas are a related species.

Brassica napus, or rape, is a biennial 2–3′ high. It is used as a green manure plant, being plowed under to improve the soil, and as a forage plant. From its seeds rape oil is obtained and rape cake.

Brassica nigra, or black mustard, an annual of Europe and Asia, is used as a garnish and as a salad plant. The ground seeds, mixed with water, give us table mustard. *Brassica alba* is very similar to black mustard.

Brassica chinensis and related species are Chinese Cabbages, annual plants used in salads. (R.M.W.)

BRAYTON CYCLE. Gas Turbine Plant.

BRAZIL-NUT. *Bertholetia excelsa.* Lecythidaceae. In the forests of northern Brazil grows the giant tree, the **seeds** of which are the familiar Brazil-nuts These seeds are borne in a hard capsule 6–8″ in diameter and containing about two dozen seeds. The fruits develop high up in the air and fall to the ground without opening. This favors the gathering of the fruits, which are then split open and the seeds within removed. Immense quantities of the seeds are eaten yearly in Brazil and the United States. From the seeds an oil is obtained which is used in salad dressings, in paints and as a fine lubricant. (R.M.W.)

BRAZING. Brazing, according to the American Welding Society, is a group of welding processes wherein the filler metal is a non-ferrous metal or alloy whose melting point is higher than 1000° F, but lower than that of the metals or alloys to be joined.

At one extreme, brazing is very similar to **soldering** and is sometimes called hard soldering. A typical example of this is silver soldering or silver brazing using alloys containing 10–80% silver, balance principally copper and zinc. The melting points of these alloys are in the range 1175–1500° F., which is considerably higher than for soft solders. Silver solders are used to join both ferrous and the higher melting point nonferrous alloys. A composition containing 15% silver, 5% phosphorus, 80% copper is often used to join copper and brass.

Joints to be silver-soldered are usually designed so as to require only a thin film of filler metal which is drawn into the joint by capillary action when the solder becomes molten. This principle is also used in copper brazing, a high-temperature process in which pure copper is used to join close-fitting steel parts. Whereas most other forms of brazing depend on local heating with a torch or by other means, copper brazing is generally done in a furnace in which the part is heated to about 2050° F. A reducing atmosphere is used to prevent oxidation, thus no flux is needed as in nearly all other types of brazing. The copper is applied in any convenient form such as wire or sheet and is so placed that it can flow into the joint when molten. A mechanically tight joint such as a forced fit between two cylindrical parts is the most effective in drawing the copper into the joint. The resulting thin film of bonding metal gives a high-strength connection.

Where somewhat higher temperatures can be tolerated than those used in silver soldering, brazing spelter can be used. This is an alloy containing about equal proportions of copper and zinc and melting at about 1600° F. Like silver solders it flows readily between contacting surfaces when properly fluxed to prevent oxidation. The parts to be joined may be heated to the melting point of the spelter as in soft soldering, or may be dipped in a bath of molten brazing alloy.

Another type of brazing is similar to welding in many respects and is sometimes called bronze welding. The joints are generally of the V or fillet types in which a bead of filler metal is deposited with a torch. The technique differs from welding in that the base metal is not melted but only raised to the "tinning" temperature at which bonding takes place between the base metal and the brass or bronze filler metal by slight interdiffusion or alloying. The filler metals most widely used are brasses of the 60% copper-40% zinc type with additions of tin, iron, manganese, or silicon. For some purposes special bronzes are used such as aluminum bronze, silicon bronze, and nickel silver. The melting points of all of these alloys are higher than those of the silver solders but lower than that of pure copper. They are applied with a torch as in gas welding. Bronze welding is particularly well adapted to the repair of worn or broken parts. (R.H.H.)

BREADFRUIT. *Artocarpus incisa.* Moraceae. The breadfruit tree is a native of the East Indian and Pacific Islands, but has been widely planted in tropical regions everywhere. It is an attractive shade tree with large leaves deeply cut into pinnate lobes. The large ovoid fruits have a rough surface. Each fruit is composed of many **achenes** each surrounded by a fleshy **perianth** and growing on a fleshy receptable. These fruits are very rich in starch. Before being eaten they are roasted or boiled. Some of the improved varieties bear seedless fruits. (R.M.W.)

BREAKDOWN VOLTAGE. This is the voltage necessary to cause the passage of appreciable electric current without a connecting conductor. It is commonly used to express the voltage at which an insulator or insulating material fails to withstand the voltage and ceases to behave as an insulator. (L.R.Q.)

BREAM. Pisces, Teleostei. Several species of freshwater fishes (**Pisces**) of the Northern Hemisphere, allied to the carps. Two of the European species are known as the zope and the zarthe and one of the North American species is called the golden shiner. (A.W.L.)

BREAST. 1. The front of the **chest**. 2. The **mammary gland.** (A.W.L.)

BRECCIA. Breccia, derived from the Latin meaning broken, is a rock formed of angular fragments in a **matrix** which may be of similar or of different material.

Fault breccias result from the grinding action of the two **fault** blocks as they slide past each other. Subsequent **cementation** of these broken fragments may occur by means of mineral matter introduced by the ground water. **Talus** slopes may become buried and the talus cemented in a similar manner.

Volcanic breccias result from the cementation of fragments that have been broken by volcanic action. Sometimes the surface of a lava flow will harden while the interior will be yet liquid; the fracturing of this surface

material and its subsequent cementation by the uncooled lava produces a flow breccia.

The intrusion of **plutonic rocks** will often shatter the invaded country rock, forming a shatter breccia. In the case of plutonic rocks partly cooled and subsequently broken by further invasions of the magma, we have intrusive breccias. (E.S.C.S.)

BREED. A type of animal produced within the species by artificial selection, distinguished by definite hereditary characteristics but usually capable of interbreeding freely with other members of the species and so maintained only through artificial control of its propagation. Thus Guernsey and Angus cattle are breeds which would soon cease to exist in a state of nature, while the Michigan beaver and the Pacific beaver are self-maintaining in nature and are called subspecies. (A.W.L.)

BREEZE. Any light or moderate wind. Special names like sea breeze, lake breeze, land breeze, valley breeze, mountain breeze are used to describe particular breezes, usually of convective origin. (P.E.K.)

BREWSTER'S LAW. In 1815 Sir David Brewster discovered that for any dielectric reflector there is a simple relationship between the polarizing angle (see **Polarized Light**) for the reflected light of a particular wavelength and the **refractive index** of the substance for the same wavelength. The relationship is that the tangent of the polarizing angle is equal to the refractive index. For example, if the refractive index of flint glass for sodium light is 1.66 the polarizing angle for the reflection of sodium light by this glass is 50° 56′.

An interesting consequence of this relationship may be deduced. If the angle of incidence is the polarizing angle p, and the corresponding angle of refraction at a boundary with refractive index, n, is ρ, then, by Brewster's Law we have

$$\tan p = \frac{\sin p}{\cos p} = n = \frac{\sin p}{\sin \rho}.$$

Hence $\cos p = \sin \rho$ or $p + \rho = 90°$. It follows that when the light is incident at the polarizing angle, the reflected and refracted rays are perpendicular to each other. The law might be used as a means for measuring the refractive index of highly absorbing **dielectrics** such as polished obsidian, pitch, etc. (L.D.W.)

BRIAR. Heath Family.

BRICK. Brick ordinarily refers to a rectangular prism of clay or shale which has been burned in a kiln. Clay is no longer the only material for brick manufacture, being supplemented by slag, cement, lime, etc. However, when other than the ordinary structural clay brick is meant, a descriptive term such as fire-brick, sand-lime brick, etc., is employed. The principal classifications of brick are for structural purposes in buildings, for paving, and for lining furnaces, the latter known as refractory brick, or fire-brick. Ordinary bricks are made from a selected clay soil first by preparation of the clay by grinding and thoroughly mixing with enough water to make the mud. The bricks are then formed in the required shapes by one of several methods. In the soft mud method the prepared clay is quite plastic and the bricks are molded to shape by hand or machine. This is the principal method for making bricks by hand. The commercial manufacture of bricks is more frequently by the stiff mud process, in which the mud is less plastic, and is extruded through a die by pressure and wire cut to the proper size. Brick made from clay that is hardly more than dampened must be formed in molds by application of a great deal of pressure. As hydraulic presses are frequently used, these dry-pressed bricks are sometimes referred to as hydraulic-pressed brick. This process gives to the bricks a dense surface which makes them suitable for facing work.

After the bricks have been molded they are air dried and piled in the kiln for burning. It is quite difficult in any other than the continuously fired kilns, in which the bricks move slowly through the kilns on conveyors, to obtain uniform characteristics in all the brick, and so the product of the ordinary brick plant consists of various grades, ranging from hard brick to softer bricks, such as salmon brick. Hard-burned brick should be used for face work exposed to the weather, and soft brick for filling, for foundations, and the like. The standard brick measures approximately 2¼″ x 4″ x 8″, and has a crushing strength of between 1000 and 3000 lbs. per sq. in., depending on the quality. A highly impervious and ornamental surface may be laid on brick either by salt glazing, in which salt is added during the burning process, or by the use of a "slip," which is a glaze material into which the bricks are dipped. Subsequent reheating in the kiln fuses the slip into a glazed surface integral with the brick base.

A **refractory** brick is built primarily to withstand temperature. Good resistance to heat flow is not to be secured simultaneously with refractoriness. Indeed, the most refractory bricks usually have the highest thermal conductivities. It is important for the refractory brick to have high resistance to erosion by ash-laden gases and to the fluxing action of molten slag. It should not spall badly under rapid temperature changes, and its structural strength should hold up well under rapid temperature changes. Fire clay bricks are made from certain clays, including a plastic clay which binds the others into brick form. The firing in the kiln is carried out at a temperature such that the brick is partly vitrified. For special purposes they may be glazed by one of the methods previously described. The fire clay brick contains 30–40% alumina (see **Aluminum**), and about 50% silica (see **Silicon**). Progress in the art of combustion of fuels in furnaces has advanced the service requirements of refractory brick, sometimes to the point where they are so severe that a refractory superior to fire clay is needed. High alumina bricks containing 50–80% alumina, and correspondingly less silica, and silicon carbide, a product of the electric furnace, are typical of these super-refractories. Of course fire clay bricks are preferred wherever they give satisfactory service because they are lowest in cost of all the refractory bricks. The standard size of fire brick is 9″ x 4½″ x 2½″. (See **Ceramics.**) (F.T.M.)

BRICK ARCH. Arch.

BRICKWORK. When laid, **bricks** are bedded into a mortar which, hardening, bonds the separate bricks into a brickwork unit. A solid brick wall of more than one layer thickness has the different layers of brick bonded into each other by the use of headers, that is, brick laid perpendicular to the face of the wall. There are different systems of bonding, each of which gives a somewhat different appearance to the wall. In the common **bond** every fourth or fifth course is composed entirely of headers. In the English bond, every other course is a header course, while in the Flemish bond headers and stretchers alternate in each course. (See **Masonry.**)

The strength and durability of brickwork depend on the quality of mortar and excellence of workmanship with which the brickwork is laid. The proportions of the mortar are from one to three parts of dry sand to one part of Portland **cement**, depending on the strength needed. The cement mortar is much stronger than lime mortar, but the addition of a small amount of lime (see **Calcium**) to cement mortar renders it more readily worked without materially impairing its strength. In estimating brickwork, one rule is to allow 1000 standard brick and ½ cu. yd. of mortar for each 2 cu. yds. of brickwork in place. Some masons estimate

number of bricks by assigning 7 to each superficial sq. ft. of area of wall 1 brick thick. Brickwork varies in weight from 1.5 to 1.9 tons per cu. yd., depending on the density of the bricks used. The maximum crushing strength to which brickwork should be subjected is 170 lbs. per sq. in. when set in cement mortar, although this may be increased to 250 lbs. if the effects of eccentric loading and lateral forces are fully analyzed. (F.T.M.)

BRIDGE, STRUCTURAL. In civil engineering, a bridge is a structural unit or a series of structural units called spans designed primarily for the purpose of supporting moving loads, in addition to its own weight. The term bridge is generally associated with a structure which provides a means for foot, highway, or railroad traffic to pass over water, ground depressions or congested districts, although certain kinds of traveling cranes used for loading or unloading bulky materials such as ore or coal are sometimes referred to as bridges. All bridges are either stationary or movable. The so-called stationary bridges may be subdivided into spans of the arch type and those in which one end is allowed to move longitudinally so as to eliminate the horizontal force at the supports and also the stresses that would otherwise be induced by temperature changes. Movable spans are used in connection with low level bridges over navigable waters where these bridges interfere with shipping.

There are three general types of movable spans: namely, the bascule, the vertical lift, and swing bridge. The bascule bridge pivots about a horizontal axis or rolls back on circular segments. If the entire span rotates about a horizontal axis near one end, it is called a single leaf bascule. A double leaf bascule is one which is made up of two cantilevers, each of which rotates about a horizontal axis, forming a single span when closed. When the entire movable section may be lifted vertically, parallel to its original position, the bridge is called a vertical lift span. Swing bridges are those which turn in a horizontal plane about a vertical axis located at the center of the bridge. Movable bridges, when closed, are similar and perform the same service as the stationary types. Bridges may also be classified as framed **truss**, beam, or suspension bridges, depending upon the way in which they support the loads. All bridges are either straight or skew. When the end supports are not on lines at right angles to the longitudinal center line of the span, the resulting structure is called a skew bridge.

Bridges are usually constructed of **steel** or reinforced **concrete** although wood is sometimes used for temporary spans. Stone or **brick** are occasionally used for very short spans of the arch type. Reinforced concrete is particularly well adapted for use in connection with the beam or arched bridge since it can be molded into any desired form. The span length is limited, as in any bridge, by the strength of the component parts.

The ordinary framed bridge as illustrated in Fig. 1 is composed of two vertical trusses, a floor system, upon which the roadway or railway is directly supported, a

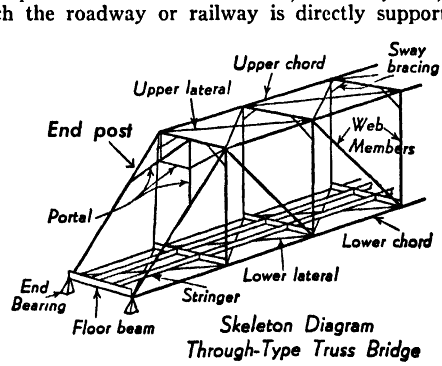


Fig. 1.

certain amount of bracing and the end **bearings.** The floor system consists of longitudinal beams called stringers which transfer the effects of the moving loads to transverse beams known as floor beams. The floor beams are connected to the trusses at the lower intersection points of the truss members. Each intersection point is called a joint or panel point. The truss is composed of an upper and lower chord and web members which are joined together in the form of triangles. Fig 2 shows some typical trusses. Since the loads are

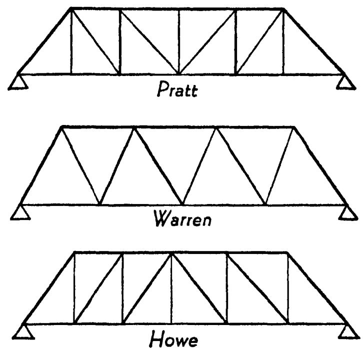

Fig. 2. Typical Framed Bridge Trusses.

applied to the truss at the panel points, the primary **stresses** will be axial. In this particular illustration the top chord will be in **compression** and the lower chord in **tension.** Some of the web members will be in tension, others in compression, but there are certain web members near the center of the span which may have either tension or compression depending upon the position of the moving loads. The bracing is usually made up of an upper and lower **lateral** system, sway frames, and portal bracing. These bracing systems resist the horizontal loads caused by wind, and, together with the floor system, tie the truss together forming a relatively rigid unit. Short-span framed bridges which do not require trusses sufficiently deep to allow for top chord, sway or portal bracing, because of interference with vehicular traffic are called pony truss spans. The trusses are the principal load-carrying components of the bridge, since they must support their own weight and the weight of the floor system in addition to the moving loads and wind loads. The total load on each truss is transferred through a horizontal **pin** to the end bearings or shoes, generally castings, which distribute the load to the supporting masonry. At one end of the bridge the bearings will be firmly fastened to the masonry, but at the other end they will be of the expansion type, which allows a limited amount of longitudinal movement to take care of the temperature changes in the structure. The separate structural members of a truss bridge are composed of rolled steel shapes or built-up sections formed by riveting two or more rolled shapes together. The truss members are connected at their intersections by **gusset plates** or pins.

Beam bridges are composed of two or more beams laid parallel to the direction of traffic. The roadway or track may be supported directly on the beams or by a stringer and transverse floor beam system connected to beams called **girders.** The construction of a simple deck **plate girder** bridge, frequently used for short railway spans, is shown in Fig. 3. Each girder is composed of a steel plate called the web to which are riveted four angles. Additional plates called covers are riveted to the angles. The two top or bottom angles and the attached cover plate form the flanges. The girders are stiffened laterally by the lateral system and the cross frames. A through bridge is a span of the beam or framed truss type in which the floor system is placed between the girders or trusses usually near the plane of the bottom flange or chords. In deck spans the floor

system is placed between the girders or trusses near the plane of the top flanges or chords, or rests upon them.

The simplest type of suspension bridge, applicable for short spans, consists of a floor system connected by

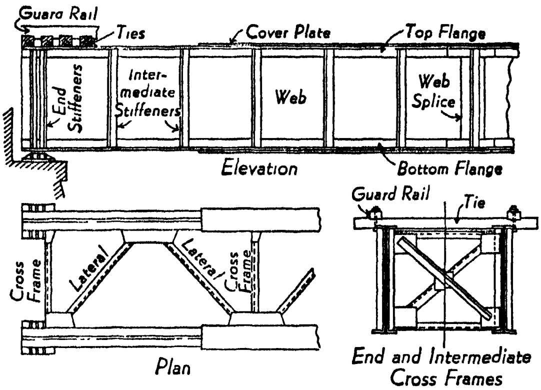

Fig. 3 Deck type girder bridge. *(Reprinted by permission from Modern Framed Structures,* Part III, *by Johnson, Bryan and Turneaure, published by John Wiley & Sons, Inc.)*

hangers to two cables or chains. The latter pass over towers and are firmly anchored at the end of the span. For longer spans it becomes necessary to connect the floor system to stiffening trusses which distribute the moving loads more uniformly to the hangers. This method of distribution reduces the distortion of the cable or chain. The hangers are formed of twisted wire ropes while the cable may consist of twisted wire ropes or a number of parallel wires securely bound together into a compact unit of circular cross-section. The chain is made up of a number of separate tension links called **eye-bars.** The floor system, stiffening truss and towers are constructed of rolled steel shapes.

In its simplest form the cantilever bridge consists of a suspended span and two anchor spans. Each anchor span which rests on two **piers** is made up of an anchor arm and a cantilever arm. The latter projects beyond the river pier to form a support for one end of the suspended span. Cantilever bridges may be either **trusses** or **plate girders.** The former are particularly well adapted to long-span construction.

A continuous bridge is one which rests on three or more supports and is capable of transmitting both **shear** and **moment** throughout its length. These bridges which are statically indeterminate may be plate girders or trusses. The continuous bridge is more rigid than the cantilever bridge but settlement of the supports has a marked effect on the stress distribution.

A bridge of two or more spans which is supported at each intermediate pier by a hinged quadrilateral is called a Wichert truss. This type of bridge is determinate (see **Determinate Structure**) and therefore the stresses are not affected by settlement of the supports.

A pontoon bridge is a floating roadway which is used to bridge narrow bodies of water. It consists of barges called pontoons which carry a roadway made up of beams which, in turn, support a plank floor. The pontoons must be firmly anchored so that they will not float out of position. The pontoon bridge is generally used for military purposes although there are instances in which this type of bridge has been constructed for ordinary vehicular and pedestrian traffic.

The type of bridge to be used at a particular location depends upon many considerations. Typical arched bridges are shown in Fig. 4. Satisfactory **foundations,** possible **pier** locations, and access to the bridge are some of the local conditions which will influence the selection of a particular type. From an architectural standpoint the type which is used should harmonize with the natural surroundings. When the cost of a bridge

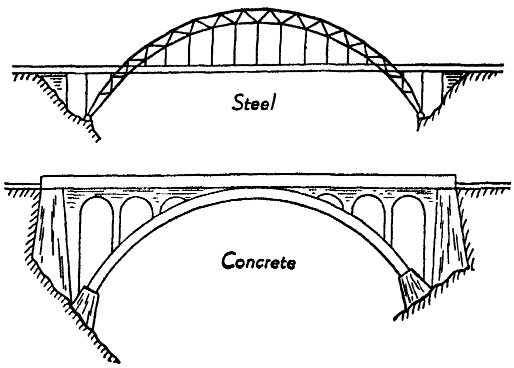

Fig. 4. Typical arched bridges.

project is limited to a predetermined amount certain types of bridges are automatically eliminated. (L.D.W., F.T.M., C.W.C.)

BRIDGING TRANSFORMER. Telephony.

BRIGHTNESS. The brightness of a surface giving out light, as viewed from a given direction, is the quantity of light flux emitted in that direction per unit area of cross-section perpendicular to that direction. This term may be applied either to a self-luminous body, as a white-hot metal plate, or to an illuminated diffuse reflector. If the emission is 1 lumen per sq. cm. of normal cross-section, the brightness is said to be one lambert; while 1 lumen per sq ft., likewise, is called a foot lambert. (See **Photometry.**)

For a good diffuser (like a hot, sooty plate), the brightness is the same in all directions. Thus a white-hot cylindrical rod photographs as a uniformly white streak, as if it were a flat strip. The well-known **cosine emission law** may be deduced from this fact. (L.D.W.)

BRIGHT'S DISEASE. Nephritis.

BRILL. Pisces, Teleostei. A flat-fish, *Psetta laevis,* found in British waters and valued as food. The more familiar members of this group are the **flounders, turbot,** and **soles.** (A.W.L.)

BRINE-FLY. Insecta, Diptera. **Flies** whose larvae live in strong briny or alkaline waters. They belong to the family Ephydridae which also contains species whose larvae live in fresh water and one remarkable insect which lives in pools of crude petroleum in the California oil fields.

Large quantities of the **larvae** of certain species are washed ashore along some of the western alkaline lakes and are gathered by the Indians as food under the native name koo-tsabe. (A.W.L.)

BRINELL HARDNESS. Hardness.

BRITISH THERMAL UNIT. B.T.U.; Calorimetry.

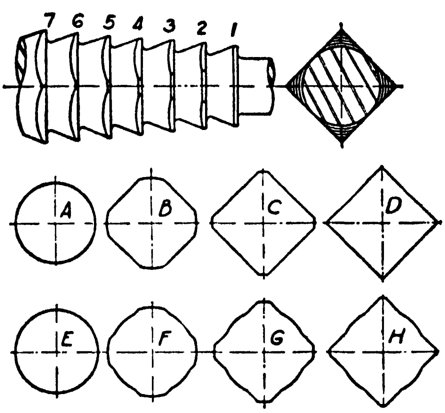
BRITTLE-STAR. Echinodermata. **Ophiuroidea.**

BROACHING. Broaching is a machining process whereby one or more cutters with a series of teeth are pushed or drawn entirely across a surface consisting of straight-line elements, and is analogous to single-stroke filing. Broaching is done on manually-operated presses, on pull-screw machines, or on hydraulically-actuated broaching machines or presses. The broach has teeth which increase in height towards one end, and is held in the screw socket of the broaching machine screw or ram by a taper cotter. The first few teeth on the broach are low to permit the small end of the tool to be passed

through the cylindrical hole in the work; the intermediate teeth remove most of the metal; and the last few teeth finish the surface to size. Each tooth removes an equal amount of metal. The broach is drawn or pulled through the work by a non-rotating screw which receives its axial motion from a rotating nut driven by a pulley.

Push broaching is usually performed on vertical machines with broaches that are comparatively short to insure stiffness. They are ordinarily employed where only a small amount of metal is to be removed. A set of several short push broaches may be required to remove the same amount of metal that one long pull broach will handle. Short broaches are used whenever possible, however, as they are easy to make, harden, and handle.

Broaches are extensively employed for machining square and hexagonal holes and splined shaft fittings. The figure illustrates a square hole broach which transforms the round hole shown at *A* to the square hole



Square hole broach.

shown at *D*. Tooth number 1 fits the round hole *A*; *B* shows the cutting effect of tooth 3, and *C* the cutting effect of tooth 5, while *D* shows the finishing effect of tooth 7. (In actual practice, of course, more than seven teeth are required for an operation of this character; the intermediate teeth between 1 and 2, 2 and 3, etc., have been omitted for sake of clarity) An alternate design and process are shown at *E, F, G,* and *H*. The hole at *E* is drilled slightly larger than the side of the square and the final teeth of the broach do not remove all the material in the corners. The design at *H* is practically as effective for power transmission as the design shown at *D,* and may be more easily broached. (H.C.H.)

BROADBILL. Aves, Passeriformes. Oriental birds (**Aves**) with a shallow but very broad beak. (A.W.L.)

BROADTAIL. Aves, Psittaciformes. A group of **parrots** or parraquets found only in Australia, Norfolk Island, and Tasmania. (A.W.L.)

BROCCOLI. Brassica.

BROCHANTITE. A mineral composed of basic **copper** sulfate corresponding to the formula $CuSO_4 \cdot 3Cu(OH)_2$, crystallizing in the **orthorhombic** system in needle-like prisms, or forming **druses** or masses. Hardness, 3.5–4; specific gravity, 3.9; vitreous luster; color, green; streak, green; transparent to translucent.

Brochantite is a secondary mineral occurring in the oxidized zones with other copper minerals, and is found in the Urals, in Rumania, in Sardinia; Cornwall, England; Chile. In the United States this mineral has been found at Bisbee, Arizona, Utah, in the Tintic District and in Inyo County, California. Brochantite was named for Brochant de Villiers. (E.S.C.S.)

BROCKET. Mammalia, Artiodactyla. *Cariacus.* Small South American **deer** of several species. Unlike most deer they are solitary in habits. (A.W.L.)

BROMIC ACID AND BROMATES. Bromic acid ($HBrO_3$) is a colorless liquid, miscible with water. A solution of bromic acid is decomposed upon boiling, but can be concentrated in vacuum up to 51% $HBrO_3$, with considerable decomposition. A strong oxidizing agent, e.g., **sulfides, sulfur, sulfites** to **sulfuric acid, thiosulfates** to tetrathionates (but depending upon the conditions), **oxalates** to **carbon dioxide.**

Prepared by reaction (1) of barium bromate solution and sulfuric acid, and filtering off barium sulfate.

Potassium bromate is formed (1) by **electrolysis** of **potassium** bromide solution, with stirring, heated, and over some hours, (2) by reaction of bromine and potassium chlorate solution, (3) by heating potassium **hypobromite** solution.

Metallic bromates are solids, soluble in water, except that **silver, lead, barium, thallous** bromates are slightly soluble. Basic bromates require the presence of a little free acid for solution. Bromates when heated, evolve oxygen and leave the bromide (or oxide) as residue.

Upon addition of hydrobromic acid (or bromide plus dilute sulfuric acid) bromate liberates bromic acid, which reacts with hydrobromic acid to form bromine. (R.K.S.)

BROMIDE. Bromine.

BROMINE. Symbol: Br. Atomic number: 35. Atomic weight: 79.916. Density: 3.12. Melting point: −7.2° C. Boiling point: 58.8° C. (**Isotopes**: page 290.)

Bromine is a brown liquid, volatilizing at room temperature to a red vapor, which has a very irritating effect on eyes and throat. Liquid bromine causes painful sores upon contact with the flesh. Somewhat soluble in water, soluble in carbon tetrachloride to reddish-brown solution. Discovered by Balard in 1825. Used chiefly in photography, and in the preparation of organic chemicals, among which is ethylene dibromide, which is used in conjunction with lead tetraethyl in gasoline. Many bromides are used in medicine, especially those of potassium, sodium, ammonium, lithium, strontium and calcium. They are used chiefly as sedatives to lessen nervous excitability and irritability, to inhibit vomiting, to prevent or lessen the extent, discomfort or frequency of convulsive or spasmodic states, especially **epilepsy.** The drug is given orally or rectally. When given over too long a period, especially in sensitive subjects, a stubborn skin eruption may develop. Other toxic reactions include nervous system depression, coma, and sometimes psychotic manifestations. The severity of the bromide poisoning may be measured by determining the blood bromide level.

Bromine occurs as bromide in sea water (0.188% Br), in the mother liquor from salt wells of Michigan, Ohio, West Virginia, and in the potassium deposits of Germany and France. Separated from solutions by treatment with **chlorine**, and purified by distillation.

Bromine is soluble in water, 3.6 grams per 100 grams of water at 20° C., in ether, ethyl alcohol, carbon disulfide, chloroform, carbon tetrachloride, and potassium bromide solution. Bromine reacts (1) with **sodium** thiosulfate solution to form sulfate, (2) with **sulfurous acid** to form sulfuric acid, (3) with **hydrosulfuric acid to form sulfur,** (4) with unsaturated **hydrocarbons** to form organic bromo-compounds, e.g., ethylene bromide, acetylene tetrabromide, (5) with benzenoid **hydrocarbons** to form organic bromo-compounds, e.g., bromobenzene, dibromobenzene.

Acids: Hydrobromic acid (HBr); hypobromous acid (HBrO); bromic acid ($HBrO_3$). (See each acid.)

Bromate: (See **Bromic Acid.**)

Bromides: **Sodium** bromide (NaBr), **potassium** bromide (KBr), **ammonium** bromide (NH_4Br) are soluble

bromides; **silver** bromide (AgBr), **mercurous** bromide (HgBr), **mercuric** bromide ($HgBr_2$), **lead** bromide ($PbBr_2$) are insoluble bromides. (See **Hydrobromic Acid.**) Organic bromo-compounds, see Bromine, Organic Compounds, below.

Chloride: Bromine chloride (BrCl).

Fluoride: Brominetrifluoride (BrF_3).

Iodide: Bromine iodide (BrI).

Hydride: Hydrogen bromide (HBr), colorless gas when pure (frequently contains free bromine as reddish gas), melting point —86° C., boiling point —67° C., very soluble in water yielding hydrobromic acid. Formed by reaction of (1) red **phosphorus,** bromine and water under the proper conditions, (2) bromine and **hydrogen** gases.

Hypobromite: (See **Hypobromous Acid.**)

Sulfide: (See **Sulfur,** Bromide.)

Organic bromo-compounds:

Paraffin and benzenoid **hydrocarbons,** e.g., ethane and benzene, respectively, react with bromine by *substitution* of bromine for hydrogen (hydrogen bromide also formed), e.g., ethane to yield ethyl bromide (C_2H_5Br) plus further substitution products; benzene, in the presence of a **catalyzer,** e.g., iodine, phosphorus, iron, to yield bromobenzene (C_6H_5Br) plus further substitution products; toluene, under like conditions to benzene, to yield ortho-bromotoluene and para-bromotoluene ($CH_3C_6H_4Br$) plus further substitution products, but at the boiling temperature, in sunlight, dry, and in the absence of a catalyzer, to yield paraffin-side-chain substitution products, benzyl bromide ($C_6H_5CH_2Br$), benzal bromide ($C_6H_5CHBr_2$), and benzotribromide ($C_6H_5CBr_3$).

Olefin, acetylene, and benzenoid **hydrocarbons,** e.g., ethylene, acetylene and benzene, respectively, react (1) with bromine by *addition,* e.g., ethylene dibromide ($C_2H_4Br_2$(1,2)), acetylene tetrabromide ($C_2H_2Br_4$1,1,2,2,), benzene hexabromide ($C_6H_6Br_6$), also carbon monoxide yields carbonyl bromide ($COBr_2$), (2) with hypobromous acid by *addition,* e.g., olefins form, for example, ethylene bromohydrin ($CH_2Br{\cdot}CH_2OH$), (3) with hydrogen bromide by *addition,* to form, for example, ethyl bromide ($CH_3{\cdot}CH_2Cl$) from ethylene. When the two olefin carbons have an unequal number of hydrogens attached, bromine of hydrogen bromide and hydroxyl of hypobromous acid attach to the carbon having the smaller number of hydrogens.

Oxygen-function compounds, e.g., **ethyl alcohol, acetaldehyde, acetone, acetic acid,** react (1) with bromine, to form *bromo-substituted* corresponding or related *compounds,* e.g., ethyl alcohol or acetaldehyde to yield bromal ($CBr_3{\cdot}CHO$), acetone to yield bromoacetone ($CH_2Br{\cdot}CO{\cdot}CH_3$) acetic acid to yield, at the boiling temperature, dry, and in the absence of a catalyzer, monobromoacetic acid ($CH_2Br{\cdot}COOH$), dibromoacetic acid ($CHBr_2{\cdot}COOH$), tribromoacetic acid ($CBr_3{\cdot}COOH$), the substitution taking place on the alpha-carbon (the carbon next to the carboxyl-group (—COOH)), (2) with **phosphorus** bromides, to form corresponding *bromides,* e.g., ethyl bromide (C_2H_5Br), ethylidene dibromide (CH_3CHBr_2), acetone bromide ($(CH_3)_2CBr_2$), acetyl bromide (CH_3COBr), (3) with hydrobromic acid, concentrated, alcohol forms the corresponding bromide.

Bromoform is made by reaction of acetone or ethyl alcohol with sodium hypobromite; carbon tetrabromide by reaction of carbon disulfide (CS_2) plus bromine (Br_2) in the presence of iron, heated; sulfur monobromide (S_2Br_2), boiling point 56° C. at 0.2 mm. also formed.

Use is made of the diazo-reaction (see **Azo- and Related Compounds**) to introduce bromine into benzenoid compounds.

Many of the bromo-compounds are used as reagents or as intermediate compounds in organic chemistry. When paraffin bromo-compounds are treated (1) with **sodium** hydroxide dissolved in alcohol, hydrogen bromide is removed, e.g., ethyl bromide ($CH_3{\cdot}CH_2Br$) yields ethylene ($CH_2{:}CH_2$), ethyl dibromide ($CH_2Br{\cdot}CH_2Br$) yields acetylene (CH CH); (2) with magnesium or zinc and alcohol, bromine is removed, e.g., ethylene dibromide ($CH_2Br{\cdot}CH_2Br$) yields ethylene ($CH_2{:}CH_2$), acetylene tetrabromide ($CHBr_2{\cdot}CHBr_2$) yields acetylene ($CH{\vdots}CH$).

(R.S.M., D.M.H., R.K.S.)

BROMLITE. Alstonite. The mineral Bromlite or Alstonite is a rare **barium-calcium carbonate** that may contain small amounts of **strontium** carbonate as well. It occurs at Bromly Hill, near Alston, Cumberland, England (whence the two names) in association with **calcite** and **witherite.** (E.S.C.S.)

BROMOIL PROCESS. A process of photographic printing based upon the selective adherence of an oil pigment to an image in tanned gelatin. It was once widely used by pictorialists because of the control over tone values which it affords but is now nearly obsolete. A print on bromide paper is bleached in a solution, the chief ingredients of which are usually potassium ferricyanide—or copper sulfate—and potassium bichromate. In this solution the silver image is bleached and the gelatin in contact with the silver image tanned, the degree of tanning being more or less proportional to the amount of silver present. After fixing and washing to remove the silver image, the water adhering to the surface of the print is blotted off and a thick ink of the type used by lithographers is applied locally with a brush. The ink is accepted by the tanned gelatin but repelled by the water contained in the unhardened gelatin. Thus an image in pigment is built up on the differentially hardened gelatin. By repeated application of the ink to certain portions and by changing its consistency the bromoil worker is able to change the tone values of the original photographic image to meet his own artistic ends.

A development of the bromoil process known as bromoil transfer consists in transferring the pigment from the finished bromoil to a plain drawing paper by passing the two together in contact through a transfer press. Bromoil transfer results in an image of pigment on plain paper thus eliminating all traces of the photographic base. (C.B.N.)

BRONCHIECTASIS. A chronic progressive disease of the bronchi or bronchioles due to weakening or destruction of the muscle layer of their walls. The condition may be caused by repeated bronchial infections, or by the plugging of a bronchus by mucus or a foreign body, with stasis and chronic infection. **Whooping cough** may be followed by bronchiectasis. Destruction of the muscle results in the formation of cylindrical saccular or fusiform dilatations of the bronchi, with stagnation of secretions in them and consequent infection. The disease is characterized by chronic cough productive of large amounts of foul-smelling sputum. Except for **tuberculosis,** it is the most common cause of **hemoptysis.** The course is a chronic one with acute flare-ups of fever and constitutional symptoms. Surgical removal of the affected area of the lung offers the only cure. **Sulfonamide** therapy and **penicillin,** with postural drainage, are effective in controlling the element of infection. (D.M.H.)

BRONCHITIS. An inflammation of the bronchial tubes usually associated with a similar process in the trachea (tracheobronchitis) (see **Respiratory System**). The disease may be primary but most often is associated with an upper respiratory infection, a "cold." It may also be part of the disease picture of **tuberculosis, whooping cough, measles, influenza, typhoid fever,** and **asthma. Pneumonia** is the chief and most dangerous complication; bronchopneumonia is often ushered in as an acute bronchitis.

The etiology of bronchitis in the course of an upper respiratory infection is obscure. Although many pathogenic organisms may be found in the bronchial secretions there is no evidence that they play a significant role in the genesis of the condition. The possibility that the disease is caused by a filterable **virus**—similar to the agent which causes the common cold—has been considered, but not proven.

In acute bronchitis the most prominent symptom is cough, dry at first, but later productive of sputum. Low-grade fever may be present for several days. Soreness of the chest and a sensation of tightness beneath the sternum are common. The general lassitude and discomfort subside with the fever, but the cough may persist for several weeks. Treatment of the acute disease consists of steam inhalations and drugs to control involuntary coughing and to liquefy the sputum.

Chronic bronchitis usually effects old people, men more than women. It follows repeated attacks of acute bronchitis, and often is associated with **bronchiectasis,** pulmonary **emphysema,** and **asthma.** The only symptom is persistent cough, usually worse in the winter months. The general health is not impaired. The treatment is directed toward the underlying cause if the bronchitis is secondary; drugs which keep the sputum liquid and help control the cough may be useful. (D.M.H.)

BRONCO or **BRONCHO.** Mammalia, Perissodactyla. **Horses** of western North America, descended from stock originally brought in by the Spanish conquerors. They are noted for endurance and spirit. There is no certain distinction between the terms broncho and mustang, and both are embraced by the name Indian pony. (A.W.L.)

BRONZE. Brass and Bronze.

BRONZE AGE. Paleontology of Man.

BRONZITE. Enstatite.

BROOD SAC. A pouch in which the eggs are retained during development in some of the **crustaceans.** (A.W.L.)

BROOKITE. Brookite, composed of **titanium** dioxide, TiO_2, is an **orthorhombic** mineral of the same chemical composition as **rutile** and **octahedrite.** It was named for the English mineralogist H. J. Brooke. (E.S.C.S.)

BROOM CORN. *Andropogon Sorghum* var. Gramineae. A variety of a tropical grass, **sorghum,** characterized by having an inflorescence in which the branches are very long and slender, growing in loose **panicles.** The plant is extremely drought resistant and so adapted for regions having an arid climate. The close-bunched stiff inflorescent-branches account for the principal use of broom corn, i.e., the manufacture of brooms and whisk-brooms. Large quantities are grown in Oklahoma. (R.M.W.)

BROWN AND SHARPE. Gauge Number; Taper.

BROWN BODY. In the **bryozoa** the entire active portion of the individual, known as the polypide, degenerates in certain conditions to form a compact mass known as the brown body. The enclosing sheath or zooecium forms a new polypide whose stomach sometimes encloses the brown body representing the previous individual. In such cases the mass is later discharged by way of the anus. (A.W.L.)

BROWN PRINT. Drawing Reproduction.

BROWN ROT. Ascomycetes and Bacteria.

BROWNIAN MOVEMENT. The random movement observed among microscopic particles suspended in a fluid medium. The phenomenon was observed in 1827 with suspensions in liquids, **colloids,** by Robert Brown, English botanist, who is said to have attributed it to living organisms. Not until the kinetic theory was developed was it generally understood to be due to the thermal agitation of the suspending medium. A smoke particle floating in the air, for example, is battered on all sides by the high-speed air molecules. The resultant displacement is for the most part nearly zero, but there are statistical inequalities which now and then reach such magnitude as to produce motions visible in a high-powered microscope, and which result in an irregular migration of the particle. In fact, such particles may be regarded essentially as huge molecules, with mean square speeds of thermal motion proportionately smaller as their masses are larger than that of the true molecules of the surrounding medium. A mathematical analysis of the problem by Einstein in 1905 led to an equation connecting the observed motions with the **Boltzmann constant,** the development being based upon the law of **equipartition of energy;** and the agreement between the predictions of this theory and experimental results is very satisfactory. (L.D.W.)

BROWN-TAIL MOTH. Insecta, Lepidoptera. A European species, *Euproctis chrysorrhea,* related to the tussock moths of this continent. It was introduced into Massachusetts during the last century and together with the **gypsy moth,** another introduced species, has become an important pest in the New England states and the adjacent Canadian provinces, attacking shade and fruit trees. Spraying with **lead** arsenate in the late summer has been found an effective method of control, as well as the collection and destruction of the winter nests in which the caterpillars hibernate.

The hairs of the **larva** are very irritating to the human skin. (A.W.L.)

BRUCELLOSIS. Undulant Fever.

BRUCINE. Alkaloids.

BRUCITE. The mineral brucite is **magnesium** hydroxide corresponding to the formula $Mg(OH)_2$; **iron** and **manganese** may occasionally be present. The crystals are usually tabular **rhombohedrons** of the **hexagonal** system; it may also occur fibrous or **foliated.** Brucite has one perfect cleavage parallel to the prism base; hardness, 2.5; specific gravity, 2.38–2.4; luster, pearly to vitreous; commonly white but may be gray, bluish or greenish; transparent to translucent. Brucite is a secondary mineral found with **serpentine** and **metamorphic** dolomites. It has been found in Italy, Sweden, and the Shetland Islands; and in the United States in New York, Pennsylvania, Nevada and California. Brucite was named in honor of Archibald Bruce, an American physician. (E.S.C.S.)

BRUNTON COMPASS. Specially designed for geologists and fitted with a clinometer and other devices for reading both horizontal and vertical angles. (R.M.F.)

BRUSH. A brush is a device for conducting current to or from a rotating part. The brush is stationary, and is held and guided by a fixed brush holder in which it slides freely. There may be several brushes side by side to form a single-brush set. The rotating member may be the **commutator** of a d-c **generator** or **motor,** or it may be the slip **rings** of an a-c motor or generator. Examples of brushes might also include those used in **magnetos** and static electricity machines.

Brush material is usually carbon, though spring-leaf copper and copper gauze are used in special cases. Circuit connections to carbon brushes are made directly to the brush by means of short flexible cables from the external circuit because the contact surface between brush holder and brush is an unreliable conductor.

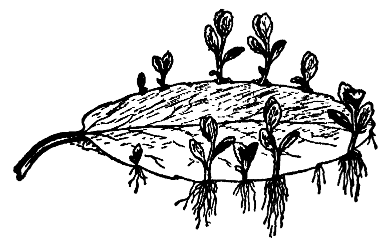
Brushes wear and must be replaced periodically. Also, their ends should fit commutators so as to make good contact over the entire brush surface. They may sometimes need periodic redressing with sandpaper in order to maintain the proper arc for contact. The most serious fault of a brush is the formation of electric **arcs** between the rotating member and the brush. This may be due to condition of the brush, vibration of the brush in the holder, or improper setting of the brush. The position of the brushes on the commutator is adjusted so the coils or turns being shorted by the brushes will have a minimum voltage. This means that the coil sides will be in the position of minimum flux, which position will depend upon the load unless correction is applied. In modern machines interpole windings are used to compensate for the distortion of the field caused by the armature current so the brush position is opposite the center of the poles. In machines without some form of compensation the position will be to one side of this and is adjusted to give minimum sparking under normal load. (F.T.M., L.R.Q.)

BRUSH DISCHARGE. Ionized Gases.

BRUSH TURKEY. Aves, Galliformes. Large dull-colored birds (**Aves**) of several species found in New Guinea and Australia. They deposit their eggs in large heaps of decaying vegetation. (A.W.L.)

BRUSSELS SPROUTS. Brassica.

BRYOPHYLLUM CALYCINUM AND OTHER SPECIES. Crassulaceae. A genus of tropical plants which are frequently seen in cultivation because of their habit of reproducing by means of their leaves. If a mature leaf is removed from one of the plants and placed on damp sand, within a short time there appear in the notches of the leaf margin tiny roots and later small green plants which soon become independent of the parent leaf. Infrequently the little plants appear in the notches while the leaf is still attached to the parent plant. The explanation of this uncommon habit is that in the development of the leaf certain cells in the leaf notches remain permanently **embryonic.** For some reason their

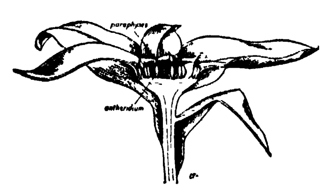


Vegetative reproduction of *Bryophyllum calycinum.* New plants develop in the notches of the leaves.

development is inhibited so long as the leaf remains attached. Severing the leaf removes the inhibition and the embryonic cells resume active development. (R.M.W.)

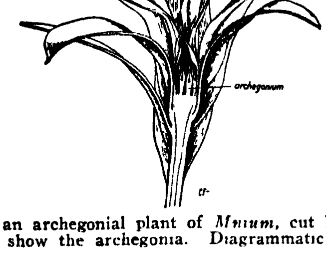
BRYOPHYTES. The second subdivision in the Plant Kingdom, comprising Mosses and Liverworts (or Hepatics), is a small group of plants, having some 20,000 species. Most of these are terrestrial plants. The bryophytes inhabit a wide range of habitats, from dry barren rocks to submerged objects, but are most frequent where an abundance of moisture is assured. They are found on trunks and branches of trees, on the soil, and even on the leaves of some tropical plants.

The body of these plants is small and without much structural complexity. Rhizoids, slender outgrowths which serve mainly to attach the plant to its substratum and which serve only slightly as absorbing organs, are common. They may be single celled or multicellular, but are colorless. The habit of the plant body is diverse. In many hepatics it is a thin flat



The tip of a plant of *Mnium* which bears antherida, cut lengthwise to show the antheridia. Diagrammatic.

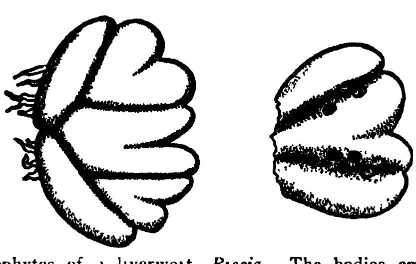
thallus, one to several cells thick Often the edge of the thallus is so lobed that it appears to be differentiated into a central stem and lateral leaves. In the mosses this differentiation is much greater. There is an erect central stem which bears many thin radiating leaves. However complex the structure may be, the cells of the plant-body of a bryophyte show very little differentiation. The central cells may be longer; other cells may have thicker walls; cells nearer the surface contain more **chloroplasts,** but there is never any real modification of cells to form **vascular elements.** The latter are entirely wanting in this group, which are therefore sometimes called Atracheata, that is, plants without any vascular cells, to distinguish them from the ferns and



The tip of an archegonial plant of *Mnium,* cut lengthwise to show the archegonia. Diagrammatic

seed plants, the Tracheata, characterized by a highly developed tissue.

The sex organs of the bryophytes are highly developed objects, which distinguish this group very sharply from the lower plants, both **algae** and **fungi.** The **antheridium,** in which the sperm cells are formed, is a club-shaped multicellular body. The **archegonium** is a flask-shaped body, also multicellular. Antheridia and archegonia may be formed on the same plant or on different plants; often they appear at different times so that self-fertilization is largely prevented. The sperm, a biciliate actively motile cell, swims to the egg which is located in the swollen basal portion of the archegonium. There a sperm unites with the egg to fertilize the latter and incite growth of a new generation. But the plant resulting from this fertilized egg is one entirely unlike the parent plant. Commonly it is a well-developed plant, but less conspicuous than the one on which it is usually entirely dependent for its food supply. When mature it forms a large mass of small spherical cells called spores, which are freed from the body in which they are formed and carried away by currents of air. On reaching a suitable environment each spore germinates and eventually form a plant like that which bore the sexual organs. There is then in the bryophytes a very definite **alternation of generations,** a haploid sexual generation called the gametophyte, bearing male and female sex organs and a diploid asexual generation called the sporophyte, in which are formed haploid asexual spores. The gametophyte is green and carries on **photosynthesis.** In most



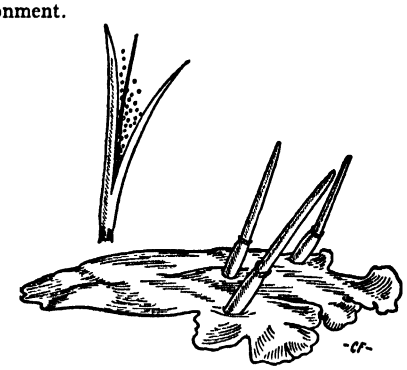
Gametophytes of a liverwort, *Riccia* The bodies embedded in the right-hand plant are sporophytes

cases it is terrestrial. The sporophyte, however, depends on the gametophyte for its food supply and water.

Bryophytes are separated into two classes, the Hepaticae or liverworts and the Musci or mosses. Each class is subdivided into three orders, as follows:

Class I. Hepaticae.
  Order 1. Marchantiales.
  " 2. Jungermanniales.
  " 3. Anthocerotales.
Class II. Musci.
  Order 1. Sphagnales.
  " 2. Andreaeales.
  " 3. Bryales.

The liverworts are generally considered lower in the scale of evolution than the mosses. The thallus, or plant body, of the liverworts, is prostrate and flat When it forks, the two branches are equal, a method of branching known as dichotomous. In the second order of liverworts the thallus is so divided as to appear leafy, the order often being called the leafy hepatics. All liverworts have unicellular **rhizoids** borne on the lower side of the thallus by which they are anchored firmly to the substratum. The sex organs are borne embedded in the body of the thallus or in special outgrowths called gametophores, which rise from the thallus. The small sporophytes are dependent on the gametophyte for their nutrients. In these plants an asexual reproduction occurs by means of small masses of cells which develop from the gametophyte to which they are attached by a very slender stalk. These small bodies, called gemmae, are easily separated from the parent plant. They develop into a new gametophyte when they are carried by wind or water to a suitable environment.

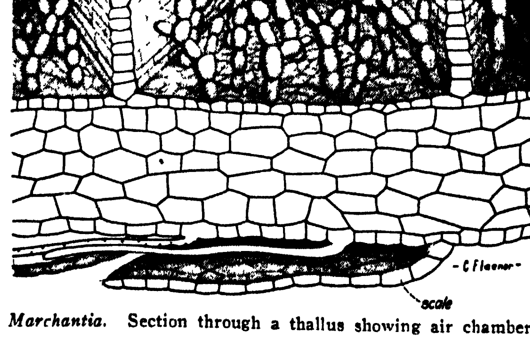


Anthoceros, one of the horned liverworts. The "horns" are sporophytes. A portion of a sporophyte is shown separately to illustrate the method of liberation of spores.

The three orders of the liverworts form an interesting series, of increasing complexity. The Marchantiales include forms which have a prostrate thallus, often showing a structure of considerable complexity. The sporophyte is very simple. Growth of the thallus is by repeated divisions of a single apical cell which itself sometimes forms two such cells, whose continued divisions form a dichotomous branching of the thallus. As the thallus increases in length at the apical end, death of the cells occurs at the other end, so that the plant slowly grows ahead until in time a fork is reached and the two halves separate by progressive disintegration of the older portions.

One of the simplest members of this group is *Riccia,* a small plant found either floating on still waters or growing on wet mud. Some species are thick and fleshy, others are slender much-branded bodies, having a very evident median groove.

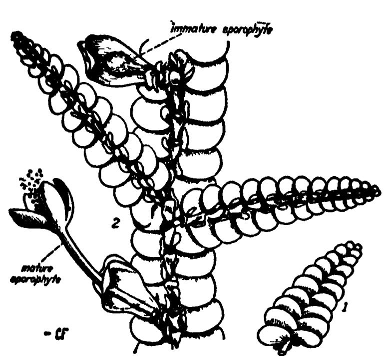
From the lower surface single-celled rhizoids grow downward. From this surface also, thin scales or plates are developed, forming an overlapping row along the middle of the thallus. Both antheridia and archegonia are formed on the upper surface along the midrib. The antheridia have a wall a single cell in thickness, and contain many sperm mother cells, each of which divides to form two biciliate sperms. The archegonial wall is also a single cell in thickness, and encloses a



Marchantia. Section through a thallus showing air chambers.

row of six cells, four of which are the canal cells, the other two a ventral cell and an egg cell. When the latter is mature, the other five disintegrate, while at the same time the apical cells of the archegonium split apart, forming a canal through which the sperm swims to fuse with the egg. The sporophyte which develops from the fertilized egg remains embedded in the gametophyte thallus; when mature it is nearly all sporogenous tissue enclosed in a thin-walled capsule. A more complex member of this order is *Marchantia.* In this the gametophyte thallus is several inches long and from a half an inch to an inch broad. Its lower surface bears rhizoids and scales, or lamellae, quite like those of *Riccia.* The upper part of the thallus, just beneath the upper surface, contains a number of large chambers, each connected with the outside air by a large pore. Gemmae are produced in cup-like organs growing out of the upper surface of the thallus. The sexual organs in this plant are not formed in the thallus, but are borne on special erect branches called gametophores. Antheridia and archegonia are borne on different plants, the plants thus being dioecious. They are quite like the antheridia and archegonia of *Riccia.* The sporophyte is considerably larger than that of *Riccia,* with a well-developed foot attaching it to the gametophyte, a short thick stalk which pushes the spore-containing capsule out from the tissues of the gametophore. Not only does this capsule contain large numbers of spores, but also, scattered among the spores, slender elongate cells called elaters, whose walls have spiral thickenings These are affected by differences in humidity which cause the elater to twist about, apparently to stir up and loosen the spores. In *Marchantia* the gametophyte is very elaborately developed; the sporophyte, very simple.

The second order of liverworts is divided into two suborders, the Anacrogynae, in which the archegonia are borne on the upper surface of the thallus, and the Acrogynae, in which they are borne at the apex. In the species of the Acrogynae the thallus is so incised



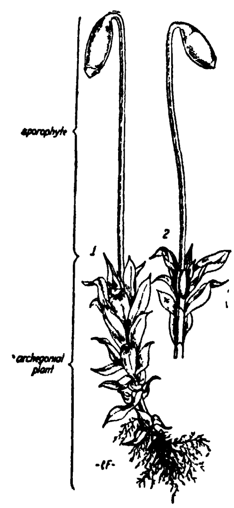
Porella, a leafy liverwort. 1, a branch seen from the upper side 2, a portion of a plant seen from the lower side, sporophytes also are visible attached to archegonial branches, each partially enclosed in a perianth.

on its margins that it appears to bear two rows of small leaves. The Jungermanniales are small plants, many of them very delicate, growing in wet places, either on the ground or on rocks and tree trunks. Cellular differentiation in the thallus is very slight. In them the sporophyte is much more highly developed than in the first order. It has a long slender erect stalk which bears the capsule. When the latter is mature, it splits into four valves, which spread apart and free the spores within. Members of this suborder also form a series more or less as do the Marchantiales. The third order, the Anthocerotales, is a small group containing three genera. In all of them the gametophyte thallus is of a very simple type, with no great cellular differentiation, and with the sex organs always embedded. In this order the sporophyte is a most interesting object, far advanced in comparison with those of the other liverworts. It is an erect, slender more or less cylindrical object composed of a basal foot and a long capsule. The central portion of the capsule is a rod of sterile tissue called the columella. Around it is the sporogenous tissue. The spores are formed in zones alternating with narrow bands of sterile tissue. Outside the sporogenous tissue is a wall of sterile tissue composed of chlorophyll (see **Pigments in Plants**) containing cells. The epidermal portion of this wall contains many stomata (see **Stoma**). The basal portion of the sporophyte, just above the foot, is composed of meristematic cells, which by their divisions cause the capsule to elongate. When mature this capsule splits into two valves which pull apart, resembling horns. These plants, with their very simple gametophyte and very elaborate sporophyte, contrast strikingly with the Marchantiales, with their elaborate gametophyte and simple sporophyte.

Mnium, a common genus of mosses.

The liverworts are of no economic importance, but are of interest because they suggest what may have been the habit of those plants which first left the water and grew on land. They have never become independent of water, since it must be present if fertilization is to occur.

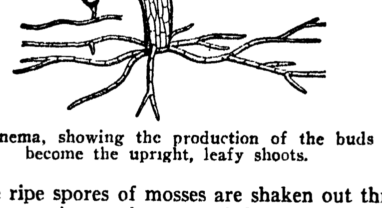
The number of mosses known is much larger than the number of liverworts Mosses are found in many different regions, being much more abundant than liverworts, and able to grow under a wide range of environments. They are found in greatest abundance in moist shaded regions where they often cover an extensive area. Other species grow on the trunks of trees, often well above the ground, where they are exposed for long periods of time to desiccation. In tropical forests mosses often clothe not only the trunks but also the branches of trees with a thick green covering; they may even succeed in growing on the thick evergreen leaves which characterize many tropical trees. Some species of mosses grow well on the exposed surfaces of barren rocks. A few are aquatic, living entirely submerged in running water throughout their existence.



The sporophyte of a moss *Mnium* 1, the sporophyte attached to the gametophyte. 2, the same, the gametophyte being cut away to show the enlarged venter of the archegonium in which the foot of the sporophyte is anchored.

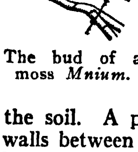
Usually moss plants are small (often tiny), and seldom exceed a few inches in length. A few genera, such

as *Fontinalis,* which grows in water, and several tropical members, grow to lengths of 10–15", which is very unusual in this group. Moss plants show a much higher development than hepatics. Usually the gametophyte, the part ordinarily seen and called a moss, has a very distinct, often erect stem, which bears many small radiating leaves. In each leaf there is generally a fairly evident midrib. There are many **rhizoids** growing from the lower part of the stem and attaching the plant to the ground. The rhizoids of mosses are longer than those of liverworts and are multicellular. There is no true vascular system in any moss, though the cells of the central portion of the stem are often much longer and more slender than those surrounding them. The sexual organs of mosses are very similar to those of hepatics and are borne at the tips of the stem or branches. Biciliate sperms are formed which must have water in which they can swim to the egg. The fertilized egg gives rise to a sporophyte which is much more highly organized than that of liverworts but still entirely dependent on the gametophyte. The basal portion of the sporophyte is the foot, a mass of cells in close contact with those of the gametophyte. Above the foot there is a stalk which in most mosses is very long and slender. It bears at its top a capsule or spore-bearing sac. This capsule has a very specialized structure. The axis of the capsule is a mass of sterile tissue called the columella. Around this the sporogenous tissue occurs, in turn surrounded by a wall many cells thick and with large cavities within it. The basal part of the capsule is also a mass of sterile tissue, often considerably swollen, known as the apophysis. The apical portion of the capsule is very complex. Over its surface is the operculum, a layer of cells, which completely covers it and which falls off like a lid when mature. Beneath this and distinct from it is the peristome, which, when mature, splits into a number of slender teeth which react to changes in humidity, rolling back when dry and closing together when wet. Surrounding the developing capsule and remaining around it for some time is a loose jacket of cells in no way connected with it. This is the calyptra, formed from cells of the gametophyte which were originally cells of the archegonal



Moss protonema, showing the production of the buds which become the upright, leafy shoots.

wall. The ripe spores of mosses are shaken out through the apical opening and scattered by currents of air. On germinating, these spores do not give rise to a new moss plant directly. Instead they form a slender branching filamentous structure called a protonema which very much resembles certain kinds of **algae.** There are two types of cells composing the protonema: one contains many **chloroplasts** and so carries on **photosynthesis:** the other lacks chloroplasts and forms colorless rhizoids which grow downward and attach the protonema to the soil. A peculiarity of the protonema is the cross-walls between cells: they are commonly diagonal to the long axis of the filament rather than at right angles. From the cells of the protonema short erect branches

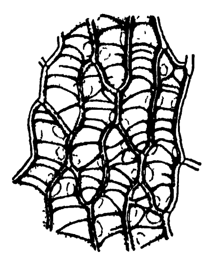


The bud of a moss *Mnium.*

ending in small buds are formed. These buds develop into erect moss plants. The life-history of a moss plant shows a very distinct **alternation of generations.** In addition there is the juvenile phase of the gametophyte, the protonema.

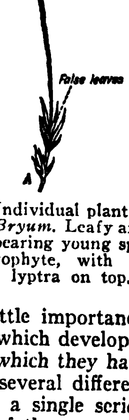
Sphagnum sporophyte attached to a leafy plant.

The first order of mosses, the peat- or bog-mosses, contains the single genus *Sphagnum* with many species of world-wide distribution, always growing in low, wet bogs. These mosses are considered very primitive. The gametophyte has an erect stem from which arise numerous branches, all of two kinds, either spreading, or pendent against the stem. The many leaves are small and but a **single cell in** thickness. Some of the cells are small and elongated, forming a fine anastamosing network in the leaf. These are living cells containing chloroplasts. The openings of the network are filled by very large inflated cells with thin walls and no protoplasm. Large pores in the walls of these dead cells permit free passage of water into the cell cavity. The small sporophyte has a spherical capsule, which is black or dark brown, and a very short stalk. The sporophyte is borne at the end of a specialized structure called a pseudopodium which lifts the sporophyte above the tuft of branches at the top of the gametophyte. The protonema of *Sphagnum* is a small flat thallus resembling that of the Anthocerotales.



A portion of a leaf of *Sphagnum,* the peat moss. Surface view.

Peat-mosses are the only members of the Bryophyte group which have any commercial value. Growing slowly for long periods of time, they gradually accumulate in the wet bogs in which they are found. Gradually the lower parts amass, together with such debris as may have accumulated, forming a compact mass known as peat, and used as fuel. The ability of the large hollow cells of the leaf of *Sphagnum* to absorb and retain large quantities of water leads to the extensive use of *Sphagnum* moss as a material in which to pack live plants for shipment. For this reason also, and because *Sphagnum* is naturally a sterile substance, harboring few bacteria, certain species have been used as surgical dressings, especially in times of great need.



Individual plant of *Bryum.* Leafy axis bearing young sporophyte, with calyptra on top.

The Andreaeales is a small group of small mosses growing on the surfaces of siliceous rocks. They are unimportant.

Most mosses belong to the third order, the Bryales, which are the true mosses.

As a group the Bryophytes are of little importance. They are recognized as primitive plants which developed from some simple ancestral forms from which they have gradually diverged independently along several different lines. The existing forms do not form a single series, representing stages in the development of the most advanced forms, nor are they plants from which the higher plants have taken their origin. In this group the gametophyte appears in its most advanced form. (See also **Paleobotany.**) (R.M.W.)

BRYOZOA. One of the smaller divisions of the animal kingdom, made up of **sessile** animals which are mostly colonial, forming branching or encrusting colonies or large jelly-like masses. The appearance of certain branching colonies is the source of the name Bryozoa, which means moss-animals. Both marine and fresh-water forms are known.

These animals are distinguished by the following characters: 1. The individual consists of two parts, a sheath-like zooecium or body wall and an enclosed polypide consisting of the alimentary tract, tentacle sheath and tentacles. 2. The body is coelomate but not segmented. 3. A circlet of **ciliated** tentacles occurs at the free end of the body; in most species they can be retracted when the animal is disturbed or at rest. 4. The alimentary tract is sharply bent, mouth and anus opening near each other at the free end.

The phylum is divided into two classes:

Class Endoprocta. Primitive bryozoans whose tentacles cannot be retracted but are folded inward and covered by a fold of the body wall. The anus opens inside the circlet of tentacles.

Class Ectoprocta. Tentacles retractile. Anus opening outside the circlet of tentacles. (A.W.L.)

B SUPPLY. Power Supply.

B.T.U. Also Btu. Abbreviation for **British Thermal Unit.** (See **Calorimetry.**)

BUBBLE CAP. Distillation.

BUBBLE OCTANT. Sextant.

BUBO. Swelling of a lymphatic gland, particularly in the groin. Buboes develop in response to infection and are usually tender and painful; they may break down and discharge **pus.** They are most commonly associated with **lymphogranuloma inguinale, chancroid** and **plague** (bubonic plague), although they occur in the course of other diseases such as **gonorrhea, syphilis, tularemia.** (D.M.H.)

BUCCAL CAVITY. The cavity of the mouth. (A.W.L.)

BUCCAL FUNNEL. The funnel-like depression leading to the mouth in the **lampreys.** (A W.L.)

BUCK. The male **deer** and sometimes the male **sheep.** Also applied to entire species in some cases, as the water-buck and prongbuck. (A.W.L.)

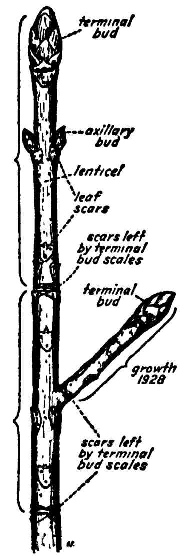
BUCKLING. Columns.

BUCKWHEAT. *Fagopyrum esculentum.* Polygonaceae. Outside of the grasses, buckwheat is the only plant used to any extent as a cereal in the United States. It is an erect branching plant from one to four feet tall, with a small root system and a smooth rather weak stem at each node of which is borne a single heart-shaped leaf. The **inflorescence** is a many-flowered **raceme,** the individual flowers being white or pink-tinged. The **calyx** lobes, five in number, are colored; there is no **corolla.** There are eight **stamens** and a single one-celled **ovary** which bears three curved **styles.** Cross-pollination is brought about by the numerous insect visitors attracted by the pleasant fragrance of the flowers. The mature fruit is a triangular brown or black **achene.** The single seed within contains an abundance of white **endosperm** high in starch content.

Buckwheat is an Asiatic plant which is cultivated in widely scattered regions. It grows well in cool climates, on poor soils, and where the growing season is short. The plant is often used as a green manure, being turned under to enrich the soil. Pancake flour is made from buckwheat seeds. The grain is also used as food for poultry and other domestic animals, either whole or divested of the hulls. Buckwheat flowers are an important honey source, producing a very finely flavored product. (R.M.W.)

BUD. In zoology, a bud may be defined briefly as an outgrowth from the body which develops into a new individual. In botany a bud is an undeveloped shoot and normally occurs in the axil of a leaf or at the tip of the stem. Once formed a bud may remain for some time in a dormant condition, or may develop into a shoot immediately. Various factors may cause dormant buds to grow, such as removal of the apical bud or of the part of the stem above the bud.

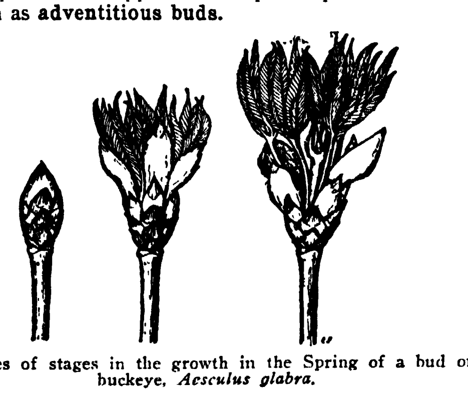
The buds of many woody plants, especially in temperate or cold climates, are protected by a covering of modified leaves called scales which tightly enclose the more delicate parts of the bud. Many bud scales are covered with a gummy substance, which serves as added protection. When the bud develops, the scales may enlarge somewhat but usually drop off, leaving on the surface of the growing stem a series of horizontally elongated scars. By means of these scars one can determine the age of any young branch, since each year's growth ends in the formation of a bud, the development of which causes the appearance of an additional group of bud scale scars. Continued growth of the branch causes these scars to be obliterated after a few years so that the total age of older branches cannot be determined by this means.



Twig of buckeye, *Aes culus glabra,* showing two years' growth.

In many plants scales are not formed over the bud, which is then called a naked bud. The minute undeveloped leaves in such buds are often excessively hairy. Such naked buds are found in shrubs like the **Sumach** and **Viburnums** and in herbaceous plants. In many of the latter, buds are even more reduced, often consisting of undifferentiated masses of cells in the axils of leaves. A head of cabbage (see **Brassica**) is an exceptionally large terminal bud, while Brussels sprouts are large lateral buds.

Since buds are formed in the axils of leaves, their distribution on the stem is the same as that of leaves. So we find alternate, opposite and whorled buds, as well as the terminal bud at the tip of the stem. Whorled buds are found in many coniferous trees, as the fir or spruce. In many plants buds appear in unexpected places: these are known as **adventitious buds.**



A series of stages in the growth in the Spring of a bud of buckeye, *Aesculus glabra.*

Often it is possible to find in a bud a remarkable series of gradations of bud scales. In the Buckeye, for example, one may observe a complete gradation from the small brown outer scale through larger scales which on unfolding become somewhat green to the inner scales of the bud, which are remarkably leaf-like. Such a series suggests that the scales of the bud are in truth leaves, modified to protect the more delicate parts of the plant during unfavorable periods. (A.W.L., R.M.W.)

BUDAN'S THEOREM. Budan's theorem is of help in locating the real **roots** of a **polynomial equation;** it is stated as follows:

Let $P(x) = 0$ be a polynomial equation of degree n with real coefficients. Let a and b be real numbers, neither of which is a root of $P(x) = 0$, and suppose $a < b$. Let V_a denote the number of variations of sign of

$$P(x),\ P'(x),\ P''(x),\ \cdots,\ P^{(n)}(x)$$

(successive **derivatives**) for $x = a$, after vanishing terms have been deleted, and similarly V_b the number of variations for $x = b$. Then $V_a - V_b$ is either the number of real roots of $P(x) = 0$ between a and b or exceeds the number of these roots by a positive even integer. A root of multiplicity m is here counted as m roots. (L.L.S.)

BUDDING. This term is used to designate a process of **asexual reproduction** in which the young are formed as outgrowths of the parent body. It is limited to animals or plants of relatively simple structure. In this process a portion of the wall of the parent **cell** softens and pushes out. The protuberance thus formed enlarges rapidly while at this time the nucleus of the parent cell divides One of the resulting nuclei passes into the bud. Presently the bud becomes cut off from its parent cell and the process is repeated. Often the daughter cell starts to bud before it becomes separated from the parent, so that whole colonies of adhering cells are formed. Eventually cross walls cut off the bud from the original cell.

1 2 3 4 5 6 7

1, 2, 3, 4, and 5 Reproduction by budding Yeast cells stained to show nucleus. (*Redrawn from Guillermond, The Yeasts, John Wiley & Sons, Inc.*) 6 and 7. Colony formation by rapidly growing yeast. Nuclei not stained

The term budding is also applied to a process of embryonic differentiation in which new structures are formed by outgrowth from preexisting parts.

A third use of the term budding is discussed in the article on **grafting and budding.** (A.W.L., R.M.W.)

BUDGERIGAR, BUDJERIGAR. Aves, Psittaciformes. An Australian **parraquet,** chiefly green with a blue tail and yellow face. Also known as the Australian love-bird in captivity. (A.W.L.)

BUERGER'S DISEASE. (Thrombo-Angiitis Obliterans.) An inflammatory disease of the peripheral blood vessels which is followed by obliteration of their lumina. This results in impairment of the circulation to the extremities, manifested by coldness, **cyanosis,** pain, and eventually **gangrene** of the affected part. The lower extremities are most often affected. The disease is commoner in males than in females by a ratio of 75 to 1, and over half the cases occur in Jews. The onset is usually between the ages of 20 and 45. Treatment is directed toward improving the circulation of the extremities by special exercises, elevation of the affected part, drugs, and occasionally surgical measures which remove vessel-constricting impulses by interfering with their nervous pathways. (D.M.H.)

BUFFALO. Mammalia, Artiodactyla. Hoofed animals of several species, some of which have been domesticated. They are strongly built, with a short heavy neck and a broad muzzle. The horns are hollow and are not twisted or branched.

The Cape buffalo, *Syncerus caffer,* is an African species with short curved horns whose bases are broadly expanded over the upper part of the head. It is found in swampy ground. In western Africa is another species, the short-horned buffalo or bush cow. The Indian buffalo, *Anoa bubalis,* is another water-loving species whose sweeping curved horns extend back toward the withers. This species is domesticated and in the Philippines is called the carabao. Another smaller species of the Philippines is known as the tamarao, *Anoa mindorensis.*

The term buffalo does not apply correctly to the American bison. (A W.L)

BUFFALO CARPET-MOTH. Insecta, Coleoptera. More properly known as the carpet **beetle** but misnamed through the similarity of habits of its **larva** and those of the clothes moths.

The true carpet beetle is an introduced European species, *Anthrenus scrophulariae,* whose larva eats woolen materials of all kinds as well as furs and feathers. The adult is a compact oval insect about one-eighth inch long and marked with brick-red, black and white, and the larva is a brown hairy grub. A number of other species, native to North America, have the same habits and may be equally troublesome. The adults frequent flowers and eat pollen, hence they may migrate readily to houses. They are important pests in museums.

In the home, good housekeeping methods are usually an adequate safeguard against these pests. In special cases fumigation is necessary to destroy them but as a rule the use of sprays now supplied commercially for application to clothing and other fabrics is the only unusual measure required. Fumigation with **carbon disulfide** is the method commonly used in museums to destroy them; the explosive nature of this fluid and its vile odor do not recommend it for home use. (A.W.L.)

BUFFALO FISH. Pisces, Teleostei. *Ictiobus.* North American food fishes (**Pisces**) of three species, related to the suckers. (A.W.L.)

BUFFALO GNAT. **Black Fly.**

BUFFER AMPLIFIER. This term is commonly applied to an amplifier stage whose main function is to isolate the **oscillator** of a **transmitter** from the main power amplifiers. The frequency of an oscillator depends, among other factors, upon the load which is applied to it. Since, for satisfactory communication, it is highly desirable that the oscillator frequency remain constant, buffer amplifiers are always used in broadcast transmitters and are usually used in others. Such an amplifier usually operates Class C (see **Amplifiers**) with the grid drive so low the **grid** does not draw current from the exciting circuit and hence doesn't load it. The output circuit of the buffer can then supply the normal grid load of a conventional Class C amplifier without this load affecting the oscillator. Sometimes more than one buffer stage is used to make certain that no load is reflected back to the oscillator. (L.R.Q.)

BUFFING. A finishing process for producing a lustrous surface, usually on sheet metal. Buffing is usually

effected by using a buffing wheel composed of layers of cloth sewed together to which a cake abrasive is periodically applied. (H.C.H.)

BUFFLEHEAD. Aves, Anseriformes. *Charitonetta albeola.* A small North American **duck** of wide distribution. (A.W.L.)

BUG. Insecta, Hemiptera. **Insects** with sucking mouth parts usually arising near the front of the head, with antennae usually long but few-jointed, and with wings, when present, thicker at the base and membranous at the tip, overlapping when folded to form a more or less conspicuous X on the back. The bugs are so diverse that no concise definition can be generally adequate. The term bug is not synonymous with insect. (A.W.L.)

BUHR-STONE. Relatively porous, calcareous, and siliceous **sandstones** with sharp or angular grains, used in making millstones. (R.M.F)

BULB. A thick short stem which grows many thick leaves in which food reserves are stored. In many bulbs the leaves are closely wrapped together, forming a compact body called a tunicated bulb, as is the case in the onion. In other bulbs the fleshy leaves are loosely arranged to form a scaly bulb, such as the Easter Lily. Bulbs are particularly common in **monocotyledonous** plants, and aid the plants greatly in surviving long dry seasons. So regions subject to regularly recurrent dry seasons are particularly rich in bulb-forming plants. Commonly the term bulb is erroneously applied to any fleshy underground plant part, regardless of its nature, so that **rhizomes, corms** and **tubers** are all popularly classed as bulbs. The dahlia "bulb," for instance, is really a fleshy root. (R M.W.)

BULBIL (OR BULBLETS). In a few plants there occur small reproductive bodies called bulbils. An example is found in the small black objects growing in the axils of the leaves of Tiger Lilies. These are really buds in which the scales are very much swollen; when mature the whole body falls to the ground and under favorable conditions puts out roots and in time grows into a new plant. Similar bodies are found in the familiar onion sets, and in several sedges Serving the same purpose are the small globose bodies which develop on the leaves of several species of ferns, as for example, *Cystopteris bulbifera* All such bodies form one method of vegetative propagation. (R.M.W.)

BULBUL. Aves, Passeriformes. Birds (**Aves**) of several species found in Africa and the Oriental region, related to the **babblers.** They are said to be melodious singers. (A W.L.)

BULBUS ARTERIOSUS. A muscular expansion of the ventral aorta at its origin from the **heart** in bony fish. Distinguished from the bulbus cordis or conus arteriosus by the lack of cardiac muscle. (A.W.L.)

BULBUS CORDIS. A term closely linked with conus arteriosus and rather loosely used. Where the ventral aorta of vertebrates joins the ventricle of the heart, especially in the 2-chambered stage in the fishes and in embryos of higher classes, a prominent, somewhat conical expansion of the tube is found. This expansion may contain valves and its wall may be composed in part of cardiac muscle. In the former case it appears to be an an expansion of the artery and is properly termed the conus arteriosus. In the latter it seems to be a specialized portion of the ventricle and is called the bulbus cordis. The two characteristics may be combined to constitute a bulbo-conus. This term is sometimes applied to the corresponding portion of the embryonic circulatory system, which is better designated as the **truncus arteriosus.** (A.W.L.)

BULK MODULUS. Elasticity.

BULKHEAD. A bulkhead is a partition or a transverse strengthening frame. Ships' bulkheads are the important transverse partitions which subdivide the hold into separate water-tight compartments, being built from the keel to the bulkhead deck They must be not only water-tight, but have sufficient structural strength to resist the bursting pressure to which they will be subjected when one bulkhead space is filled with water, while the adjacent one is empty.

In construction, any wall used to restrain fluid or semi-fluid pressure, such as that resulting from water or saturated earth in foundation excavations, is called a bulkhead or bulkhead wall. (F.T.M., E.W.S.)

BULL. The male of certain animals, as domestic cattle, the bull elephant, and the bull alligator. (A.W.L.)

BULLFINCH. Aves, Passeriformes. *Pyrrhula.* Birds (**Aves**) of northern Europe and Asia, related to the grosbeaks. (A.W.L.)

BULLFROG. Amphibia, Salientia. *Rana.* Large frogs, closely related to the more familiar grass frogs and leopard frogs. The bullfrogs reach a length of 8". The flesh of the bullfrog is delicious. (A W.L.)

BULLHEAD. Pisces, Teleostei. Small **catfishes** native to the streams and lakes of the eastern and central United States. Excellent food fishes. The common bullhead is also called the horned pout, *Ameiurus nebulosus.* (A.W.L.)

BUMBLEBEE. Insecta, Hymenoptera. Stoutly built hairy **bees** of moderate to large size. Some species are colonial, building nests on the surface of the ground, while others live as parasites in the nests of other bumblebees.

Unlike the honey-bee, bumblebees are not permanently colonial in temperate regions. Only the queen lives through the winter. When she emerges from hibernation in the spring she builds a nest or occupies an abandoned nest of a bird or mouse, and in it makes waxen cells in which she lays eggs and a waxen honey pot in which to store surplus food. She feeds her young until they mature, and only when they emerge as worker bees does the colony take on an organization like that of the honey-bee. In the fall, males and queens appear and the colonies break up. The queens mate before hibernating. Most authorities include all of these bees in the genus *Bombus.*

The parasitic bumblebees, making up the genus *Psithyrus,* enter the nests of other bumblebees and lay their eggs to be cared for by the hosts. Their chief structural difference is the lack of pollen-gathering organs in the females.

Bumblebees are important in the cross-fertilization of red clover and other deep-throated flowers. (A.W.L.)

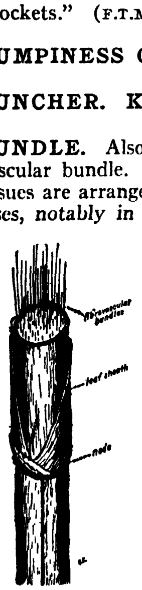
BUMP, AIR. An airplane flying horizontally into an upward gust of air experiences a sudden change of direction of relative wind. This induces a temporary excess of lifting power of the wing which thereby accelerates the airplane upwards. The effect on the occupants is not unlike that of a surface vehicle passing over a bump in the roadway, hence the term "air bump" If the gust is downward, a downward acceleration is produced by the sudden decrease of angle of attack This is sometimes referred to as an "air pocket" because the occupants feel as if the airplane had entered a region in which there was no air to sustain the lift. Actually, of course, there is practically no difference in the density

of air in or out of the regions of air "bumps" and "pockets." (F.T.M.)

BUMPINESS OF AIR. **Turbulence.**

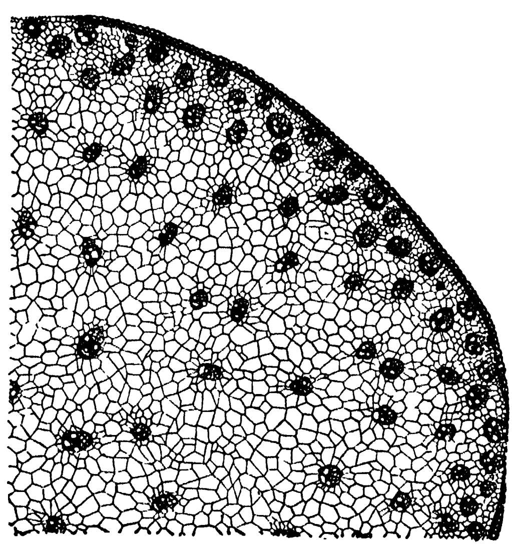
BUNCHER. **Klystron.**

BUNDLE. Also often called vascular bundle or fibro-vascular bundle. In most **vascular** plants the vascular tissues are arranged in the form of a cylinder. In many cases, *notably in woody plants, this cylinder is a solid* mass of cells. But in many plants, particularly in herbaceous **dicotyledons** and **monocotyledons,** the vascular tissues occur in strands which are more or less distinctly separated from one another, and are called vascular bundles. Such bundles appear as discrete objects when seen in a cross-section of the stem. However, they really form a continuous conducting system which extends from a single bundle in the root through the stem and into the leaves and other parts, and becomes an elaborate system of inter-connecting parts.



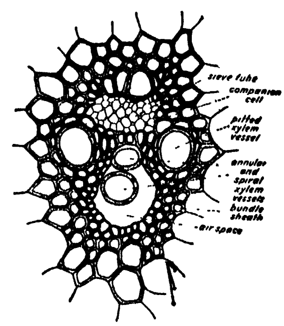
Portion of corn stem (*Zea mays*) with the vascular bundles protruding; illustrating the structure of a typical monocotyledonous stem.

In the axis of the plant each bundle consists of masses of **xylem** and **phloem** cells which may appear in various arrangements; frequently the xylem and phloem cells appear in radially adjoining masses, forming a collateral bundle; less frequently one kind of cells is surrounded by cells of the other kind, forming a concentric bundle; in **roots** a third arrangement is found; the xylem occupies the center of the single bundle, nearly surrounded by strands of phloem. In cross-section the xylem of the young root (see illustration, page 1256) is in the form of a cross with four or five arms (Dicotyledons), or many arms (Monocotyledons), and the phloem strands occupy the positions between the radiating arms of the xylem. Such bundles are called radial bundles.



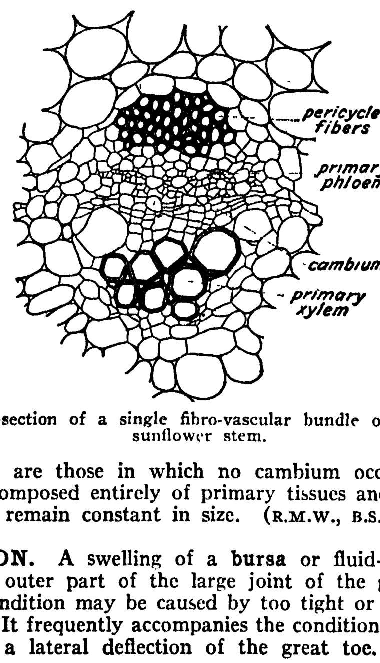
Cross-section of corn stem showing the distribution of fibro-vascular bundles in a typical monocotyledon.

While a bundle consists normally of associated masses of xylem and phloem cells, in many plants there appears with them strands of fibers whose presence may give **protection to the bundle, and additional rigidity to the** stem. Because of the frequent occurrence of such fibrous masses as part of a bundle, the term fibro-vascular bundle has been used to describe them. In many plants the fibrous cells form a mass on the outer side of the bundle, between it and the surface of the stem, while in other plants, particularly in monocotyledons, the fibers form a sheath completely encircling the bundle.



Cross-section of a single fibro-vascular bundle of corn, *Zea mays.*

Bundles are often described as open or closed. Open bundles are those in which **cambium** cells are found, so that by the repeated division of the cambium cells, the size of the bundle constantly increases. Closed bundles are those in which no cambium occurs, they being composed entirely of primary tissues and so once formed remain constant in size. (R.M.W., B.S.M.)



A cross-section of a single fibro-vascular bundle of a young sunflower stem.

BUNION. A swelling of a **bursa** or fluid-filled sac on the outer part of the large joint of the great toe. This condition may be caused by too tight or too short shoes. It frequently accompanies the condition of hallux valgus, a lateral deflection of the great toe. (R.S.M., D.M.H.)

BUNKER. A bunker is any large bin, but its technical meaning is confined to receptacles for the storage of fuel or loose materials in bulk. The bunker is frequently constructed of plate steel which, for some purposes, must be lined with a substance such as **concrete** or wood to protect the metal. One prevalent type, the Berquist suspension bunker, has a profile of such a shape that **tension** is the only **stress** produced in the steel. Since the bunker is usually placed so that the material is deposited from the top, and withdrawn by gravity from the bottom, a suspension type is particularly advantageous. One of the most common uses for bunkers is to hold the coal required for the combustion equipment of **power plants.** It may be able to hold from three to five days' supply for a small plant, but space

limitations will govern the capacity for large power plants. However, the bunker should hold enough to supply the plant during minor repairs to the coal conveying equipment. (F.T.M.)

BUNSEN SCREEN. **Bench Photometers.**

BUNTER SANDSTONE. **Triassic.**

BUNTING. Aves, Passeriformes. Birds (**Aves**) related to the finches and sparrows, including the British yellowhammer, not to be confused with the North American woodpecker which bears this name, the ortolan, and the snow bunting. In North America the indigo bunting, *Passerina cyanea,* is the most widely distributed species, ranging over the eastern half of the country and sometimes to western Texas. The lazuli, varied, painted, and lark buntings are characteristically western birds. The painted bunting, *Passerina ciris,* is also called the nonpareil. (A.W.L.)

BUOY. A buoy is a floating object, usually attached to a specific location on the bottom of the sea or to some submerged object, which is used by navigators. Buoys are used to locate channels, dangerous rocks or shoals, mooring positions, submerged wrecks, and a variety of other purposes The various countries have each devised a system of shapes and colors to be used on buoys for specific purposes. (W.K.G.)

BUOYANCY. The familiar lifting effect of a fluid upon a body wholly or partly submerged in it, known as buoyancy or buoyant force, was first closely studied by the Greek philosopher Archimedes in the 3rd century B.C. What is now known as the "principle of Archimedes" states that the buoyant force is equal to the weight of that body of the fluid which the submerged body displaces, and may be treated as a single force acting vertically upward through the center of gravity of the displaced fluid (center of displacement). This statement applies whether the submersion is partial or complete. The principle readily follows from the consideration that if the submerged body were withdrawn and the resulting cavity allowed to fill with the fluid, the latter would be in equilibrium under the joint action of its own weight and the external forces formerly exerted by the surrounding fluid upon the submerged body.

If the buoyant force equals the weight of the submerged body and acts through its center of gravity, the body will be in equilibrium. This might be true if the body had exactly the same mean density as the fluid. It would then remain at rest when completely submerged at the proper level. A balloon, for example, may rise to a certain height and remain suspended or drift along horizontally. But a solid body completely submerged in a liquid does not come so readily to stable equilibrium, because of the very slight compressibility of liquids, the presence of highly compressible gases in pores of the body or in bubbles clinging to it, and the unequal coefficients of expansion of the body and the liquid.

If, however, the body has a lower mean density than the liquid, it will "float," partly submerged to a level, and in a position with reference to the vertical, determined by the Archimedes principle. An important phase of flotation, especially in ship design, is the degree of stability. This may be expressed in terms of the position of the "metacenter." When a boat is tipped very slightly in a given plane, the center of displacement shifts to one side. There is one point of the boat, called the metacenter, which remains vertically above the center of displacement. This point must be higher than the center of gravity, as the resulting couple then tends to restore the boat to its normal position; if it is lower, the boat is unstable and will capsize. The height of the metacenter above the center of gravity (metacentric height) is a measure of the stability in the given vertical plane. It is in general different for different planes; for example a boat has a transverse and a longitudinal metacenter and metracentric height, corresponding, respectively, to its rolling and its pitching. Thus one may usually change seats in a rowboat without danger, while an equal shift across the boat might overturn it. (See **Weighing Methods.**) (L.D.W.)

BURBLE. Burble describes the action of air over the upper surface of an airfoil when the **angle of attack** has been increased to the point where the air stream no longer follows the profile of the airfoil but breaks away from it. The space between the airfoil and the detached air stream is filled with eddying, burbling air, and the lift is largely lost. The airfoil is then said to have reached the burble point. This is synonymous with "stalled" in wing terminology. (See **Stagnation Point.**) (F.T.M.)

BURBOT. Pisces, Teleostei. The fresh-water representative, *Lota lota,* of the **codfish** family. It is found in streams and lakes of Europe and North America, more commonly north of latitude 40°. The species also goes by the names eel-pout, ling and lawyer. (A.W.L.)

BURDOCK. *Arctium lappa.* **Composite Family.**

BURIN. **Paleontology of Man.**

BURLAP. **Jute.**

BURNER. An arrangement for mixing a **fluid fuel** with air and burning it is called a burner. Burners are commonly provided for liquid and gaseous fluids, but **pulverized coal,** when mixed with a certain amount of air which lubricates it, flows much as a fluid, and is burned by burners. Burner designs for gaseous fuels are the simplest because gas and air are easily mixed and a gas burner may consist of little other than a means to subdivide the total flow of the fuel into a large number of small jets which will present a large surface exposure to the combining oxygen. A liquid fuel will approach the efficiency of gas firing after it is sufficiently atomized or vaporized so as to present a large surface for combustion. This can be done by wicks, by contact with heated metal as in wickless kerosene burners, by the use of high-pressure sprays with very fine holes, or by the use of steam jets. Fuel oil burners of large capacity accomplish an atomization of the oil mechanically by giving the oil a whirl in the burner tip, and discharging it into the furnace through a small orifice. When steam is used, the oil is broken up by a continuous discharge of steam under pressure within the burner and at the tip outlet. Preparation of the oil for use in the burner may include filtering, heating, and pumping. Fig. 1 shows typical oil burners and tips.

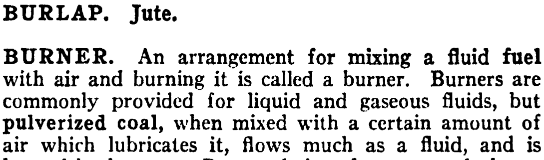


Fig. 1. a. Typical mechanical pressure atomizer tips. b. Typical outside-mixing and inside-mixing steam atomizing burners. (*Handbook of Oil Burning, American Oil Burner Association.*)

Pulverized coal offers much more of a problem in burner design than do oil and gas, even through the coal is pulverized to such an extremely small size that 90% of it will pass through a screen having 100 openings to the inch. Small as the coal particles are, they average 25,000 times larger than the oxygen **molecule.** The pulverized coal is floated or air-borne to the burner on a stream of air amounting to some 10% or 20% of the

total combustion requirements. This is called primary air. The remainder of the air needed, called secondary air, is admitted directly to the burner, the function of which then becomes one of properly proportioning the fuel and air, and thoroughly mixing them. There are two general types of pulverized coal burners, called long and short flame burners. The long flame is produced by moderate tip velocities from a simple form of burner, coupled with an admission of the secondary air through openings in the furnace setting located along the traverse of the flame. Long flame burners are gradually being abandoned in favor of the short flame. The short flame burner produces complete mixture of fuel and air by violently whipping the secondary air through the primary air and fuel. This type is essentially a high-capacity, forced-**draft** type of burner, whereas the long flame burner is better adapted to induced draft.

Fig. 2 shows the primary and secondary air inlets into the short flame burner. The rate of combustion is regu-

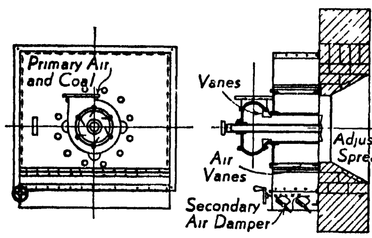

Fig. 2. Circular burner. (*Riley Stoker Corp.*)

lated externally by the rate of feed of coal to the burner. Proper proportioning of air is accomplished by a damper in the secondary air passage. Air vanes cause rotation of the secondary air moving into the furnace. A fan type spreader sets the primary air and coal whirling in the opposite direction. With this turbulence and in the presence of a furnace temperature higher than that required for ignition, the flame will propagate itself back into the incoming air fuel stream at from 15 to 40 ft. per sec. The velocity of the mixture leaving the burner must exceed this in order to prevent flarebacks, and since friction slows down parts of the incoming stream, burner exit velocities of 80 to 130 ft. per sec. are used. (F.T.M.)

BURNISHING. A surface-hardening or surface-finishing process for metals, effected by the application of a roller or blunt rod under pressure to the surface. It is used for gear-tooth finishing to some extent. The work is rotated between three hardened and ground burnishing gears. Burnishing will not correct errors but serves to compress the surface of the teeth and provides a slight surface hardness. As a finishing operation prior to hardening, it can also be used to remove burrs and bruises. (H.C.H.)

BURNS. Burns may be produced by heat, electricity, x-ray irradiation and chemicals. No matter how produced, the injury results in destruction of varying amounts of skin or **mucous membrane** and underlying tissue. Burns are classified according to the depth of the tissue destruction as first, second or third degree, the last being the most severe.

Burns are always serious and frequently fatal when more than a small part of the body surface is involved. The cause of the marked systemic reactions associated with burns is not known, but several factors are believed to be involved. The patient with severe burns exhibits immediately a typical picture of profound **shock,** accompanied by loss of body heat and extreme pain. There is a loss of blood plasma into the burned area, and the surrounding tissues become edematous. A greatly diminished circulating blood volume with a relative increase in **haemoglobin** results. The edema fluid contains a high per cent of chlorides, and there is a corresponding decrease in blood chlorides. The great loss of body fluids plus the low blood chlorides are thought to be responsible for the so-called **toxemia** which severely burned patients show. Infection is a serious complication of burns, and is the cause of many late deaths. Because **bacteria** thrive well in devitalized tissue, the burned area is open to bacterial invasion. Fever, local redness, swelling and eventually pus formation follow. **Kidney** damage and marked **anemia** also occur in severe burns.

The present treatment of burns consists of relieving pain with **morphine,** combating shock by blood or preferably plasma **transfusions,** and preventing infection. Tannic acid has been abandoned because it has been shown to be ineffectual and is thought by some to produce liver and kidney damage.

First and second degree burns do not destroy the regenerative layer of the skin, and consequently heal without scarring. Third degree burns destroy the regenerative layer, and produce marked scarring. This can be minimized by the use of skin grafts, which involves the transplantation of normal skin from some part of the patient's body to the burned area. (D.M.H.)

BURR. 1 A ragged edge of metal particles resulting from cutting or grinding operations. 2. Fine-tooth rotary milling cutters used in die-sinking. (H.C.H.)

BURRO. Mammalia, Perissodactyla. A small variety of the domestic **ass** or donkey, used as a beast of burden in the West. The burro is incredibly tough and subsists on a diet of almost anything edible, hence it has been valuable in the exploration of the more arid areas. (A.W.L.)

BURROWING. The habit of living underground and also the preparation of runways and living quarters beneath the surface. Many animals, such as wolves, that are not specially developed for burrowing, prepare burrows or dens for the birth of their young and for hiding places. Others are normally at home in the ground and come to the surface only under certain conditions; here examples range from the worms, of which the earthworm is particularly well known, to highly specialized mollusks, insects, and vertebrates.

The less specialized burrowing animals cut away the earth by means of structures whose origin is not associated with this use, such as the claws of reptiles, birds, and mammals, while in many of the more specialized forms these parts are highly developed and modified and other special adaptations are evident. The **earthworm** merely eats its way through the earth, and some insects are capable of burrowing into the tissues of plants in the same way. The shipworm, a mollusk, has the valves of the shell adapted for cutting burrows into wood.

The **moles** are highly developed for burrowing by the powerful build of the fore limbs and by their large claws, and are further adjusted to life underground by their fine moisture-resisting fur. The poorly developed eyes are also correlated with conditions underground, since these animals rarely enter the light.

Mole **crickets** are in some ways like the moles. Their front legs are broadened and provided with claw-like processes and the body is covered with a downy vestiture which repels moisture.

Burrowing offers the animal greater safety than can be enjoyed on the surface of the earth, since no predator can compete with the highly developed burrowing animal on equal terms below the surface. (A.W.L.)

BURSA COPULATRIX. A pouch found in the females of some species of **insects** which receives the seminal fluid of the male during copulation, before it passes to the **spermatheca.** (A W.L.)

BURSAE. Small sacs lined with synovial membrane (see **synovia**) which lie near joints. Their function is protective: they act as lubricating buffers between moving parts, between the tendons and bone, or bone and joint capsule, or between skin and bony structures. There are in the neighborhood of 1000 bursae in the human body. (D.M.H.)

BURSITIS. Inflammation of the synovial lining of the **bursae.** This is caused by overuse of a joint, trauma, or infection. Bursitis may be acute or chronic. The acute form is extremely disabling, the involved area being swollen, tender, and very painful on motion. The bursal sac is often distended with fluid in chronic bursitis. Immobilization, heat, and **diathermy** are used in the treatment of acute bursitis; surgery may be necessary in the chronic form.

The common sites for bursitis are the acromial and subdeltoid bursae around the shoulder joint, the olecranon (elbow) bursa, and the pre-patellar bursa ("house-maid's knee"). (D.M.H.)

BUS, AUTOMOTIVE. This automotive term was derived from *omnibus,* a public vehicle for use on public highways, designed to carry a relatively large number of passengers. The present automotive bus represents the outgrowth of a great deal of specialized engineering effort. The service rendered by an automotive bus varies from the comparatively short-haul service for cities and metropolitan areas to the long-distance transcontinental type bus service, and naturally the problems of speed, acceleration from a standstill, passenger comfort, fuel capacity, top speed, etc., will vary.

Since the bus is usually part of a transportation system involving many similar units, specialized overhaul and maintenance service can be worked out applicable to the fleet of buses. Repair centers, emergency stations, etc., may be established by a large system which is then in a much better position to take advantage of new mechanical developments than is the case for the ordinary run of business. Thus a bus transportation system may employ the **Diesel engine** which has been developed to the point of serviceability as a source of automotive power, but whose progress in this field has suffered from the large investment in equipment and talent to build and service the **Otto** type engine. (F.T.M.)

BUSH-CRICKET. Insecta, Orthoptera. **Crickets** of several species, most of which are found chiefly in shrubby vegetation. (A.W.L.)

BUSHING. In mechanical terminology, to bush is to reduce the size of a hole. A bushing is a hollow cylinder used as a renewable liner for a bearing or a drill jig.

A bushing is also a pipe fitting employed to reduce the size of pipe to a smaller size. When pipe is employed to contain electrical wires, the open end from which the wires emerge is often capped by a bushing which substitutes a smoothly rounded surface for the sharp edges of an unbushed conduit. The sharp edges would tend to abraid the insulation on the wires.

In electrical work, where a **conductor** at high voltage emerges from one insulated condition to another, an intermediate support must be provided. An electrical bushing is needed to provide the support and insulation between the conductor and the supporting surface. For example, where the conductor leaves the insulated interior of a **transformer** case, a bushing is provided to support the terminal where it passes through the case, and to insulate the voltage difference between the terminal and the grounded case. A bushing is also required at terminals of oil **circuit breakers,** and at potheads where the conductors of a multi-conductor **cable** are separated and brought out from the cable sheath for external connections. To obtain sufficient dielectric strength for very high voltage bushings without having the physical dimension of the bushing become excessive, the oil-filled bushing or the condenser-type bushing was developed. The condenser bushing is made of thin layers of tin foil wound between concentric layers of **insulation.** It is possible in this way to give uniform potential drop through the thickness of the bushing. (F.T.M., H.C.H.)

BUSHMASTER. Reptilia, Sauria. A large and deadly **snake,** *Lachesis mutus,* found in the forests of Central and northern South America. It is a pit-viper, like the rattlesnakes, water moccasin, and copperhead of North America, but it reaches a length of 12′ and may have fangs over an inch long, hence it is more to be feared than any but the largest of the related species. (A.W.L.)

BUSTAMITE. Rhodonite.

BUSTARD. Aves, Gruiformes. Large birds (**Aves**) of numerous species found chiefly in Africa, although some occur in Europe and Asia. They are chiefly terrestrial in habits but are powerful fliers. One of the African species is called the hubara and those of India are known as floricans. The bustards are related to the rails and cranes. (A.W.L.)

BUSTARD-QUAIL. Aves, Galliformes. *Turnix.* Small birds (**Aves**) related to the pigeons and rails, as well as to the gallinaceous birds. They are widely distributed in the Old World. Also called hemipodes. (A.W.L.)

BUTANOL. Alcohols.

BUTTE. Mesa.

BUTTER. Esters.

BUTTER YELLOW. Dyes.

BUTTERCUP FAMILY. Ranunculaceae. This family, also called the Crowfoot family, is a large family consisting chiefly of perennial herbaceous species distributed throughout the world. It belongs to the order Ranales which is of importance as the most primitive order of Dicotyledons and probably gives rise to the Monocotyledons on the one hand and the two large branches of Dicotyledons on the other. The family is important commercially because it includes many familiar and widely-grown ornamental genera, notably the buttercup (*Ranunculus*), peony (*Paeonia*), larkspur (*Delphinium*), virgin's bower (*Clematis*), and columbine (*Aquilegia*). It also includes the genera *Aconitum* and *Hydrastis,* **aconite** and goldenseal, important medicinal plants. The flowers vary from those having the primitive, symmetrical corolla of the buttercup and peony to those with irregular tubular corollas with long spurs as in columbine and larkspur. *Delphinium* is poisonous to cattle and has been responsible for losses on the western ranges. (P.A.W.)

BUTTERFISH. Pisces, Teleostei. A small species of fish (**Pisces**), also called the gunnel. (A.W.L.)

BUTTERFLY. Insecta, Lepidoptera. An insect with four large wings, usually completely covered with scaly vestiture. Distinguished from most other members of the order (moths and skippers) by the terminal club of the **antennae.** (A.W.L.)

BUTTERWORT. *Pinguicula species.* **Insectivorous Plants.**

BUTT JOINT. Riveted Fastenings.

BUTTRESS. Screw Thread.

BUTTRESS ROOTS. Roots.

BUYS BALLOT'S LAW. Professor Buys Ballot at Utrecht in 1857 stated this law: "Standing with back to wind, low pressure is to left and high pressure to right in northern hemisphere, with the reverse being true in the southern hemisphere." This law was one of the earliest statements of the principles of winds now accepted as common meteorological knowledge. (P.E.K.)

BUTYRIC ACID. Acids, Carboxylic.

BUZZARD. Aves, Falconiformes. Birds (**Aves**) of prey of several species belonging to the genus *Buteo*. The North American representatives are commonly called hawks, as Swainson's hawk. The same may be said of the nearly related rough-legged buzzards; American representatives of the genus are the rough-legged hawks. The name is incorrectly, although commonly, applied to the turkey buzzard, which is a vulture. (A.W.L.)

BY-PASS CONDENSER. This is a condenser placed in an electrical circuit to allow a.c. to flow around some circuit component and cause d.c. to flow through the component. The most common usage is in by-passing various voltage-dropping resistors used in vacuum-tube circuits to adjust the voltages applied to the several parts of the circuits. These resistors are by-passed so there will be no, or very little, alternating signal voltage drop to produce undesirable feedback. The **reactance** of the condenser should be low compared to the **resistance** of the resistor being by-passed. (L.R.Q.)

BYSMALITH. A plug-like **igneous** intrusion related to a laccolith but bounded laterally by faults due to upward "punching" rather than "pushing" of the **magma** as it forces its way into a series of stratified rocks. (R.M.F.)

BYSSUS. An organ of attachment formed by a special byssus gland in the foot of many **bivalve** mollusks. It consists of thread-like processes which are at first adhesive. (A.W.L.)

BYTOWNITE. Feldspar.

C

CAA. Civil Aeronautics Administration. A department of the United States Government, whose duties consist in approving the designs of aircraft to be used in interstate commerce, certifying the airplanes as airworthy, examining and licensing pilots for competence, examining planes in use for continuance of airworthy condition, maintaining federal airway and communications facilities, and engaging in needed aviation research and development. Its position in the federal system has been varied. In 1945 it was found to be a division of the Department of Commerce. (F.T.M.)

CABANE. A cabane is a part of the **airplane** structure. A monoplane which has a wing not attached directly to the fuselage, but mounted above it, requires a cabane structure to carry the load from the wing to the fuselage. A cabane is also needed for the biplane. A cabane is composed of **struts** triangularly framed to remain rigid against fore and aft loads and braced with wire for rigidity laterally. At its upper end it is connected to the wing root fittings and at its lower end to the fuselage. If the main structural members of the wing are not continuous from tip to tip the outboard sections are hinged at the cabane joint, and there is a short center section. (F.T.M.)

CABBAGE. **Brassica.**

CABBAGE BUTTERFLY. Insecta, Lepidoptera. A white **butterfly,** *Pieris rapae,* with black-tipped forewings and two or three black spots on the wings of each side. Introduced from Europe about the middle of the nineteenth century, this species spread rapidly until at present it is found throughout the United States and much of Canada. The caterpillar feeds on all cruciferous plants, but is especially important as a pest on cabbage and cauliflower, whence it receives its common name.

The insect can be held in check by spraying with Paris green. Cabbage heads formed on sprayed plants do not contain enough poison to affect human beings. (A.W.L.)

CABINET REPRESENTATION. **Pictorial Representation.**

CABLE. A cable is a strong rope composed of several strands of fiber or wire. In nautical terms, large ropes usually 10″ or more in circumference are known as cables, while smaller ropes are called hawsers. However, by common usage, a cable is any strong rope. Structural cable, made of straight or twisted steel wires, is used for suspension **bridges.** Twisted wire cables are also used as guy lines and lifting lines for some types of **derricks.** (See **Cable, Electrical.**) (F.T.M.)

CABLE, ELECTRICAL. An electrical cable is one or more conductors surrounded by an insulating medium and a protective sheath. Such cables are used for the transmission of electric power and for transmission of communication signals. The power cables have relatively few conductors of heavy gauge and are insulated for high voltages. Such cables are frequently filled with oil to increase the insulation strength. The outer sheath is commonly of lead, although for submarine work this in turn is often further strengthened by a second sheath of steel strands. Communications cables usually contain many pairs of small-gauge copper conductors, paper-insulated, surrounded by a lead sheath. Sometimes the entire cable is nitrogen-filled under pressure. The various pairs of conductors are arranged by twisting and placing to minimize pick-up between them (see **Cross-Talk**). Common practice is to include two extra pairs for spares for each hundred active pairs. Cables used for submarine circuits have fewer pairs and are heavily insulated and armored to withstand the severe strains to which they may be subjected in laying and by ocean currents. The coaxial cable is a special type in which the pair of conductors is formed by a center wire and the outer sheath. In this case the sheath is copper and the insulation is often a gas with solid dielectric spacers at intervals to hold the inner conductor centered. This coaxial cable may in turn be enclosed with others in a lead sheath for protection. Coaxial cables have a wide usable frequency range and hence are used for transmission of television programs. They are also often used for radio-frequency transmission lines as they have no external field. (L.R.Q.)

CABLEWAY. A suspended steel **cable** acting as a track for aerial hoisting and conveying devices is a cableway. While occasionally used for transporting persons across deep gorges, where the amount of traffic does not warrant the building of a **bridge,** the cableway, in its more common application, handles construction material for building of **dams,** etc., or has a permanent use in connection with the handling of material such as rock or gravel which is taken from open pits. Clear spans up to a half-mile in length are possible in a cableway. The carriage which operates on the cableway may or may not have provision for carrying pasengers, depending on the purpose of the cableway. (F.T.M.)

CACAO. **Esters; Theobroma Cacao.**

CACHALOT. Mammalia, Odontoceti. A name for the sperm **whale** from the French. *Physeter catodon.* (A.W.L.)

CACHEXIA. A state of extreme malnutrition with resultant weakness and wasting of body tissues. It is frequently seen in the terminal stages of chronic disease —particularly **cancer.** (D.M.H.)

CACOMISTLE. Mammalia, Carnivora. Small animals related to the raccoons but of more slender build. Several species, ranging from Mexico to Oregon. Also called **civet cat** and ring-tailed cat. (A.W.L.)

CACTUS FAMILY. Cactaceae. The cactus is known to all as a prickly inhabitant of dry American deserts. In popular parlance, the name "cactus" applies to any fleshy spine-covered plant. But not all spiny plants are cacti, nor are all cacti characterized by spines.

With the exception of a single genus *Rhipsalis,* some of whose members are said to occur in Ceylon and Madagascar, all cacti are natives of America, where they are found widely scattered from latitude 59° in North America through the tropics to the southern Andean region and Argentina. They are particularly conspicuous features of the flora of dry desert regions where they are found in a wide variety of forms and sizes.

A few genera, and especially *Pereskia,* are very like ordinary **mesophytic** plants, having well-developed ovate leaves borne alternately on a long slender stem. But in nearly all of the Cactus Family the leaf surface is very much reduced, the leaves appearing as small fleshy bodies which last but a brief time before dropping off. In

many species leaves of any recognizable kind are never formed, the green fleshy stem taking over the function of leaves completely. In these fleshy stems large amounts of water are stored, a feature which enables these plants to survive in the arid regions in which they so frequently grow. Due to the mucilaginous nature of the cell contents and to the greatly reduced surface of the plants the contained water is held most tenaciously and lost very slowly.

In their natural environment cactus plants have an extensive system of long fibrous roots which not only extend outward from the plant to considerable distances, but also penetrate the soil deeply. In cultivated plants the root system is usually greatly reduced. The stems of cacti show a variety of forms. In addition to the normal-stemmed *Pereskia,* there are the Prickly Pears, species of *Opuntia.* In most of these the stem is a series of flattened, fleshy joints often abundantly protected with bristling bunches of barbed spines. In species of *Mammillaria* and *Cereus* the stem is a cylindrical or globular body, often conspicuously ridged, and armed with numerous spines. In *Phyllocactus* and *Epiphyllum* the stem is flattened and largely unarmed, the small weak spines being borne in notches along the edges of the stem. The familiar night-blooming "cereus" is of this type.

One of the best known and largest of all the cacti is the sahuaro or giant cactus (*Cereus giganteus*). This species is a native of southern Arizona, northern Sonora, and extreme southeastern California. This massive cactus may grow to a height of 50′ with many side branches. Some individuals probably attain an age of 200 years. In some parts of its range extensive "forests" of this species have developed.

The flowers of most species of cactus are large and brightly colored. They are regular, although in some species a definite tendency toward zygomorphic **flowers** is seen The flowers are borne singly. The **perianth** is composed of a large number of separate members which show a gradual transition from the outer small sepals (see **Flower**) through to large brightly colored petals. The stamens are likewise numerous and have long filaments. The single compound pistil contains many ovules and in fruit becomes a many-seeded berry. In many species the fruit is edible. Species of *Opuntia* are frequently planted in rows to form an impenetrable barrier against intruders. These plants were early introduced into the Old World and later into Australia, where in many places they have become a troublesome and almost worthless weed. Cactus plants are frequently seen in cultivation, being especially sought by those who like the bizarre effect they give. Somewhat similar in appearance are many species of *Euphorbia* from tropical Africa, and of *Stapelia,* a genus of the Milkweed Family, and likewise native to Africa. The flowers of these plants are quite unlike cactus flowers, however, so that the plants are readily distinguished when they bloom.

One genus of cactus, the Living Rock Cactus, *Lophophora williamsii,* is used by the native American Indian to produce a state of extreme exhilaration. It is used in the form of dried disks or buttons, sections of the stem, known as peyotl or mescal, a curious-tasting object which gives to the user the most agreeable sensations of color and pleasure. While it is not habit-forming, its use is frowned upon by Americans. (R.M.W., B.S.M.)

CADDIS OR CADDICE FLY. Insecta, Trichoptera. The adult of any species of this order. The caddis flies are slender **insects** with four wings, sometimes clothed with hair-like scales which give them a moth-like appearance. The mouth parts are formed for biting but are vestigial. Since the **larvae** are aquatic the caddis flies are much more abundant in the vicinity of water, but they are attracted to light, often at some distance. (A.W.L.)

CADDIS WORM. Insecta, Trichoptera. The aquatic larva of a **caddis fly.** They are noteworthy for the silken webs and cases which they build, some for protection and some to catch prey. Some species spin silken nets attached to rocks in the bottom of a stream in such a position that the current washes into the wide mouth and passes out through a web at the smaller end. In this way the **insect,** which lives in a tube near by, snares its food. Many of the caddis worms live in cases from which only the head and legs protrude. These cases are formed of many different materials, held together by silk. Some are made of small flat pebbles. some of bits of leaves, and some of small snail shells. They are economically of some value as food for fishes. (A.W.L.)

CADELLE. Insecta, Coleoptera. A small brown **beetle,** *Tenebroides mauritanicus,* which infests granaries, feeding on other insects as well as on grain.

Fumigation with **carbon disulfide** and **hydrocyanic acid** gas has been used to destroy this and other granary pests. Both methods are dangerous and should be employed only by experts. It has been found effective also to heat the entire building to a temperature of 120–140° F. for several hours. In mills which have heating plants of ordinary efficiency for winter use these temperatures can be secured in the summer. (A.W.L.)

CADMIUM. Symbol: Cd. Atomic number: 48. Atomic weight: 112.41. Density: 8.6. Hardness: 2. Melting point: 320.9° C. Boiling point: 767° C. (**Isotopes**: page 290.)

Cadmium is a silver-white metal, malleable and ductile, but at 80° C. becomes brittle, remaining lustrous in dry air and only slightly tarnished by air or water at ordinary temperatures, may be sublimed in a vacuum at a temperature of about 300° C., when heated in air burns to form oxide, dissolves slowly in hot dilute **hydrochloric** or **sulfuric acid,** and more readily in **nitric acid.** Discovered by Stromeyer in 1817.

Cadmium metal is used (1) as a protective coating for iron and steel, (2) in alloys such as solder, "bearing metal," and low melting point "fusible" alloy.

Cadmium occurs as the sulfide (**greenockite,** CdS) in Greenland, Scotland and Pennsylvania, but chiefly in zinc ores (frequently 1 part cadmium to 400 parts zinc), from which it is separated during the process of manufacture by fractional distillation—cadmium is more volatile than zinc and is collected in the initial distillate.

Bromide. Cadmium bromide ($CdBr_2$), white soluble solid. Used in photography.

Chloride: Cadmium chloride ($CdCl_2 \cdot 2\frac{1}{2}H_2O$), white soluble crystals by reaction of cadmium metal and **hydrochloric acid,** and crystallizing.

Hydroxide: Cadmium hydroxide ($Cd(OH)_2$), white precipitate by the reaction of cadmium salt solution and **sodium** hydroxide solution; soluble in acids and in ammonium hydroxide, but insoluble in sodium hydroxide solution.

Nitrate: Cadmium nitrate ($Cd(NO_3)_2 \cdot 4H_2O$), white, soluble crystals, by reaction of cadmium metal and **nitric acid,** and crystallizing.

Oxide: Cadmium oxide (CdO), brownish-yellow solid, by burning cadmium metal in air, or by ignition of cadmium hydroxide, carbonate or nitrate.

Iodide: Cadmium iodide (CdI_2), white, soluble solid, by reaction of cadmium oxide, hydroxide, or carbonate with **hydriodic acid,** soluble in alcohol (most iodides are insoluble in alcohol), forms cadmium potassium iodide, soluble, by excess of potassium iodide and crystallizing.

Sulfate: Cadmium sulfate ($3CdSO_4 \cdot 8H_2O$), white soluble solid, by reaction of cadmium metal and dilute **sulfuric acid,** and crystallizing. Used in making the Weston standard electromotive force cell.

Sulfide: Cadmium sulfide, "cadmium yellow" (CdS), yellow precipitate, by reaction of cadmium salt solution and **hydrogen sulfide.** Used as a yellow paint pigment and when mixed with ultramarine for green pigment, in coloring soap, paper and rubber, and in ceramic glazes.

Tungstate: Cadmium tungstate ($CdWoO_4$), yellow insoluble solid. Used in fluorescent paint. (R.K.S.)

REPRESENTATIVE ALLOYS CONTAINING CADMIUM

Fusible alloy, melting at 145° C	18% Cd	50% Sn	32% Pb	
Fusible alloy, melting at 70° C. (Wood's metal)	12 5% Cd	50% Bi	25% Pb	12 5% Sn
Fusible alloy, melting at 70° C. (Lipowitz' alloy)	10% Cd	50% Bi	27% Pb	13% Sn
Fusible alloy, melting at 91.5° C.	8% Cd	52% Bi	40% Pb	
Alloys melting at:				
420° C	90% Cd	10% Ag		
610° C	70% Cd	30% Ag		
760° C.	50% Cd	50% Ag		
280° C.	90% Cd	10% Zn		
295° C	70% Cd	30% Zn		
327° C	50% Cd	50% Zn		

(R.K.S.)

CADUCEUS. The wand of Hermes, or Mercury, used as a symbol of the medical profession and of the Medical Corps of the U. S. Army. (R.S.M.)

CAECILIA. **Gymnophiona.**

CAECUM. Any blind pouch, especially a sac-like appendage of the alimentary tract (see **Anatomy**). The blind pouch with which the large intestine begins is a caecum; it bears the vermiform appendix in man and the anthropoid apes. Some of the fishes have **pyloric** caeca at the point of union of the stomach and intestine and in some insects the rectum bears such pouches. A pair of blind branching diverticula associated with the vestigial intestine of the starfishes are called rectal caeca. (A.W.L.)

CAESAREAN SECTION, OPERATION. Removal of the child from the **uterus** by means of an incision through the abdominal and uterine walls.

It is generally thought that Julius Caesar was born in this way and that he obtained his name from the manner of his delivery (a *caeso matris utero*). However, this could hardly be correct since his mother lived for many years after his birth and also Julius was not the first to have the name Caesar. The correct derivation of the name for the operation comes from the Roman law by which it was required that such an operation be performed upon women who died just before the termination of pregnancy. At first this law was known as the *lex regia* but under the emperors its name was changed to the *lex caesarea* and the operation henceforth was known as the caesarean operation.

As to when the first caesarean operation was performed on a living woman there is no definite information, although certain passages in the Talmud may indicate that it was carried out in the early Christian era.

The first record of an authentic caesarean operation on a living woman was in 1610 by Trautmann, of Wittenberg. There were probably other operations done before this but we have no record of them. Up to 1882 no sutures were used in the incision in the pregnant uterus and most of the women perished from hemorrhage. Even after sutures were used the mortality was so great from **peritonitis,** shock, and hemorrhage, that in 1887 out of 11 operations performed in New York City only one mother survived. Since then, however, with improvements in the whole field of surgery, the operation has become relatively safe. The mortality at present in the hands of capable surgeons is very low.

The operation is performed under the following circumstances: 1. When there is deformity and narrowing of the bony pelvis which does not permit delivery through the vaginal route. 2. If a pelvic **tumor** blocks the birth canal. 3. In certain patients with advanced heart disease, **tuberculosis, nephritis** and other conditions which may make labor dangerous to the health of the mother. 4. In patients who have previously been delivered by caesarean section. (R.S.M., D.M.H.)

CAFFEINE, OR TRIMETHYLXANTHINE. An **alkaloid** prepared usually from **tea**-leaves. It is present also in **coffee,** Kola and guarana. It is a frequently used and valuable drug in medicine, where it serves as a stimulant and **diuretic.** (R.S.M.)

CAFFRE CAT. Mammalia, Carnivora. A **cat** which ranges throughout Africa and into Asia. It resembles the domestic cat and is supposed to represent the ancestral stock from which some strains of the latter are derived. (A.W.L.)

CAGE. **Bearings.**

CAIMAN. Reptilia, Crocodilia. *Caimein.* Large **reptiles** of five species inhabiting the waters of Central and tropical South America. They resemble the crocodiles but are less dangerous. Called by the natives jacare. (A.W.L.)

CAIRNGORM STONE. The name given to the smoky brown variety of **quartz,** particularly when transparent, from Cairngorm, Scotland, a well-known locality. (E.S.C.S.)

CAISSON. A caisson is a large, usually bottomless box or cylindrical shell, made of wood, **concrete** or **steel,** which is used in the construction of **foundations** located in water or below the ground-water level. It is also useful when quicksand or other unstable soils are encountered during the excavation for a deep foundation. Caissons for the foundations of buildings or other land structures are forced down through the soil by means of weights while the underlying material is being excavated. A water jet is often used to aid the sinking action of the weights by reducing friction and by breaking up the material under the edge of the caisson. As the sinking progresses additional sections are added until the required depth is obtained. When the foundation is to be constructed under water, the caisson is built on land, floated to the site and sunk in place by means of weights. If it is to be sunk to bed rock through the mud or sand at the bottom of the body of water, the operation is carried on in a manner similar to that described for building caissons. In order to withstand **hydrostatic** or earth pressure the caisson should be properly braced or reinforced.

The box caisson is a water-tight structure used for **bridge** foundations which are under water. It is open at the top so that concrete or stone may be deposited to provide the necessary weight to sink it to the correct position, the bottom having been previously prepared so that a firm footing is assured.

An open caisson is a rectangular or cylindrical shell, usually open top and bottom, although it may have a bottom with wells for removing the excavated material. It is provided with a cutting edge to penetrate the underlying soil and thus facilitate the sinking operation. Double walls or **ballast** pockets are used so that at least a part of the permanent filling may be placed subsequent to sinking and in this way reduce the amount of temporary loading. In land operations the bottom of the caisson is assembled over the site of the foundation and the earth within the walls excavated. As the material is removed the weight of the caisson and the additional loads, if required, cause it to sink. The water jet, whose action has been described, may be used to assist

gravity action. When the caisson reaches its final position and the remaining earth has been excavated, a concrete seal is poured through the water that is in the bottom of the caisson. This makes the bottom watertight. The water is then pumped out and the interior filled with concrete. Open caissons may be used for bridge piers if they are constructed in such a manner that the upper end projects above the surface of the water. The depth of the seal must be large enough to provide a mass of concrete that will counteract the effects of the uplift of water which may seep through the sand or mud at the bottom of the caisson. If the depth of the concrete seal is made about one-half the depth of the water, measured from the surface to the bottom of the caisson, the caisson will be safe against flotation, even for 100% unlift. Open caissons are generally used for deep building foundations which are carried below the ground-water level. The depth to which the shell may be sunk depends upon the friction developed on the sides and upon the material which is encountered. This type of caisson has several disadvantages. The character of the bottom cannot be readily ascertained due to the fact that it is under water; the bearing area cannot be properly prepared to receive the caisson and the concrete seal must be placed under water. It also has some advantages. The use of compressed air, which is a necessary factor of the pneumatic caisson, is not required. It may be used for greater depths than the pneumatic caisson when the ground-water level is high and for some types of foundations it is more economical. The genesis of the open caisson method was originated and developed by the Chinese probably as early as 1500 B.C. in connection with the sinking of shallow wells in soft material where other methods of construction were unsuitable or impractical. In modern times this ultimately led to the development of the pneumatic caisson.

The pneumatic caisson consists of an inverted box or cylinder which utilizes compressed air to counteract the hydrostatic pressure. The essential parts of the caisson are a working chamber, open shafts and **air locks**. The working chamber is the place where excavation is carried on under compressed air. The shafts provide a means for workmen to enter or leave the caisson and are also used as outlets for the excavated material. The air lock is a room where the air pressure is gradually adjusted as the workmen enter or leave the working chamber. When the pneumatic caisson is to be used for land foundations, where the water level is high, the bottom containing the working chamber is constructed first. This bottom has a cutting edge similar to that for the open caisson. The material in the working chamber is dredged out and the caisson gradually sinks into the soil. When the ground water is encountered compressed air must be used to keep the water out of the working chamber, and as the sinking progresses, the pressure must be increased to balance the hydrostatic pressure. As the caisson is lowered **cofferdams** are used to keep out earth or water. Concrete, which is deposited inside the cofferdam, furnishes additional weight for sinking. After the caisson has reached its final resting place all loose material is excavated. A concrete seal is then used to exclude water. The air pressure is reduced to atmospheric pressure, the air locks removed and the remainder of the working chamber and shafts filled with concrete. Pneumatic caissons, used for foundations located in water, are usually built on shore and floated into position. If the top is made air-tight the air in the working chamber will add to the buoyancy. Additional buoyancy may be obtained by means of a temporary water-tight and air-tight bottom. The sinking of the caisson through the water is accomplished by pouring concrete inside the walls of the cofferdam. When the caisson reaches the bottom the procedure is similar to that described for the pneumatic caisson sunk through earth. The sinking of the pneumatic caisson may be controlled more readily than that of the open caisson. Obstructions such as boulders or sunken logs can be easily removed and the surface under the caisson properly prepared and inspected. The concrete seal does not have to be poured through water as in the case of the open caisson. One serious objection is that the depths is controlled by the fact that there is a limit to the intensiy of the air pressure in the working chamber which workmen can stand safely. (C.W.C.)

CAISSON DISEASE (COMPRESSED AIR ILLNESS, "THE BENDS," DIVER'S PALSY). This disease occurs in individuals who, having been exposed to increased air pressure, are subjected to too abrupt reduction in the pressure.

At present, with engineering operations in digging tunnels and underwater supports, and in deep-sea diving, there are numerous opportunities for this disease. Great precautions, however, are taken to prevent its occurrence. On entering or leaving the caisson where air pressures of 30 to 40 lbs. are present, air locks are provided where gradual compression and decompression are produced. In spite of these precautions a number of cases of caisson sickness develop. The same disease occurs from rapid ascension to a great height, as in high-altitude flying. Descent to a higher air pressure relieves all symptoms.

The cause of this disorder is the rapid liberation of nitrogen from the fluids and tissues of the body in going too rapidly from high to low pressures. The presence of this nitrogen is due to the increased solubility of the gas under the higher pressures as in the caisson. The liberated gas forms bubbles in nerve tissue, muscles, brain, and other body tissues.

The symptoms produced are localized pain in the abdomen or extremities, vertigo, sensory or motor disturbances, dyspnea, collapse and unconsciousness.

Cases treated early usually make a complete recovery. Those that reach the stage of collapse usually do not recover.

The only treatment is recompression and slow decompression. The victim is placed as quickly as possible in an air lock and the air pressure increased until all the air bubbles go into solution. The pressure is then very gradually lowered until normal air pressure is realized. (R.S.M., D.M.H.)

CALAMARY. Mollusca, Cephalopoda. The true squids, *Loligo*, including the common squid of the Atlantic Coast and related species. (A.W.L.)

CALAMINE. The mineral calamine is **zinc** silicate (H_2ZnSiO_5) occurring in tabular and prismatic **orthorhombic** crystals although often in massive and fibrous forms. There is a perfect cleavage parallel to the prism; it is brittle with a sub-conchoidal fracture; hardness, 4.5–5; specific gravity, 3.40–3.50; luster, vitreous; color, white, tending toward light bluish or greenish shades; streak, white; transparent to translucent. Calamine differs from **willemite**, also a zinc silicate, in that the former contains considerable water which may be driven off when heated to a high temperature.

There are many localities for calamine in Europe, fine specimens having come from Saxony, Sardinia; Cumberland, Alston Moor and Derbyshire, England. It is found in Siberia, Algeria and Mexico. In the United States calamine has been found at Sterling Hill, New Jersey; in Lehigh County, Pennsylvania, and in Virginia, Missouri, Montana, Colorado, Utah, New Mexico and Nevada.

The name calamine is said to have been derived from the Latin *calamus*, a reed, in reference to its occurrence in slender stalactitic forms. It is an important ore of zinc.

Calamine has also been called **hemimorphite** because of the tendency to form doubly terminated crystals show-

ing a different grouping of faces at either end. The name is derived from the Greek meaning half and form. (E.S.C.S.)

CALAMITES. **Paleobotony.**

CALAMISTRUM. A comb-like structure on the fourth leg of some **spiders**. It is formed of stiff hairs and is used to manipulate silk for certain purposes. (A.W.L.)

CALANDRA. Aves, Passeriformes. A European **lark**, noted for its song. The name is sometimes applied to other related species of the Old World. (A.W.L.)

CALANDRIA. The part of a vacuum-evaporating apparatus wherein the liquid being concentrated is circulated through tubes that are surrounded by steam to furnish heat. (R.K.S.)

CALAVERITE. **Sylvanite.**

CALCAREA. A class of the phylum **Porifera** containing **sponges** whose spicules are calcareous. They are marine animals exclusively.

The sponges of this class include the simplest of the entire phylum. Some are of the ascon type, with canals passing completely through the body wall, and others are sycon sponges with two sets of canals, the incurrent leading into the body wall from the exterior and the radial leading from the body wall to the interior of the sponge. Common sponges are available to illustrate both forms, *Leucoselenia* representing the former and *Grantia* the latter. These structural differences and the examples mentioned characterize the two orders into which the class is divided:

Order Homocoela. Ascon sponges; *Leucoselenia*.
Order Heterocoela. Sycon sponges; *Grantia*. (A.W.L.)

CALCAREOUS. **Limestone.**

CALCAREOUS ALGAE. **Paleobotany.**

CALCAREOUS TUFA. **Tufa.**

CALCIFEROUS GLAND. **Oesophageal Gland.**

CALCINATION. The process of calcination involves the subjection of a substance to a high temperature below its **fusion** point, usually to make the substance friable. Material so treated may (1) lose moisture, e.g., the heating of **silicic acid** or **ferric** hydroxide resulting in the formation of silicon oxide or ferric oxide, respectively, (2) lose a volatile constituent, e.g., the heating of **limestone** (calcium carbonate) resulting in the formation of **carbon dioxide gas** and **calcium** oxide residue—destructive distillation of many organic substances is of this type—(3) be oxidized or reduced, e.g., the heating of pyrite (iron disulfide) in air resulting in the formation of **sulfur dioxide** gas and ferric oxide residue. When the calcination involves oxidation, as in the preceding case, the operation is termed roasting. When heating involves reduction of metals from their ores, with separation from the gangue of the liquid metal and slags the process is termed smelting. (See **Smelting.**) (R.K.S.)

CALCIPHILE. Plants which require an abundance of **calcium** in the soil for satisfactory growth are known as calciphiles. Many important agricultural plants, as for example **alfalfa** and many of the clovers, are of this sort. This has led to the practice of liming the soil when these crops are planted. (R.M.W.)

CALCIPHOBES. Plants which cannot tolerate **calcium** are called calciphobes. Such plants, moreover, prefer an extremely acid soil. Members of the heath family are of this group. Rhododendrons, for instance, so admired for their beautiful showy flowers and thick evergreen leaves, often fail to grow satisfactorily due to an excess of lime or calcium in the soil. Working into the soil around the plants an abundance of leaves often helps to correct this condition. The effect may be due to the toxic action of the calcium, or may be because the calcium prevents the absorption of other elements necessary to the plant. (R.M.W.)

CALCITE. The mineral calcite, **carbonate of calcium** corresponding to the formula $CaCO_3$, is one of the most widely distributed minerals. Its crystals are **hexagonal-rhombohedral** although actual calcite rhombohedrons are rare as natural crystals. However, they show a remarkable variety of habit including acute to obtuse rhombohedrons, tabular forms, prisms, or various **scalenohedrons.** It may be fibrous, granular, lamellar or compact. The cleavage in three directions parallel to rhombohedron is highly perfect; fracture, conchoidal but difficult to obtain; hardness, 3; specific gravity, 2.7; luster, vitreous in crystallized varieties; color, white or colorless through shades of gray, red, yellow, green, blue, violet, brown, or even black when charged with impurities; streak, white; transparent to opaque; it may occasionally show phosphorescence or fluorescence. Calcite is perhaps best known because of its power to produce strong **double refraction** of light such that objects viewed through a clear piece of calcite appear doubled in all of their parts. A beautifully transparent variety used for optical purposes comes from Iceland, for that reason being called Iceland spar.

Acute scalenohedral crystals are sometimes referred to as dogtooth spar.

Calcite represents the stable form of calcium carbonate; aragonite will go over to calcite at 470° C.

Calcite is a common constituent of **sedimentary** rocks, as a vein mineral, and as deposits from hot springs and in caverns as stalactites and stalagmites.

Among many localities noted for fine crystals of calcite are: Saxony; Cumberland, England; Guanajuato, Mexico; St. Lawrence County, N. Y.; West Paterson and Bergen Hill, N. J.; and Joplin, Mo. (E.S.C.S.)

CALCIUM. Symbol: Ca. Atomic number: 20. Atomic weight: 40.08. Density: 1.54. Hardness: 1.5. Melting point: 810°. Boiling point: 1170° C. Isotopes: 40 (96.76%), 42 (0.77%), 43 (0.17%), 44 (2.30%).

Calcium is a silver-white metal, somewhat malleable and ductile; stable in dry air but in moist air or with water reacts to form calcium hydroxide and hydrogen gas; when heated burns in air to form calcium oxide emitting a brilliant light. Discovered by Davy in 1808.

Calcium occurs generally in rocks, especially limestone (average 42.5% CaO) and igneous rocks (average 5.0% CaO); as the important minerals **limestone** (calcium carbonate, $CaCO_3$), **gypsum** (calcium sulfate dihydrate, $CaSO_4 \cdot 2H_2O$), **phosphorite,** phosphate rock (calcium phosphate, $Ca_3(PO_4)_2$), apatite (calcium phosphate-fluoride, $Ca_3(PO_4)_2$ plus CaF_2), **fluorite,** fluorspar (calcium fluoride, CaF_2); in bones and bone ash as calcium phosphate, and in egg shells and oyster shells as calcium carbonate. Calcium is the fifth element in abundance, constituting 3.6% of the earth's solid shell; is the most abundant metallic element of the human body (2.0% Ca), is the third most abundant metallic element of vegetation (0.6% Ca, exceeded by potassium and by sodium).

Calcium metal is produced in small amount by **electrolysis** of anhydrous fused calcium chloride, finding a limited use as a reducing metal, and alloyed with lead (0.04% Ca) for sheathing electric cables. Calcium compounds are among the most common metallic compounds encountered in industry.

Acetate: Calcium acetate, "acetate of lime," "lime pyrolignite" ($Ca(C_2H_3O_2) \cdot H_2O$), white solid (technical

is "gray" or "brown"), solubility: at 0° C., 27.2 grams; at 40° C., 24.9 grams, at 80° C., 25.1 grams of anhydrous salt per 100 grams saturated solution, formed by reaction of calcium carbonate or hydroxide plus **acetic acid.** (A common source of acetic acid is "pyroligneous acid," a crude product from wood distillation.) Used (1) as one of the sources of acetic acid, (2) as one of the sources of acetone, (3) in dyeing and printing cotton goods.

Aluminates: Calcium aluminates, four in number, have been prepared by high temperature methods and identified ($3CaO \cdot Al_2O_3$, at 1535° C. decomposes with partial fusion; $5CaO \cdot 3Al_2O_3$, melting point 1455° C.; $CaO \cdot Al_2O_3$, melting point 1590° C.; $3CaO \cdot 5Al_2O_3$, melting point 1720° C.). These aluminates are important in connection with Portland cement.

Aluminosilicates: Calcium aluminosilicates, two in number, have been prepared by high temperature methods and identified ($2CaO \cdot Al_2O_3 \cdot SiO_2$, gehlinite; $CaO \cdot Al_2O_3 \cdot 2SiO_2$, anorthite). Calcium aluminosilicate mixtures are important in connection with Portland **cement,** and metallurgical **slags.**

Arsenate: Calcium arsenate, arsenate of lime ($Ca_3(AsO_4)_2$), white precipitate, formed by reaction of soluble calcium salt solution and **sodium** arsenate solution. Used as an insecticide.

Arsenite: Calcium arsenite, arsenite of lime ($Ca_3(AsO_3)_2$), white precipitate by reaction of soluble calcium salt solution and **sodium** arsenite solution. Used as an insecticide and germicide.

Borates: Calcium borates are found in nature as the minerals **colemanite** ($Ca_2B_6O_{11} \cdot 5H_2O$), **borocalcite** ($CaB_4O_7 \cdot 4H_2O$), and pandermite ($Ca_2B_6O_{11} \cdot 3H_2O$).

Bromide: Calcium bromide ($CaBr_2 \cdot 6H_2O$), white solid, soluble, formed by reaction of calcium carbonate or hydroxide plus **hydrobromic acid,** and then evaporation. Used in medicine and in photography.

Carbide: Calcium carbide, "carbide" (CaC_2), grayish-black solid, reacts with water yielding **acetylene** gas and calcium hydroxide, formed at **electric furnace** temperature from calcium oxide plus **carbon** (coke). Used as the starting point for many organic chemicals (1) from acetylene, (2) from calcium cyanamide.

Carbonate: Calcium carbonate ($CaCO_3$), found in nature as **calcite,** Iceland spar, marble, limestone, coral, chalk, shells of **mollusks, aragonite.** This is the most widely distributed compound of calcium in nature, and the source of calcium for many manufacturing processes, since it is (1) readily dissolved by acids forming the corresponding calcium salt, (2) converted to calcium oxide upon heating. Aragonite is an unstable form at room temperature, although no change is observable until heated, when at 470° C. it is quickly converted into calcite; calcium hydrogen carbonate, calcium bicarbonate, $Ca(HCO_3)_2$, colorless solution, formed by reaction of calcium carbonate and carbonic acid, either in a test tube or in limestone regions where this action accounts for the caves and holes encountered. When the solution loses carbon dioxide by exposure to air or by warming, calcium carbonate is precipitated, e.g., in steam boilers or stalactites and stalagmites of limestone caves.

Chloride: Calcium chloride ($CaCl_2 \cdot 6H_2O$), white solid, soluble, absorbs water from moist air, formed by reaction (1) of calcium carbonate or hydroxide plus **hydrochloric acid,** and then evaporation, (2) of calcium hydroxide plus ammonium chloride in the reaction for the production of ammonia gas. The latter is the commercial source, where calcium chloride is a final product of the "ammonia-soda" process for **sodium** carbonate. Obtainable commercially as fused anhydrous, and as flakes. Used as dust preventative, as brine for refrigeration, in freezing mixtures and solutions, as a drying agent for gases (not ammonia), as a dehydrating agent, as a wood preservative.

Chromate: Calcium chromate ($CaCrO_4$), yellow solid, soluble, formed by the reaction of chrome iron ore and calcium oxide heated to a high temperature in a current of air and then extraction with water. Used as a pigment.

Citrate: Calcium citrate ($Ca_3(C_6H_5O_7)_2 \cdot 4H_2O$), white solid, solubility: at 18° C. 0.085 gram crystals per 100 grams of water, at 30° C. 2.2 grams, former by reaction of calcium carbonate or hydroxide plus **citric acid** solution. Used in effervescent beverages.

Cyanamide: Calcium cyanamide ($CaCN_2$), white solid, formed (1) by fusing cyanamide or urea with calcium oxide, sublimes at 1050° C., (2) industrially, by heating calcium carbide at 1100–1200° C. in a current of **nitrogen.** The mass is black due to the separation of carbon. Used (1) as a nitrogenous **fertilizer,** (2) as the starting point for the manufacture of various organic chemicals, and sodium cyanide.

Fluoride: Calcium fluoride, **fluorite,** fluorspar (CaF_2), white precipitate, formed by reaction of soluble calcium salt solution plus **sodium** fluoride solution. Used (1) as a flux in the production of metallurgical slags, (2) as a source of hydrofluoric acid by reaction with concentrated sulfuric acid.

Formate: Calcium formate ($Ca(CHO_2)_2$), white solid, solubility: at 0° C. 13.90 grams, at 40° C. 14.56 grams, at 80° C. 15.22 grams of anhydrous salt per 100 grams saturated solution, formed by reaction of calcium carbonate or hydroxide plus **formic acid,** and then evaporation. Calcium formate, when heated with a calcium salt of a carboxylic acid higher in the series, yields an aldehyde.

Furoate: Calcium furoate ($Ca(C_4H_3O \cdot COO)_2$), formed by reaction of calcium carbonate or hydroxide plus furoic acid. Used for preparing fungicides and bactericides.

Hydride: Calcium hydride (CaH_2), white solid, reacts with water yielding **hydrogen** gas and calcium hydroxide; when electrolyzed in fused potassium lithium chloride, hydrogen behaves like chloride and is liberated at the anode. Used as an easily regulated reducing agent in organic chemistry.

Hydroxide: Calcium hydroxide, hydrated lime, slaked lime, milk of lime, lime water ($Ca(OH)_2$), white solid, soluble slightly (about 0.2 gram per 100 milliliters of water), formed (1) by reaction of calcium oxide and water, with the accompanying evolution of much heat, (2) by precipitation of soluble calcium salt solution and **sodium** hydroxide solution. Used (1) as an important and cheap alkali, and so used in many chemical reactions to form calcium salts or to liberate **ammonia** gas from **ammonium** salts, (2) in lime, mortar, and cements, frequently mixed with sand.

Hypochlorite: Calcium hypochlorite, "H.T.H." (High Test Hypochlorite) ($CaOCl_2$) white solid, emits a marked odor in air, contains 60%–65% "available chlorine" and sufficient calcium hydroxide to stabilize, formed by reaction of calcium hydroxide and **chlorine** and evaporating at low temperature. Used as **bleaching** agent for fabrics, as a disinfectant, for the preparation of dilute solution of sodium hypochlorite in laundering, and in the treatment of wounds; "chloride of lime," "bleaching powder" ($CaOCl_2$), white solid, contains 36%–38% "available chlorine." Used as above.

Hypophosphite: Calcium hypophosphite ($Ca(H_2PO_2)_2$), white solid, formed (1) by boiling calcium hydroxide suspension in water and yellow **phosphorus** (phosphine gas, poisonous, evolved), and then evaporation, (2) by reaction of calcium carbonate or hydroxide plus **hypophosphorous** acid, and then evaporation. Used in medicine.

Iodide: Calcium iodide (CaI_2), yellowish-white solid, soluble, formed by reaction of calcium carbonate or hydroxide plus **hydriodic acid,** and then evaporation. Used in photography.

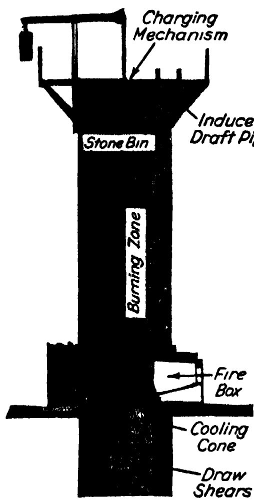
Lactate: Calcium lactate ($Ca(C_3H_5O_3)_2 \cdot 5H_2O$), white solid, solubility: at 0° C. 3.1 grams, at 30° C. 7.9 grams of anhydrous salt per 100 grams water, formed by reac-

tion of calcium carbonate or hydroxide plus **lactic acid,** and then evaporation. Used in medicine.

Malate: Calcium malate ($CaC_4H_4O_5 \cdot 2H_2O$), white solid, solubility: at 0° C. 0.670 gram, at 37.5° C. 1.011 grams of anhydrous salt per 100 grams saturated solution. Formed (1) by reaction of calcium carbonate or hydroxide plus **malic acid,** (2) by precipitation of soluble calcium salt solution and sodium malate solution.

Nitrate: Calcium nitrate, "Norway salpeter" ($Ca(NO_3)_2 \cdot 4H_2O$), white solid, soluble, formed by reaction of calcium carbonate or hydroxide plus **nitric acid,** and then evaporation. Used widely as a nitrogenous fertilizer (initially manufactured in Norway by neutralizing the dilute nitric acid produced in the fixation of atmospheric **nitrogen** by the electric arc process). Also used in pyrotechnics and as a source of nitrate for other nitrates.

Oxalate: Calcium oxalate (CaC_2O_4), white precipitate, insoluble in weak, soluble in strong, acids, formed by reaction of soluble calcium salt solution and **ammonium** oxalate solution. Solubility at 18° C. 0.0056 gram anhydrous salt per liter of saturated solution.



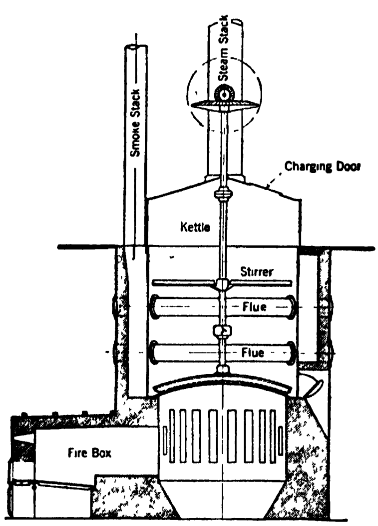
Lime kiln.

Oxides: Calcium oxide, lime, burnt lime, quick lime, live lime, caustic lime (CaO), white solid, melting point 2570° C; reacts with water to form calcium hydroxide with the evolution of much heat; reacts with water vapor and carbon dioxide of the atmosphere to form calcium hydroxide and carbonate mixture (air slaked lime); formed by heating limestone to a high temperature (800° C.) and removal of carbon dioxide also formed. An important and cheap alkali, which is used (1) as calcium hydroxide with water, (2) as calcium carbonate for high temperature reactions (carbon dioxide evolved as gas); calcium peroxide (CaO_2), white solid, only slightly soluble in, but reacts slowly with, water, formed by reaction of soluble calcium salt solution and sodium peroxide. Used as a germicide.

Phosphates: Tricalcium phosphate, tertiary phosphate of lime, phosphorite, bone ash ($Ca_3(PO_4)_2$), white solid, the source of practically all phosphate and phosphorus-containing substances; insoluble in water; reactive with **silicon** oxide and carbon at electric furnace temperature yielding **phosphorus** vapor (later condensed under water) plus carbon monoxide plus calcium silicate molten slag; reactive with sulfuric acid to form, according to the proportions used, the two following calcium phosphates or **phosphoric acid,** dicalcium hydrogen phosphate, secondary phosphate of lime, reverted phosphate ($CaHPO_4$), white solid, insoluble, used as a source of acid in **baking powders** for leavening; calcium dihydrogen phosphate, primary phosphate of lime, superphosphate ($Ca(H_2PO_4)_2 \cdot H_2O$), white solid, soluble, formed (1) by reaction of tricalcium phosphate and sulfuric acid, yielding calcium dihydrogen phosphate plus calcium sulfate, the mixture constituting the widely produced and utilized "superphosphate" **fertilizer,** (2) by reaction of tricalcium phosphate and sulfuric acid yielding phosphoric acid plus calcium sulfate, and, after separation, the resulting phosphoric acid is treated with tricalcium phosphate yielding calcium dihydrogen phosphate, known as "treble superphosphate"; used also as a source of acid in baking powders for leavening.

Silicates: Calcium silicates, four in number, have been prepared by high temperature methods, and identified, $3CaO \cdot SiO_2$, prepared by heating the constituents to a temperature below the melting point (melting point is 1700° C. but substance unstable); $2CaO \cdot SiO_2$, melting point 2080° C., but upon slow cooling changes to forms of different volume; $3CaO \cdot 2SiO_2$, melting point 1475° C.; $CaO \cdot SiO_2$, wollastinite, melting point approximately 1400° C. These silicates are important in connection with Portland cement.

Sulfate: Calcium sulfate, **gypsum** ($CaSO_4 \cdot 2H_2O$), plaster of Paris ($CaSO_4 \cdot \frac{1}{2}H_2O$), **anhydrite** ($CaSO_4$), white solid, soluble slightly (about 0.2 gram per 100 milliliters of water), formed by reaction of soluble calcium salt solution and sodium sulfate solution. Used (1) in plaster, stucco and cement, frequently mixed with fillers.



Calcining kettle for the production of plaster of Paris from gypsum.

Dry plaster is gypsum which has been heated until about one-fourth of the original water remains. This dry plaster, when mixed with water, can be worked or shaped but soon sets to a coherent and adherent solid, which is composed of interlacing crystals of gypsum, (2) as a filler for **paper** and **paints.**

Sulfides: Calcium sulfide (CaS), grayish-white **solid,** reactive with water, formed by reaction of calcium sulfate and **carbon** at high temperatures. Used as a depilatory, and in luminous paints; calcium hydrogen sulfide, calcium bisulfide ($Ca(HS)_2$), formed in solution by saturating calcium hydroxide suspension with hydrogen sulfide. Used as a depilatory.

Sulfites: Calcium sulfite ($CaSO_3$), white precipitate, formed by reaction of soluble calcium salt solution and **sodium** sulfite solution, or by boiling calcium hydrogen sulfite solution; calcium hydrogen sulfite, calcium bisulfite, sulfite liquor ($Ca(HSO_3)_2$), formed in solution by saturating calcium hydroxide or carbonate suspension with **sulfurous acid.** Used as cooking liquor (with excess sulfurous acid) in converting wood chips into paper pulp.

Tartrate: Calcium tartrate ($CaC_4H_4O_6 \cdot H_2O$), white solid, solubility: at 0° C. 0.0875, at 80° C. 0.180 gram

anhydrous salt in 100 milliliters saturated solution, formed (1) by reaction of calcium carbonate or hydroxide and **tartaric acid**, (2) by precipitation of soluble calcium salt solution and **sodium** tartrate solution. (R.K.S.)

CALCULATOR, NETWORK. The network calculator is an elaborate layout of **inductance, capacitance,** and **resistance** units, and **generators** used for duplicating the electrical characteristics of a power system so various system conditions may be studied. These components are connected to panels where, by means of switches or plug connections, a network of them may be wired up relatively easily. This network is given the same electrical characteristics as the system to be analyzed, that is, the lumped values of the calculator are set for the values equivalent to the actual system values. Then by connecting electrical **instruments** in the network the electrical quantities in any part of the network may be measured. These measurements give the results which would be obtained in the real transmission system if a similar operation had been performed on it. Thus by duplicating system conditions in the laboratory with the calculator and measuring the electrical results of various operations the solutions to many involved problems in transmission work may be found without laborious mathematical calculations. These calculators are set up in the laboratories of only a few large companies and operating engineers send in their problems for solution. (L.R.Q.)

CALCULUS, DIFFERENTIAL AND INTEGRAL. The differential and integral calculus is a branch of mathematics dealing with the rate of change of a function and with the inverse process.

Sir Isaac **Newton** (1642–1727), the famous English scientist and mathematician, and Gottfried Wilhelm Leibnitz (1646–1716), a famous German philosopher and mathematician, are considered the founders of the calculus.

Some indication of the subject matter usually included under the term calculus may be found by consulting the following topics: **Variable, Constant, Functions, Continuous Functions, Limits, Derivative of a Function of One Variable, Differentials, Differentiation Technique, Higher Derivatives, Tangents and Normals to Plane Curves, Maxima and Minima, Partial Derivatives, Infinite Series, Expansion of Functions in Series, Indeterminate Forms, Concavity and Convexity of a Plane Curve, Curvature of a Plane Curve, Indefinite Integrals, Integration Technique, Definite Integrals, Area under a Plane Curve, Length of Plane Curve Arc, Double Integral, Triple Integral, Volumes by Double Integrals, and by Triple Integrals, Line Integrals, Differential Equations.** (L.L.S.)

CALCULUS OF FINITE DIFFERENCES. The calculus of finite differences is a study of methods of treating problems involving differences of functions.

If we have given a sequence $u_0, u_1, u_2, \cdots, u_n, \cdots$, and if we form the differences of consecutive terms of this sequence, as u_1-u_0, u_2-u_1, $\cdots$, we call these differences the first differences of the original sequence and denote them by $\Delta u_0, \Delta u_1, \Delta u_2, \cdots, \Delta u_n, \cdots$, so that $\Delta u_n = u_{n+1} - u_n$. We may then form the first differences of these first differences and obtain second differences, denoted by $\Delta^2 u$, so that $\Delta^2 u_n = \Delta(\Delta u_n) = u_{n+2} - 2u_{n+1} + u_n$; and similarly we may form third and higher differences.

The study of the properties of successive differences is applied to problems in **interpolation** and quadratures (**approximate integration**), to problems in the summation of series, and also to the solution of **difference equations.** (L.L.S.)

CALCULUS OF VARIATIONS. The calculus of variations is concerned with the problem of maxima and minima of functions of functions. In the ordinary differential calculus, the problem of extreme values of functions is dealt with, in which a function of one or more independent variables is examined to determine the values of the variable or variables for which the function takes maximum or minimum values. The calculus of variations is a natural extension of this problem. In the calculus of variations, a curve or surface (or corresponding function) plays the role of the independent variable of the former problem.

The function to be minimized or maximized in the calculus of variations is essentially of the form

$$\int_a^b f(x,y,y')dx,$$

where y is a function of x and $y' = dy/dx$, or some generalization of this. The central problem of the calculus of variations is then to find the function $y = F(x)$ or the corresponding curve which will make the above integral take a minimum value or a maximum value.

A few of the simplest problems of the calculus of variations are (1) to find the shortest distance between two given points, (2) to find the path along which a particle will move under the action of gravity from one given point to a lower given point in the shortest time, (3) to find the minimum surface of revolution.

The calculus of variations is applied to many important problems of geometry, and also has many valuable applications to physics, as in Hamilton's principle and the principle of least action.

Problems in the calculus of variations may be solved either directly, by approximation, as in Ritz's method, or indirectly, by reduction to **differential equations.** (L.L.S.)

CALDERA. Derived from a Spanish word meaning caldron, the term caldera has been given to great craterlike depressions which are either the result of subsidence of lava within the body of a **volcano** or of an explosive eruption of terrific violence. Examples of these craters of explosion or subsidence are Crater Lake, Oregon, Mt. Tamboro, in the Dutch East Indies, and the original *La Caldera* in the Canary Islands. Crater Lake, which occupies the caldera, is 2000′ deep and about 25 sq. mi. in area, surrounded by cliffs whose maximum height is 2000′ above the lake. (E.S.C.S.)

CALEDONIAN DISTURBANCE. Silurian.

CALENDAR. The problem of time-keeping has always been a vexing one to mankind. There are three "natural" units, the solar **day**, the lunar **month**, and the tropical **year**. The normal or true solar day had to be abandoned with the improvement of mechanical timekeeping devices and the mean solar day has been adopted as the standard short unit for keeping records. The task of the calendar builder is to combine this unit with the two longer units and, since the three are mutually incommensurable, a rigorous solution of the problem is impossible and compromises must be made.

The fact that the economic world is largely dependent upon agriculture introduces one important restriction on the freedom of the calendar builder. The seasons should remain at approximately the same place in the completed calendar from year to year. The date upon which the sun apparently passes through the **vernal equinox** is of fundamental importance to the agriculturalist and for many centuries was considered as the time of starting a new year. One of the earliest calendars on record started the year on this date and then proceeded through ten lunar months. Such a calendar would cover only 295.3 mean solar days, while the period from one passage of the sun through the vernal equinox to the next is 365.2422 days. The period between the end of one year to the beginning of the next was determined by

the priesthood and politicians with hopeless confusion resulting.

The first step toward the modern calendar was made by Julius Caesar with the advice of the astronomer Sosigenes. The so-called Julian Calendar discards the lunar month and adopts 365.25 days as the length of the year. This year is divided into twelve periods (months) of 30 or 31 days. The normal year was 365 days in length but, to make up the extra ¼ day, an extra day was intercalated (i.e., put into the normal calendar) every four years.

Running parallel with the Julian Calendar we find the far more ancient calendar of the Jewish and Mohammedan peoples, which holds rigorously to the lunar month. Division of the number of days in the tropical year by the days in the lunar month will indicate that there are 12.36 lunar months in a tropical year. To retain the synchronism between the calendar and the seasons, this calendar is variable in the number of months which it contains and the process of intercalating months becomes very complicated. However, the Eastern calendar exerts a powerful effect upon the calendar of the Western world, because of the fact that the date of Easter is fixed by a date on the Eastern calendar.

In A.D. 325 the Christian Church took its first step in calendar building and at the Council of Nice made two decrees: a decree that the sun should pass through the vernal equinox on the 21st of March on the Julian Calendar, and a second decree relative to the date for the celebration of Easter. The latter of the two decrees was within the province of the Church and can be followed; the former, however, applies to factors beyond the control of man.

It should be noted that the length of the tropical year is 0.0078 day less than the 365.25 days of the Julian Calendar. This means that after the lapse of 1000 years the sun will pass through the vernal equinox 7.8 days earlier than the 21st of March, assuming it was at the vernal equinox on this date in the first place. By 1582 the date of the vernal equinox was the 11th of March instead of the 21st and Pope Gregory decided to return the sun to its proper date and to modify the calendar in such a way that the error would not reappear. The Gregorian Calendar is identical with the Julian except in the fact that only such century years are leap years as are divisible by 400. This is equivalent to dropping 3 days every 400 years leaving an average length for the year of 365.2425 days which differs from the tropical year by only 0.0003 day. This calendar was immediately adopted by all Catholic countries but the Greek Church and most Protestant countries refused to recognize it. The confusion following this change persisted well down into the present century (Rumania used the Julian Calendar until 1919) and is still felt by historians in reading records of the early years of this country when both calendars were in use.

Within the past 20 years a strong movement has been on foot to modify the calendar in the attempt to have dates and days of the week agree in successive years. Any such scheme involves the necessity of introducing one day each year without date or day of the week, and two such days on leap years, if the year and the seasons are to retain the present synchronism. This intercalation of a day will break the 6-day sequence between Sabbaths, an idea which is abhorrent to many religious sects. The scheme which has the most general support is one in which the year is divided into four equal quarters of 3 months each. In each quarter the first month has 31 days and the second and third, 30 each. This gives exactly 13 weeks in each quarter, and 52 weeks in each year. The days are to be intercalated without date or day of the week between December 30 and January 1 each year and between June 30 and July 1 every leap year (e.g., the normal calendar would read Saturday, Dec. 30; New Year's Day; Sunday, Jan. 1). (W.K.G.)

CALF. 1. The young of cattle and of related wild species. 2. The fleshy mass formed by the muscles at the back of the leg below the knee. (A.W.L.)

CALICHE. An important natural fertilizer occurring in Chile as a deposit containing **sodium** nitrate and other soluble salts. These deposits were of great economic importance, prior to the development of present-day methods for the fixation of atmospheric **nitrogen.** Geologists more commonly apply the term to a calcareous deposit which in semi-arid regions accumulates at and near the surface of the ground through evaporation of capillary water. (R.M F.)

CALIPASH. A structure beneath the carapace of **turtles** containing a greenish fat, sometimes regarded as a delicacy. (A.W.L.)

CALIPEE. A structure lying neor the plastron of the **turtles,** similar to the calipash. (A.W.L.)

CALIPERS. **Measurement.**

CALKING. **Forging.**

CALL INDICATOR. Continuity and speed of service are among the primary objectives of the telephone companies. This would be fairly simple if all the phones on a system were manual or all automatic (see **Telephony**), but where a given exchange area involves both types of service the problem is more involved. In order to avoid the necessity of a dial subscriber having to call the operator and give her the desired number, the call indicator has been developed to give the manual operator the number automatically as it is dialed. Thus when a subscriber on an automatic office calls one on a manual office, he may simply dial the desired number. The call indicator circuit then causes the dialed number to appear on a board before the operator who reads the called number and completes the connection. In this way, it is not necessary for the subscriber to make any distinction between calls to other automatic subscribers or manual subscribers. (L.R.Q.)

CALLA LILIES. **Aroids.**

CALLIER QUOTIENT. The ratio of the density measured by diffused light to the density measured by specular (direct) light. (C.B.N.)

CALLUS. There are five common meanings with which this term is used throughout biological science.

1. Callus is a thickened horny mass found in the outer layer of the skin, which is the result of continued pressure or friction.

2. Callus designates a thickened spot near the **umbilicus** in the shells of certain snails.

3. Callus also denotes a tissue formed about the fragments of a broken bone. This tissue eventually develops into bone, and by this means the fracture heals.

4. Callus is a term applied to colorless glistening pads of substance which close the sieve plates of **sieve tubes** which have ceased to function. The formation of these callus pads usually ends the activity of the cell, although they may be dissolved later and activity resumed.

5. Callus designates a certain protective tissue which occurs widely in plants. When the root or stem of a **gymnospermous** or a **dicotyledonous** plant is wounded, exposing the tissues within, the cambium cells around the wound begin to divide rapidly, forming a protective mass of soft parenchymatous tissue. These living cells are called callus, or wound tissue, and in time will entirely close the wound if the latter is not too extensive. Callus tissue may even grow over such a wound as results when a tree is girdled, that is, when a ring of bark is removed completely round the stem. Ordinarily,

however, such a wound is fatal. After the tissue is formed, cell differentiation goes on and a new **phellogen** layer may be formed, as well as the other tissues composing the cortex of the **stem**. The **cambium** becomes once more a continuous layer. When wounds are made in pruning, that is, when a branch is cut off, callus tissues gradually form a ring which spreads over and finally completely closes the wound. (A.W.L., R.S.M., R.M.W.)

CALM. The absence of horizontal air motion is recognized as a calm. (P.E.K.)

CALOMEL. **Mercury.**

CALORESCENCE. This term refers to the production of visible light by means of energy derived from invisible **radiation** of frequencies below the visible range. Tyndall found it possible to raise a piece of blackened platinum foil to a red heat by focusing upon it infra-red radiation from an arc or from the sun, the visible wavelengths having been filtered out. It is to be noted that the transformation is indirect, the light being produced by heat and not by any direct stepping up of the infra-red frequency. A somewhat analogous phenomenon is the production of visible sparks or the glowing of a fine platinum wire in a resonant circuit energized by long-wave Hertzian radiation. (L.D.W.)

CALORIE. The gram calorie is the quantity of heat required to raise the temperature of one gram of pure water from 15 to 16° C. Since the specific heat of water is not quite constant, it is necessary to specify the degree interval used in defining the calorie, this one being chosen because water has its average specific heat at this point. The calorie is equal to about $\frac{1}{252}$ B.T.U., and is dynamically equivalent to about 41,855,000 ergs of energy. The heat unit thus defined is the one most commonly employed in physics. For some purposes it is convenient to use a larger unit, the kilogram calorie, which is equal to 1000 gram calories. The calorific values of foods are, for example, usually expressed in terms of this unit. (L.D.W.)

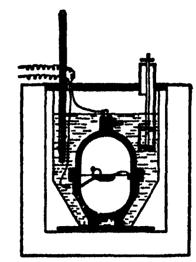
CALORIFIC VALUE. **Heating Value.**

CALORIMETRY. The measurement of quantity of heat; any apparatus used for the purpose being called a "calorimeter." The most obvious result of the application of heat is the rise in temperature of the body to which it is applied; hence it is natural that this readily measurable effect should be utilized in heat measurement. Since the application of heat melts solids and vaporizes liquids, these effects also furnish the basis of valuable calorimetric methods.

The common units of heat are based upon the temperature-raising effect. Thus we have the gram **calorie**, the kilogram **calorie**, and the British thermal unit. The latter, equal to about 252 gram calories, is the quantity of heat required to raise the temperature of one pound of water one Fahrenheit degree. Gas companies sometimes use a large unit called the "therm," viz., 100,000 B.T.U., but this name has also been applied to various multiples of the calorie and is hence ambiguous.

The so-called water calorimeter is essentially a thermally insulated metal cup containing water and furnished with a thermometer. The quantity of heat to be measured is applied to the water, and the rise of temperature resulting, multiplied by the mass of the water, gives the number of heat units received. Corrections must of course be made for the heat absorbed by the cup, thermometer, and other accessories, the "water equivalent" of which is in the computation simply added to the mass of actual water. Allowance must also be made for heat lost or unintentionally introduced through radiation and conduction; for which purpose **Newton's law of cooling** is commonly used.

Since the **heat of fusion** of ice is known to be very nearly 79.71 calories per gram, the heat to be measured may be applied to the melting of ice without change of temperature, and the mass of ice melted, multiplied by the heat of fusion, gives the quantity of heat. Bunsen, Lavoisier and Laplace, Black, and others devised calorimeters based upon this principle.



Bomb calorimeter for determining the heating value of solid and liquid fuels.

A steam calorimeter was perfected by J. Joly (1886) and used for the accurate determination of specific heats of solids, liquids, and gases. In principle this apparatus consists of a balance, with the specimen hung from one pan and surrounded by an enclosure which can be flooded with steam. The mass of moisture condensing on the specimen, multiplied by the heat of vaporization of water, gives the quantity of heat imparted to the specimen.

Other calorimetric methods have been proposed and tested, and many special calorimeters have been designed for measuring heats of combustion of fuels, food values, heats of chemical reaction, heat from electric currents, etc.; most of these methods depend upon one or another of the principles mentioned above. (L.D.W.)

CALORIZING. Production of a protective coating of iron-aluminum alloy on iron or steel. The articles are ordinarily coated by heating to a high temperature in a closed container packed with powdered aluminum. Other processes include impregnation at high temperature with an aluminum chloride vapor and spraying with molten aluminum from a spray gun and then heating to a high temperature. When the aluminum coating is held at high temperatures, an iron-aluminum alloy forms which is resistant to oxidation and corrosion by hot combustion gases, especially those containing sulfur compounds which are particularly corrosive to bare iron or steel.

Steel sheets are aluminized by a hot-dip process similar to galvanizing. The principal applications for such a product are furnaces and ovens, automobile mufflers, and other equipment requiring heat and corrosion resistance. When a sheet which has been coated with aluminum by a hot-dip process is exposed to a temperature over 1000° F., the aluminum forms an iron-aluminum alloy which is heat- and corrosion-resistant. (R.H.H.)

CALYX. For the use of this term in botany, see **Flower.** In zoology, a calyx is a cup-shaped or funnel-like structure, such as the body of a **sea-lily** and the chambers branching from the principal cavity of the vertebrate **kidney.** (A.W.L.)

CAM. A cam is a rotating or sliding member which imparts a desired motion or series of motions to another member. Cams are used whenever a desired motion is of such character that it cannot be obtained by using cranks or linkages. There are two important forms of cams: radial cams where the follower moves in a plane perpendicular to the axis of the shaft, and cylindrical cams where the follower moves in a plane parallel to the axis of the shaft. Each of these types may be classified further as positive-motion cams in which the reciprocating motion of the follower is definitely controlled by the cam, and nonpositive-motion cams in which the follower is returned to its starting point by spring or gravity action.

Fig. 1 shows a radial cam with a flat follower or cam tappet. The cam is integral with the cam shaft. The cam profile is composed of two circular arcs connected

by tangent lines. Cylindrical, helicoidal, and plane surfaces are used for cam faces whenever possible, since they are more easily and accurately manufactured than irregular curves.

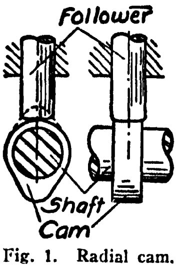


Fig. 1. Radial cam.

The radial disk cam, at the right of Fig. 2, is similar to the cam of Fig. 1. Roller followers are preferred to flat followers because the line contact between the roller and the cam is of a rolling nature, since the sliding is transferred to the pin that carries the roller. The face cam, at the left of Fig. 2, is a positive-motion cam, but is much more difficult to manufacture than a disk cam because the cam groove must be of accurate uniform width. This face cam has a cast iron disk on which the inner and outer hardened steel plates are screwed and dowelled.

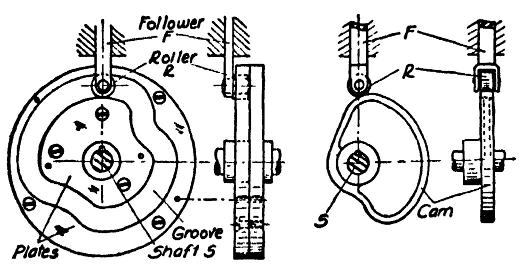

Fig. 2. *Left:* Positive-motion cam. *Right:* Radial disk cam.

Fig. 3 shows a solid cylindrical cam with a bell-crank or lever follower for the thread-controlling function on moderate-speed sewing machines A development or

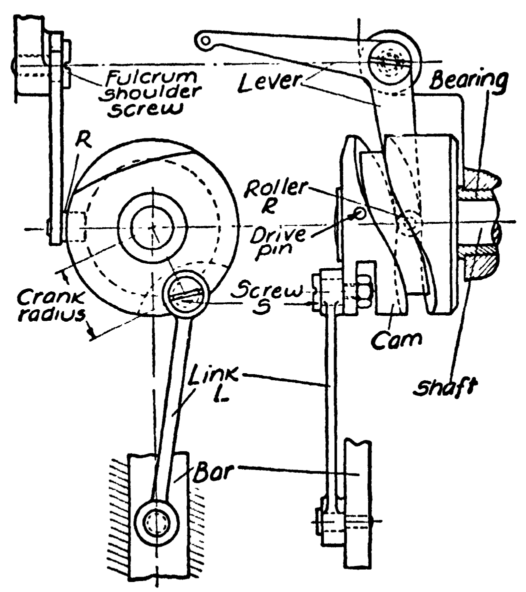

Fig. 3. Solid cylindrical cam.

layout of a portion of a cylindrical cam is shown in Fig. 4. This development shows uniform or straight-line motion of the roller, modified by an arc equal to the roller radius at the beginning and end of each phase of motion, to permit gradual acceleration and to provide roller clearance. The drum cam may have positive motion and will therefore require a cam strap on either side of the roller, or it may be constructed with a single strap, in instances where the inertia of the slide is great enough to enable the roller to remain at rest unless acted on by the cam strap. (H.C.H.)

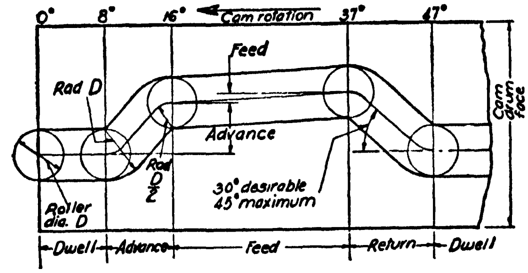

Fig. 4. Development of portion of cylindrical cam.

CAMBER. Camber is the upward curvature which is given to **bridge** trusses with theoretically horizontal lower **chords**, bridge girders with theoretically horizontal bottom **flanges** and **beam bridges** to compensate for the actual **deflection.** Although these deflections are small in a properly designed structure, they may be objectionable from the standpoint of appearance. Due to an optical illusion these structures appear to have a pronounced downward deflection. This term is also used to denote the initial curvature which occurs in steel beams as the result of rolling.

In short-span trusses camber is obtained by lengthening the top chords $\frac{1}{8}$ to $\frac{3}{16}$" for each 10' of length. No change is made in the lower chords and **verticals** but the length of the **diagonals** must correspond to the new outline. Long-**span** trusses are cambered by increasing the geometrical length of the **compression members** and decreasing the geometrical length of **tension members.** The change in length is based on the calculated longitudinal **deformation** of the members under **dead load** and partial or full **live load.**

It is not customary to camber short-span girders. Long-span girders are cambered by fabricating them with an upward curvative corresponding to a predetermined amount of deflection. This is accomplished by using two or more plates for the **web,** spliced in such a way as to produce this curvature approximately. The straight flange angles and cover plates are then bent to the desired curvature during the fitting-up operation.

Camber may be obtained in a beam bridge by placing the beams so that the initial curvature due to rolling is upward. The initial curvature may be increased by heating the flange on the concave side with a torch. (C.W.C.)

CAMBIUM. In **Gymnosperms** and **dicotyledonous Angiosperms,** a large part of the tissues of the stem is derived from a special layer of cells known as the cambium. The cambium originates from certain cells of the procambial strand. In the procambial strand of the stem (that part of the growing tip in which **cell** differentiation first takes place), cell differentiation commences at the tangential edges of the strand and progresses towards the center, forming primary xylem cells towards the center of the stem and primary **phloem** cells towards the surface Some of the cells in the middle portion of the procambial strand do not differentiate into **xylem** or phloem, but become meristematic cells, dividing actively. These are the cambium cells. Often they begin to divide before the other cells of the procambial strand have ceased elongating.

At first the cambium is a vaguely defined layer of cells occupying the middle portion of the procambial strand. In **roots** the cambium appears on the inside of the primary phloem strands, which alternate with the primary xylem strands.

Gradually additional cells are formed laterally, either from those cambium cells already formed or by differentiation of parenchyma cells of the medullary ray, until a complete cylinder of cambium exists. Once formed, the cambium of woody plants persists throughout the life of the plant; in herbaceous plants its existence is

rather brief, all cells of the stem becoming mature early in its development.

There are two types of cells present in the cambium of any plant. The cells of one type are isodiametric, that is, all dimensions are more or less equal; these cells give rise to the cells of the vascular rays. The other cambium cells are long cells with tapering ends; the cells which result from the division of these become either tracheids, vessels, fibers, or sieve tubes. The elongate cambium cells vary in dimensions in different plants. In various Gymnosperms they may be 3000–4000 microns or more in length; in dicotyledons they are much shorter, varying from 100–800 microns. In width cambium cells vary in different plants from 20–40 microns, and in thickness, or radial dimension, 5–15 microns. Cambium cells have a dense **cytoplasm** in which **vacuoles** are either lacking or very minute. Each cell of the cambium has a single **nucleus** which is usually elongated. The walls, especially the tangential ones, are very thin. Division of the cambium cells occurs in a longitudinal tangential plane, that is, the cell divides lengthwise to form two slender elongate cells, one of which lies outside the other, towards the outside of the stem or root. It is certain that the division is always mitotic (**mitosis**). One of the cells resulting from this division soon begins to change its form. If this differentiating cell is on the inside of the cambium cylinder it may elongate even more, its ends sliding by and between those of other cells about it. Presently thickening of the wall occurs through deposits of cellulose which are laid down on the primary wall. The cytoplasm of the cell gradually disappears. When mature, this cell, now a **tracheid**, is a long slender tapering cell with thick wall and no protoplasm. In the wall are numerous **simple** or **bordered pits**, which are continuous with pits of adjoining cells. In Gymnosperms, all elongate cells derived from the cambium become tracheids, except in those forms which have wood parenchyma cells. In these, transverse divisions occur to form a linear row of short cells. In angiosperms, other types of cells are formed. One of these, the fiber, differs little from the tracheid except that it has a thicker wall, in which there are few small pits. The other type is quite distinct. The cambium derivative which is going to form one of these does not elongate noticeably, but does increase greatly in diameter. As it increases, a large central vacuole forms, and the nucleus moves to a position near the middle of the end wall. At that stage, the vessel appears as a series of very large vacuolate cells separated from one another by distinct end walls. When full size is reached, secondary wall thickening occurs. Then the end wall breaks down, leaving a series of cells forming a long open tube; in many plants perforations are formed in the end wall, so that direct continuity from cell to cell exists. The tremendous increase in diameter of the vessel cells causes the cells around it to be flattened and crowded into angular shapes and irregular arrangements. Once the walls have formed and the cell matured, no further change takes place. Its structure is fixed permanently.

The cells which are formed externally to the cambium become phloem cells. The manner of differentiation is not so well known in these cells as in the xylem cells. Apparently divisions of these phloem mother cells, cut off from the cambium cells, are much more frequent than are divisions of the xylem mother cells. Phloem parenchyma results from the transverse division of one of these cells to form a longitudinal series. In angiosperms each phloem mother cell divides unequally, cutting off a very small cell from the corner of the mother cell. The larger cell forms part of a sieve tube, the smaller becomes a companion cell. Often the companion cell divides again to form two or more companion cells associated with a single sieve tube. The cytoplasm of the companion cells remains dense, develops few vacuoles, and always has a well-developed nucleus. In the sieve tube, on the contrary, the cytoplasm becomes peripheral, and there is a large central vacuole. The nucleus has disappeared in the mature sieve tube. The end walls of the sieve tube cells are characterized by the presence of porous places called sieve plates. The pores of these sieve plates result from the enlargement or fusion of the protoplasmic strands, known as plasmodesma strands, which connect the protoplasts of adjoining cells. The enlargement of these strands causes an enlargement of the pores through which they pass, so that conspicuous connections are formed between adjacent cells. The development of sieve tubes in Gymnosperms is very similar to that in angiosperms, but no companion cells are formed, and the pores in the sieve plates are much smaller. The development of phloem fibers is like that of xylem fibers.

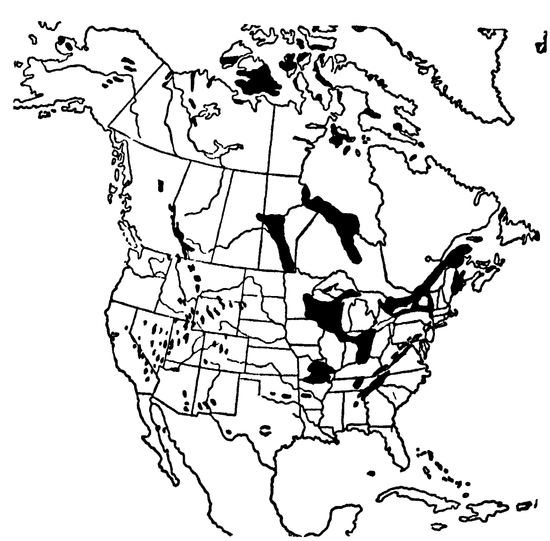
It is obvious that with continued formation of xylem cells inside the cambium and consequent increase in stem diameter, the cambium is constantly being pushed outward and stretched. Gliding growth of cambium cells and those cut off from them causes increase in circumference of the cambium cylinder and so prevents any breaking of the same. For a time the phloem cells maintain their shape against the pressure of the enlarging stem within. In time, however, the older phloem cells become crushed and distorted beyond recognition.

The isodiametric cambium cells divide to form either xylem or wood ray cells inside, or phloem ray cells outside the cambium. These cells differentiate directly into ray cells.

All tissues derived from the divisions of the cambium cells are known as secondary tissues, in contrast to the primary tissues, which are formed by differentiation of the cells of the procambial strands.

Another cambium, the cork cambium (formerly called phellogen), arises in the pericycle of roots and in the outer cortex of stems. It produces cork and secondary cortex. (See **Bark.**) (R.M.W., B.S.M.)

CAMBRIAN PERIOD. The earliest subdivision of the **Paleozoic Era.** Type locality, North Wales. The formations of this system were first studied and named by Adam Sedgwick in 1835. The Cambrian period began some 500 million years ago, and lasted for 70–80



Map showing known areas of outcrops (surface distribution) of Cambrian, Ordovician, and Silurian strata in North America.

million years. Cambrian formations are well exposed in North America in the Appalachians and Rocky Mountains. Important lower Cambrian beds containing the oldest known faunas occur in British Columbia. Other countries in which the Cambrian is well exposed are Sweden, Britain, Spain, Scandinavia, France, Germany,

eastern China, northeastern Siberia, India (Himalayas and Salt Range), Morocco, Australia, Argentina and Antarctica. Cambrian sediments represent the earliest evidence of deposition in well defined **geosynclines**, the principal types being **sandstones, shales** and **limestones. Tillites** indicate continental glaciation. The maximum thickness of 40,000′ of Cambrian strata occurs in North America. The oldest known invertebrate fossils occur in this period, the principal types being **trilobites, chitinous brachiopods,** and primitive **graptolites;** all of which had a marine habitat. It is interesting to note that the paleontological record begins with such highly developed organisms as trilobites, whose ancestors are entirely unknown in the pre-Cambrian formations. The "father" of American Cambrian stratigraphy and paleontology is Charles D. Walcott. The base of the Cambrian has not been clearly defined and in some places it probably passes without hiatus into the lower **Proterozoic.** In eastern North America the top of the Cambrian is also under debate, the upper beds forming the base of a new system called the Ozarkian by E. O. Ulrich. (R.M.F.)

CAMEL. Mammalia, Artiodactyla. Animals with long legs and necks and a conspicuously humped back. They are adapted for life in arid regions, including sand deserts, by the broad feet and slit-like nostrils; internally the development of cells for the retention of water in one part of the stomach is especially important for life in such regions.

The two existing species of camels, the Arabian, *Camelus dromedarius,* with one hump and the Bactrian, *C. bactrianus,* with two, are found in the Old World. The Arabian camel is found both in Africa and Asia and the Bactrian in the desert regions of Central Asia. Both species have been domesticated. They are used for riding and as beasts of burden, and also supply foods in the form of milk and flesh. Their hair is used in making fabrics.

The Arabian camel was introduced into the southwestern states by the United States government in 1856 but after many years of apparent success the experiment was abandoned. The animals which were freed died out after persisting for some years.

The group is represented in the New World by the **llama** and related species. (A.W.L.)

CAMEL-CRICKET. Insecta, Orthoptera. Wingless insects related to the **katydids.** They live in dark moist places and are dull colored. These facts together with the strongly humped back give them their name. They are also called cave-crickets. (A.W.L.)

CAMERA, COLOR. Color Camera.

CAMERA, MOTION-PICTURE. Motion-picture cameras may be divided into two classes: (1) those in which the film moves intermittently, being at rest during the actual exposure (intermittent movement) and (2) those in which the film moves continuously (continuous movement). Cameras of the second class are used chiefly for high-speed cinematography and are described under the heading of **high-frequency photography.**

In a motion-picture camera with intermittent movement (see Fig. 1) the film is drawn from the roll at the top and delivered to the take-up reel at the bottom by a sprocket which is driven by a spring motor, or, in professional cameras, by an electric motor. The film passes around the sprocket then through the film gate and finally around the opposite side of the sprocket and thence to the take-up spool. The supply spool (unexposed film) and the take-up spool (exposed film) are driven in the directions shown by the same mechanism as the sprocket. Since the sprocket operates continuously while the claw pull-down produces an intermittent movement of the film in the film gate, it is necessary to leave a loop on either side to prevent damage to the performations of the film.

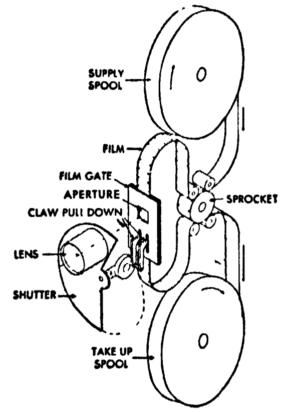


Fig. 1.

A rotating shutter, the shaded part of which is opaque, placed between the lens and the exposing aperture exposes the film. The shutter is synchronized with the pull-down mechanism so that the film is stationary during the exposure—that is, while the lens is uncovered by the shutter—and when the opaque portion of the shutter covers the lens, the perforations of the film are engaged by the claw of the pull-down and the film is moved down into position for the next picture. At an exposure speed of 16 pictures per sec., the actual exposure is from 1/30–1/40 sec. on cameras using 16 mm. film.

In simple cameras designed principally for home movies, the exposure of the film is controlled by the lens diaphragm; cameras intended for professional use, however, are usually provided with shutters in which the open portion may be varied to regulate the exposure (variable shutters). (See **Shutters, Photographic.**)

Film and Film Processing. In America, motion-picture film and motion-picture equipment are available in three sizes: the so-called standard (35 mm.), 16 mm., and 8 mm. In the first-mentioned the pictures are 3/4″ high or 16 to a foot as compared with 40 pictures to the foot of 16 mm. film and 80 to the foot of 8 mm. film. A 100-foot roll of standard 35 mm. film as used in motion-picture theaters requires but 67 secs. to pass through the projector, while a roll of 16 mm. film of the same length requires 4 full minutes, and 8 mm. film 8 minutes. The two smaller sizes—8 and 16 mm.—were originally intended for the making of home movies by the amateur. The use of the smaller size is confined almost entirely to the amateur but the larger (16 mm.) is now widely used in the making of advertising, educational and other films which are not designed to be shown to large audiences.

Most 8 and 16 mm. film is of the reversal type and after exposure in the camera is returned to the manufacturer for processing. The film is processed on continuous machinery consisting of tanks containing the various processing solutions and racks with rollers over which the strand of film is led through the different processing solutions and to the drying cabinets from which it emerges wound on a reel. In reversal processing, the film is developed as a negative first, after which the developed silver of the negative image is removed in a bleaching bath. The film is then cleared of the bleaching solution and the undeveloped silver halide remaining is resensitized and exposed to light to render it developable. To correct for errors in exposure this second exposure is varied in accordance with the amount of undeveloped silver halide remaining, the exposure being controlled automatically by a thermopile which

gives each scene on the film the exposure required to produce a positive image of the proper density and contrast for projection. After this second exposure, the film is again developed, but this time a positive is obtained. After fixing, washing and drying the film is ready for projection. About 1 hour is required for processing.

The reversal process is less expensive since only one film is required and the cost of printing is avoided. Errors in exposure can be corrected almost as well as when negative film is used in the camera and a print on positive film is made for projection. Additional copies can be made if required by printing the positive on a special fine-grain duplicating film which is developed by the reversal process as was the original.

Professional motion picture film (35 mm.) is usually processed by continuous machinery. The strand of film is conducted through one or more developing tanks, a rinsing tank, one or more fixing tanks and several washing tanks. Upon emerging from the washing tanks, it is squeegeed to remove surplus water and conducted into air-conditioned cabinets where it is dried under proper conditions of temperature and humidity. Both negative and positive film are processed the same way but the time of processing is less for positive than for negative film and the speed of the film through the processing machine is usually higher.

Elon-hydroquinone borax developers are generally employed for the development of the negative and development is to a relative low **gamma** while the positive is developed to gammas ranging from 1.9 to 2.4 using a concentrated elon-hydroquinone developer. The general practice is to develop both the negative and the print to predetermined gammas thus placing on the cameraman the responsibility for lighting and exposing so as to obtain the results desired. The processing of both negative and positive film is controlled by developing sensitometric strips at frequent intervals and measuring the densities to determine the exposure-density relationship and the gamma. (See **Sensitometry.**)

Printing. Positive prints for projection are made on motion-picture positive film which corresponds to negative film in size but is coated with a slow, fine-grain, contrast emulsion. Printing is ordinarily by contact but projection printing (optical printing) is used for special effects and for reducing 35 mm. film to 16, or enlarging 16 mm. to the larger size.

In contact printing the developed negative and the positive film are brought together in contact and exposed by moving the two together at a uniform speed, across an illuminated slit.

The exposure of the positive film is controlled by varying the voltage on an incandescent tungsten lamp, by an adjustable diaphragm or back shutter, which controls the amount of light reaching the exposing aperture or by means of what is termed a timing strip or travelling matt. These are made by exposing and developing positive film so as to leave a clear strip down the center or to produce a given density. The width of the clear strip, or the density, is varied according to the amount of light the strip is to transmit. In printing, this timing strip is placed between the light source and the printing aperture so that the light reaching the negative must first pass through this strip. The timing strip moves with the negative—although usually at a lower rate—so that by splicing together timing strips with the proper light transmission and of the proper lengths, the exposure will be changed automatically at the beginning of each scene to compensate for any difference in negative density. (See also **Projectors, Motion Picture.**) (C.B.N.)

CAMERA, PHOTOGRAPHIC. No one knows precisely when it was first discovered that light, admitted to a darkened room through a small aperture, will form an image on the opposite wall of objects beyond the aperture. The first unmistakable reference appears in the *Problemata* of Aristotle. Later, between the 10th and the 15th centuries the discovery was again made and the term *camera obscura* (Latin, dark enclosure or dark room) came into use. Still later, portable models were devised for sketching and through the use of these by Niepce, Talbot and Daguerre, who developed the first practical processes of photography, the word camera became a part of photographic terminology.

All photographic cameras consist of (1) a light-tight enclosure for the sensitive material, (2) a lens, or other means of forming an image, (3) a holder for the sensitive material, and (4) a means of controlling the time during which light is permitted to reach the sensitive material (i.e., a shutter). It may have, in addition to these essentials, (1) a finder to show what will be included in the picture, (2) means for changing the sensitive material, i.e., roll holder, film or plate holder, film cartridge, or film pack, (3) means of focusing the image, e.g., a collapsible bellows, or a tube with a sliding or screw motion, combined with a focusing scale, or focusing screen, (4) a diaphragm to control the amount of light admitted by the lens, (5) a range finder to assist in focusing the image, (6) a depth-of-focus scale, and (7) movements, or swings, which enable the sensitive material to be placed at different angles to the optical axis of the lens.

Cameras, other than those designed for specialized fields of photography, such as photoengraving, photolithography, photomicrography, etc., may be divided into seven classes: (1) box, (2) folding roll film, (3) hand cameras with ground-glass focusing, (4) miniature cameras, (5) reflex cameras, (6) twin-lens cameras, (7) view cameras.

The typical box camera uses roll film; has a single lens with a maximum opening of about f/14; a shutter with one "instantaneous" speed (usually from $\frac{1}{25}$ to $\frac{1}{40}$ second); two reflecting or one direct-vision finder; and may or may not have an adjustable diaphragm. It is designed to meet the needs of those wishing a simple and inexpensive camera.

Considerable ingenuity has been shown by manufacturers in the design of small roll-film cameras and there is considerable variety in this group. The most popular sizes are $2\frac{1}{4} \times 2\frac{1}{4}$, $2\frac{1}{4} \times 3\frac{1}{4}$ and $2\frac{1}{2} \times 4\frac{1}{4}$. Most cameras of this type now have self-erecting fronts, the front springing into position automatically when the camera is opened. Focusing is by scale and is accomplished most often by partially unscrewing the front element of the lens, but in some cameras the lens and shutter may be moved forward or backward as a unit. Inexpensive models are fitted with single lenses and simple shutters; the more expensive with large aperture, high-quality anastigmat lenses and precision shutters. In some cases, the lens is coupled to a range finder to permit direct focusing. Reflecting finders have largely given way in recent years to direct-vision finders. The convenience and compactness of the folding roll-film camera make it one of the most popular types for amateur use.

The term miniature as applied to cameras is rather loosely employed. Here the term miniature will be restricted to cameras utilizing 35 mm. film in cartridges. The typical miniature camera has a metal body and a lens mounted in a metal tube which is extended for focusing by a milled screw. In the less expensive models a between-the-lens shutter is generally used; focal-plane shutters, however, are generally used on the more expensive models to enable lenses to be changed readily. In practically all cases direct-vision finders are employed. Some of these have framing devices so that the field included in the finder will correspond to that of other lenses of different focal length. Many cameras of this type are fitted with coupled range-finders so that the distance of the subject is determined and the lens focused in one operation. In some cases a range-finder is provided—or is available as an attachment—but is not coupled to the lens. In practically all cases the film

spools are carried in light-tight magazines (cartridges) and the film movement is limited by an automatic stop which is responsible for the spacing of the exposures on the roll. On most cameras an interconnecting mechanism prevents the operation of the shutter, after an exposure has been made, until the film has been changed, thus preventing double exposure.

Considerable enterprise has been shown by the promoters of such cameras in providing attachments for specialized work. So much has been done in this direction that some miniature cameras are more nearly universal in their application than any other type of camera.

Hand cameras with ground-glass focusing, using sheet film, glass plates or film-pack are popular with both press and advanced amateur photographers. The most popular of such cameras is fitted with a coupled range-finder and a direct-vision finder and is used much like the miniature camera. Generally ground-glass focusing is resorted to only for copying and other work beyond the capabilities of the range finder. For press photography the camera is usually equipped with a synchronizer for use with flashlamps (see **Flashlamps**).

In the *reflex* camera, a mirror placed at an angle between the lens and the sensitive material reflects the image to a focusing screen at the top of the camera where it is seen right side up and in full size up to the moment of exposure. When the exposure lever is depressed to make a picture, the mirror swings out of the way and covers the focusing screen. It then releases the focal-plane shutter (see **Shutters, Photographic**), exposing the film. The reflex camera is favored by those who wish to study the image on the ground glass but object to the inconvenience of the other types of ground-glass focusing cameras. It is the only camera with ground-glass focusing suitable for moving objects. Ground-glass focusing appeals to many not only because the image is seen full size but the relative sharpness of different planes of the subject (see **Depth of Field**) can be determined. This can only be guessed at when using a range-finder or when focusing by scale.

The *twin-lens* camera is another type of ground-glass focusing camera and has two lenses of the same focal length mounted side by side one of which forms an image on the ground-glass focusing screen while the other, mounted in a shutter, is used in making the picture. The twin-lens camera has many of the advantages of the reflex but is simpler mechanically.

The *view* camera is used chiefly by professional and advanced amateur photographers It is designed for use on a tripod and does not have either a view-finder or a focusing scale. Ordinarily it is made only in sizes 4 x 5″ or larger—5 x 7″ and 8 x 10″ being two of the usual sizes—and has a long bellows extension with vertical and horizontal adjustments to the back, and in some cases to the front, for dealing with difficult subjects such as tall buildings, cramped interiors and industrial products requiring unusual perspective.

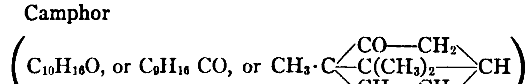
Cameras designed for professional portrait photography are similar to the view camera except that they are much larger and heavier. Ordinarily they are not made in sizes smaller than 8 x 10″ and are fitted with a sliding carriage so that the loaded film holder is placed on one side and the slide withdrawn before the image is focused. When everything is ready, the shutter is closed and the carriage shifted to place the film in position for the exposure. This reduces the time elapsing between focusing and the exposure and assists greatly in making life-like portraits. The camera is mounted on a substantial stand which enables it to be raised or lowered as required. (C.B.N.)

CAMPANULARIAE. Coelenterata, Hydrozoa. An order made up of colonial species with two forms of **polyps**, one nutritive and the other reproductive, known respectively as hydranths and blastostyles, and both enveloped partially in a cupped extension of the sheath of the colony. The common and widely distributed genus *Obelia* is an example. (A.W.L.)

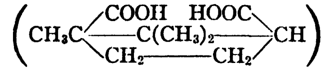
CAMPHOR. *Cinnamomum camphora.* Lauraceae. Camphor is a crystalline compound occurring in various parts, as the wood and leaves, of the camphor tree, a large evergreen tree with light green leaves, growing in many warm regions of southeastern Asia, but particularly on the Island of Formosa. It has been introduced into California, Florida and other warm parts of the United States as an ornamental tree. Its abundance in Formosa formerly gave Japan virtual control of the natural supply of camphor.

The old method of extracting camphor involved chopping down the tree and cutting it up into small chips which were distilled by primitive means. The crude product thus obtained was redistilled to remove the oil of camphor present and the crystalline camphor obtained.

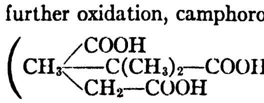
Camphor



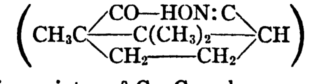
is a white solid, melting point 179° C., boiling point 209° C., of characteristic pleasant odor, insoluble in water, soluble in alcohol or ether. Camphor (1) when heated with **phosphorus** pentoxide, yields cymene ($CH_3 \cdot C_6H_4 \cdot C(CH_3)_2(1,4)$), (2) when heated with **iodine,** yields carvacrol ($CH_3 \cdot C_6H_3(OH) \cdot CH(CH_3)_2(1,2,4)$), (3) when treated with **nitric acid,** yields camphoric acid



and then, by further oxidation, camphoronic acid



(4), when treated with **hydroxylamine,** yields camphoroxime ($C_9H_{16}{:}C{:}NOH$), solid, melting point 120° C., (5) when treated with **nitrous acid** (amyl nitrite plus sodium alcoholate), yields isonitrosocamphor



solid, melting point 153° C. Camphor may be made synthetically by converting pinene into bornyl chloride with hydrogen chloride, thence to isobornyl acetate, thence to isoborneol, and finally oxidizing borneol to camphor.

Camphor is detected by formation of the **oxime** and determination of its melting point. Camphor is used (1) in medicine as a heart stimulant and for other purposes, (2) in celluloid and lacquers, (3) in insecticides and moth preventives. Camphorated oil is a solution of camphor in cotton-seed oil. (See **Aldehydes, Ketones, and Related Compounds.**) (R.K.S., R.M.W.)

CAMPTONITE. A dark **basaltic dike** rock of the essential mineralogical composition of a **diorite,** requiring, however, microscopical examination for proper identification. It was named from the type locality, Campton, New Hampshire. (E.S.C.S.)

CANADA BALSAM. A slightly yellow, transparent, fluid **resin** procured from a North American species of silver fir tree. Used for mounting thin sections of rocks, and of tissues of plants and animals for microscopic examination, between glass slides, and for cementing glass in optical instruments. The **refractive index** of Canada balsam after it has been heated varies between 1.534 and 1.540, according to A. Johannsen. (R.M.F.)

CANADIAN. For the geological significance of this term, see **Ordovician.**

CANAL. In zoology, a canal is a tubular structure or passage, with specific applications in many groups of animals among which are the following: 1. The passages in the wall of a **sponge.** 2. Slender diverticula of the enteric cavity in **coelenterates** and **ctenophores.** 3. The stone canal, ring canal, and other parts of the water vascular system in **echinoderms.** 4. The inguinal canal through which the testis descends from the abdomen into the scrotum in **mammals.**

In engineering, a canal is an artificial channel conveying or holding water. There are canals built primarily for navigation, and canals whose purpose is to convey water from one point to another. Examples of the former type are to be found in some of the famous ship canals of the world, and examples of the latter type in hydraulic power canals and irrigation canals.

The construction of irrigating canals represents one of man's earliest major engineering achievements. Indeed such construction goes back to earliest recorded history, or even beyond, and the importance of such works is evidenced by present-day remnants and ruins of such structures. Mesopotamia and Egypt afford remains furnishing evidence of some of the earliest irrigation canal construction. Some of the larger of these were doubtless used for navigation as well. At a somewhat later date certain portions of India were covered with an extensive system of irrigation canals. Some of these old irrigation systems have been rehabilitated under modern governments and returned to their original purpose. Construction of extensive irrigation canals in the New World (in Peru, Central America, and the states of Arizona and New Mexico) considerably antedate its discovery in 1492.

Navigable canals constitute the first solution of the problem of transporting freight in bulk overland. Prior to the early development of the railroad, about 1835, there was considerable canal development in Europe and some in the United States. However, the competition of the railroads prevented further development and even rendered obsolete much prior canal construction. At present such navigable canals can compete with railroads only under certain favorable economic circumstances and character of freight.

Navigable canals may be classified according to the relative levels of the two bodies of water which they connect. The Suez Canal is a simple channel connecting the Mediterranean and the Red Sea at practically the same level. The New Orleans Industrial Canal connects a higher and a lower body of water by a simple gradient, but the Panama Canal crosses a continental divide, making the middle some 85′ above the ends which have about the same elevation. A canal such as the Sault Ste. Marie follows a river valley and by-passes the portions of the river which cannot be navigated. The Barge canal is a hybrid type composed partly of artificial canal and partly of canalized river.

Where the profile of a navigable canal is on a gradient, locks must be employed to divide the waterway up into a number of adjacent steps. The lock is a short section of the waterway just large enough to accommodate the longest boat. By means of gates the lock section may be shut off from both adjoining sections of the canal. Valves control the inlet of water to the lock, the operation of which is as follows: A boat proceeding upstream in the canal approaches a lock. The water level in the lock is the same as that in the section containing the boat, so the gates between the boat and the lock are opened, permitting the boat to enter the lock at the lower water level. The gates are then closed, and water is admitted from the higher level. As the water rises in the lock it carries the boat with it. When the water level in the lock equals that in the adjacent canal section, the gates are opened on that end, and the boat is then free to proceed along the canal at the higher level.

Canals built for the purpose of transporting water from one point to another must, for economy, convey the water as rapidly as possible, but not with a velocity great enough to cause erosion. While navigable canals are usually simply excavated in earth and rock, and have little or no water movement within them, water-conveying canals may be eroded if the water exceeds a certain critical velocity. On the other hand, if the water flows too slowly, in some cases there may be a silting up of the canal by earth material released from suspension. There is a critical velocity, however, at which neither silting nor erosion will occur. Many canals having a flow of water are lined with concrete or rock. The rate of flow of water in a canal depends upon the cross-section of the canal, the character of the wetted surface, and the gradient of the bottom. The friction loss in a canal or natural channel is equal to the fall of the surface level of the stream, provided the velocity remains constant. The velocity of water can be found by a number of empirical formulae. Probably the most widely accepted of these is the Kutter-Chezy formula:

$$v = C\sqrt{RS}.$$

v is the mean velocity, ft. per sec., S is the slope, fractional fall per ft. of length, C is a coefficient involving the channel roughness and the hydraulic radius, as well as the slope, R is the hydraulic radius of the cross-section of the canal, and is equal to the cross-sectional area of flow divided by the wetted perimeter. A canal cross-section in the shape of a semicircle is ideal from the standpoint of minimum friction, and concrete lined canals are often so built. However, canals excavated in earth or rock are ordinarily trapezoidal in shape, and velocities of from 1–4 ft. per sec. are employed, depending upon the nature of the soil. (A.W.L., C.W.C., F.T.M.)

CANAL RAYS. This term is a bad translation of the German *Kanalstrahlen.* A more accurate designation would be "tunnel rays" or "perforation rays." They consist of positive particles in a vacuum tube which escape through tunnels or holes bored in the cathode. Positive ions originating in the gas near the cathode move toward it with great speed, ordinarily striking it and causing the surface disintegration and **sputtering** of the metal soon observable; also doubtless releasing **cathode-ray** electrons. But if the cathode is perforated with holes so placed that the positive rays can enter them, some of the particles pass through into the space behind the cathode. In especially constructed canal-ray tubes, this space is elongated so that the positive rays, now isolated from the cathode rays, can be studied separately. (L.D.W.)

CANANGA OIL. Volatile Oils.

CANARY. Aves, Passeriformes. A **finch,** *Serinus canarius,* native to the Canary Islands, which has been extensively used as a cage bird. The wild species is brownish with yellow markings but in captivity pure yellow strains have been developed.

The goldfinch of North America and to a lesser extent the yellow warbler are called wild canaries from their similar yellow color. (A.W.L.)

CANCER. 1. *Astronomy.* (The crab.) (Map, page 380.) Cancer is the name of a small and poorly marked **constellation** of faint stars that is of importance principally because it is the fourth sign of the **zodiac.** In this constellation is found the fine **cluster** known as Praesepe (or the Beehive). The stars are not so numerous as in some other star clusters, but are of sufficient brightness to make this an interesting object in a small telescope. Galileo counted 36 stars with his telescope but observers using modern equipment have counted over 300. On a clear moonless night the object appears as a faint glow of light, and is frequently used by astronomers as a test of the transparency of the **atmosphere.**

2. *Medicine.* (Carcinoma.) Any malignant **tumor** arising from **epithelial** tissue. In its broader sense it includes all disease associated with the presence of such a tumor.

Hippocrates, the 5th century B.C., probably first used the Greek word crab to describe a spreading cancerous growth. From the Romans came the word cancer, meaning crab.

Cancer is one of the most ancient of diseases and its occurrence appears in the earliest records of man. It is one of the most universal and common of all diseases and not only attacks man but all forms of life, including plant life. No age group is exempt. The majority of cases, however, occur in individuals between 40 and 50.

The total deaths from cancer in the United States have been estimated to be around 150,000 annually (1 out of every 8 deaths)—a rate of 125 per hundred thousand. No accurate figures can be given as only about 1% of those dying in this country are autopsied, and many die from unrecognized cancer, the death being attributed to terminal disease such as pneumonia and various circulatory diseases.

In 1900, cancer rated sixth as a cause of death. This increase to second and almost first place is probably accounted for by more accurate diagnosis of cancer as a cause of death, and increase in the average life-expectancy. In other words, more people live longer than previously so that they reach an age when cancer is more likely to develop.

Cancer begins as a simple body cell or group of cells which suddenly starts to multiply without restraint, growing independently of the rest of the body, not serving any useful purpose, invading the surrounding tissues or organs by direct spread, or spreading throughout the body by means of **metastasis** (small groups of cells breaking off from the primary growth and being carried by the blood or lymph channels to far distant tissues

Fig. 1. Photomicrograph of normal stomach wall magnified eighty times. The portion at the top represents stomach cavity. The strand-like processes projecting upward represent the glands and their ducts which secrete the gastric juice. The lighter area below the glands is the muscular wall of the stomach. (*Fortune Magazine.*)

Fig. 2. Section through a cancerous tumor of the stomach, magnified one hundred times. Remnants of normal gland tissue similar to Fig. 1 may be seen in upper right hand corner. The remainder of the illustration shows nests of cancer cells invading the muscular layer of the stomach wall. (*Fortune Magazine.*)

where they in turn produce growths similar to the original or primary tumor). It is this characteristic of spread or metastasis that distinguishes a malignant from a benign tumor. Benign tumors differ from malignant tumors in that (1) they do not metastasize or invade tissue, (2) they usually (but not always) grow slowly, (3) they interfere with function only through pressure or obstruction of surrounding structures, (4) they usually threaten life only by compression of some vital structure because of their increasing size. This is especially true when they grow in a confined or closed space. In most instances it is easy to distinguish between benign and malignant tumors. In other cases, the growth may be borderline between the two classifications, and it may be difficult for an expert to distinguish between the two. In this borderline group an accurate diagnosis cannot be made by physical examination of the patient or any other method except surgical **biopsy** and microscopic examination of the tissue removed.

In spite of observations and theorizing for the past 2000 years, the causes of cancer are still unknown. The Greeks and Romans attributed cancer to a disturbance of the humoral balance of the body, and today various theories are similar, in that they presuppose alterations in the secretions of the endocrine glands as a partial cause for the abnormal cell growth. Modern research has demonstrated that chemical irritation and the irritation of chronic inflammation often are starting points for at least some malignant tumors.

One theory of long standing is that of Cohnheim, assuming that tumors start from misplaced embryonic cells which may remain dormant for years. With some stimulus that is unknown, these **embryonic** cells start their unrestrained growth and become a malignant tumor. Such embryonal displacement of cells is not uncommon and may well account for the start of some tumors. A serious objection to this hypothesis is the

fact that tumors can be caused in almost any portion of the body by chronic irritation.

Another theory assumes that cancer is due to the action of some unknown parasite, a **virus** which causes irritation of tissues or invades the cell and causes it to proliferate abnormally.

It is true that in experimental animals, certain malignant tumors have been produced by viruses. Rous demonstrated the transmission of chicken sarcoma by a filtrate of tumor tissue which had passed through a Berkfeld filter. More recently, an agent has been found in the milk of certain strains of mice which develop spontaneous breast cancer. This "milk factor" has the properties of a virus. It induces breast cancer in the young suckled by their mothers, and also in the young of certain normal strains suckled by mice whose milk contains the milk factor. However, if the young of the cancerous mothers are suckled by normal mice, they do not develop cancer. Thus ingestion of the infectious agent in the milk is necessary for the development of malignant tumors in these susceptible animals.

A recent theory, that of Gye, is that an ultramicroscopic virus, or group of viruses, plus some unknown factor inherent in the animal's tissues are necessary to produce the malignant tumor. Much of the recent experimental work supports the virus etiology of malignant growths. It is believed by some investigators that the infectious agent is acquired very early in life by an individual whose hereditary pattern plays some role in making him susceptible. The infection itself is thought to remain latent until later in life, when any one of a number of physical or chemical factors may cause its activation.

The occurrence of cancer in man seems to be influenced by heredity in some instances, but the fact that every family tree shows malignant disease in some of its members, if adequate search is made, makes the apparent greater susceptibility in some families hard to evaluate. Considerable work has been done on inheritance of cancer in mice by Maud Slye, who has developed a strain all the members of which have spontaneous cancer.

The relationship between an injury and the occurrence of cancer is sometimes based on faulty or superficial observation, or accidental coincidence. A single injury cannot be said to initiate a cancerous growth, but chronic irritation has long been observed to be related to new growths. Examples of this are cancer of the lip in pipe smokers, skin cancers in x-ray workers and chimney sweeps, who develop the disease in sites exposed to irritation.

In a very small proportion of malignant tumors spontaneous disappearance of the growth has occurred. This has been estimated to happen not oftener than once in 100,000 cases.

The clinical picture presented by a patient with a malignant tumor varies widely depending on the site of the tumor. The first sign of cancer on the body surface or in the breast, tongue, or lip is a lump or slight thickening of the tissue. Cancer in a vital internal organ is particularly difficult to diagnose early. Pain is an extremely late symptom. In intestinal, stomach, or rectal cancer, the first symptom may be persistent indigestion or abdominal distress which is treated by the patient with frequent doses of soda and other alkalies until it is too late for proper treatment. Lack of appetite and disturbances of taste may be other signs.

Cancer in other parts of the body may be first marked by unusual discharges or slight bleeding. Sores or ulcers that refuse to heal may have undergone malignant change. Bleeding from the nipple, or the rectum, or unusual discharge of blood from the female genital organs are suggestive of cancer as well as other diseased conditions. Diagnosis can be made by a competent physician or surgeon. Cancer of the rectum is often treated as hemorrhoids or constipation. Cancer of the bone may cause vague aching pain early, and is often treated as "rheumatism." X-ray is of utmost value in diagnosis of bone cancer.

Diagnosis of cancer requires a complete physical examination and, depending on the location, x-ray or other special diagnostic procedures. When a positive diagnosis cannot be made, as is sometimes the case, it is necessary to do a **biopsy**. By this means an exceedingly small piece of tissue is removed, cut and stained and then examined under the microscope by an expert pathologist.

The earlier cancer is found, the more difficult it is to recognize. When diagnosis is easy the disease often is too far advanced for any but palliative treatment.

Often the doctor is at fault, through not noticing salient points in the history of a case, not doing a thorough examination or making use of special examinations. But more often it is the patient who is at fault, either through ignorance, fear, or use of home remedies or remedies advertised for constipation, piles, indigestion, etc.

Treatment of cancer involves surgery, radium or x-ray or a combination of surgery and radiation. Different forms and location of the tumor may require one or the other or both.

Cancer of the skin or of the **cervix** of the uterus is often best treated by radium. Palliative treatment of certain foci of inoperable cancer is done by use of x-ray or radium.

In general, cancer of the internal organs is best treated by surgery. Radiation by x-ray or radium in some cases is used before operation and after operation. Cancer is curable but only when it exists as a primary localized growth. When it has begun to spread over the body death usually results sooner or later, although the patient may live for several years or more with but few symptoms and in relative comfort.

In certain forms of cancer electrosurgery is used in the form of the endotherm knife (radio knife) for coagulation and removal of tumors. It is particularly used in less accessible growths as in the larynx, brain, chest, and bladder. (W.K.G., R.S.M., D.M.H.)

CANCRINITE. The mineral cancrinite is a complex orthosilicate (see **Silicon**) corresponding approximately to the formula $3H_2O \cdot 4Na_2O \cdot CaO \cdot 4Al_2O_3 \cdot 9SiO_2 \cdot 2CO_2$. It is **hexagonal**, with prismatic cleavage; hardness, 5–6; specific gravity, 2.42–2.50; color, white to gray or may be greenish, bluish, yellow, or flesh red; colorless streak; luster, subvitreous to greasy; transparent to translucent. Cancrinite is found only in the **nephelite-syenites** and related rock types and commonly associated with **sodalite.** Cancrinite is believed to be in part primary, having crystallized direct from the **magma,** and in part secondary as a result of alteration of nephelite by solutions of calcium carbonate. Cancrinite is found in the Ilmen Mts. of Russia, in Rumania, in Norway and in Canada in Hastings County, Ontario, and in the United States in Kennebec County. This mineral was named for Count Georg Cancrin, a Russian statesman who died in 1845. (E.S.C.S.)

CANDLE POWER. Chief among the problems of **photometry** has been the development of a suitable standard of luminous intensity. In the earlier stages of the science it was sufficient to rate a lamp as equivalent to so many ordinary candles. Later it became necessary, in the interest of accuracy, to agree upon specifications for the English standard candle, as to its composition, wick structure, rate of burning, etc. At best such a standard could be only approximately uniform. The pentane lamp (approximately one candle power), the French Carcel lamp, burning colza oil, and the German Hefner lamp, burning amyl acetate, as well as standardized gas flames, were subject in less degree to the same limitations.

In 1921 the International Commission on Illumination adopted the international candle, which had for some

years been in practical use in the national standards laboratories of the United States, Great Britain, and France. It was defined in terms of carbon-filament lamps constructed and operated under specified conditions. The United States candle was thus fixed in reference to a group of 45 lamps kept at the National Bureau of Standards, and has been our standard until 1940.

J. Voille long ago proposed as a unit of intensity 1 sq. cm. of surface of molten platinum at its melting point. Waidner and Burgess improved on this idea by replacing the platinum surface by a **black-body** radiator, and their suggestion has now been embodied in the "new candle," adopted in 1937 by the International Committee on Weights and Measures to be put into effect shortly. This standard is defined as $\frac{1}{60}$ of the luminous intensity of 1 sq. cm. of the black-body radiator at the melting point of platinum. (See **Photometry** and **Illumination.**) (L.D.W.)

CANDLEFISH. Pisces, Teleostei. An oily **fish,** *Thaleichthys pacificus,* belonging to the **smelt** family. It is found from Oregon to Alaska and ascends the coastal streams. It is an important food fish and takes its name from the fact that it can be burned as a candle when dried. (A.W.L.)

CANDLE-FLY. A southern name for **moth,** equivalent to the northern miller or moth-miller. (A.W.L.)

CANE CUTTER. Cottontail.

CANE-RAT. Mammalia, Rodentia. An African burrowing species more closely related to the **porcupines** than to the true rats. (A.W.L.)

CANGA. A Brazilian term for an iron-rich conglomerate or breccia in which the pebbles or **anguclasts** are **hematite** and **itaberite** cemented by hematite or **limonite.** (R.M.F.)

CANINE. 1. Pertaining to dogs. 2. An elongate conical tooth between the incisors and premolars of each half-jaw. The eye-teeth of man in the vernacular. (A.W.L.)

CANIS MAJOR. (The great dog.) (Map, page 380.) Both this **constellation** and its companion Canis Minor, or the little dog, have been named from remote antiquity as the dogs of **Orion.** **Sirius** in Canis Major and **Procyon** in Canis Minor are both well-known stars, Sirius being the brightest observable. References to these stars are to be found in nearly all ancient classical literature. Sirius, in particular, was of great importance to the Egyptians because it rose with the sun at the period when the waters of the Nile were due to rise and was considered as a herald of the returning fertility of the valley. Sirius is not only the brightest, but also the closest star visible to the naked eye which can be observed in the **latitudes** of Europe or North America. Intrinsically Sirius has a brightness more than 20 times that of our sun. Both Sirius and Procyon have faint companions, that of Sirius being particularly famous as the first of the **white dwarfs** discovered. (W.K.G.)

CANKER-WORM. Insecta, Lepidoptera. **Insects** of two chief species, the spring canker-worm, *Paleacrita vernata,* and fall canker-worm, *Alsophila pometaria,* respectively, which attack apple trees and are sometimes important pests. The spring canker-worm is found throughout the United States and the fall canker-worm in the northeastern quarter of the country.

The caterpillars eat leaves and so can be destroyed by spraying with arsenate of lead. Since the females are wingless, bands of tanglefoot around the tree trunks prevent their ascending the trees to deposit their eggs.

Canker-worms of three other species occur in North America. (A.W.L.)

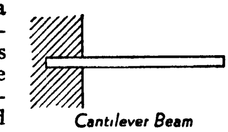
CANNABIS INDICA. A variety of common **hemp** from which is procured the so-called hashish and marijuana, etc.—habit-forming narcotic **drugs.** They are not commonly used in medical practice. (D.M.H.)

CANNEL COAL. A form of bituminous or soft **coal** which ignites easily and burns with a hot "candle-like" flame, due to its high percentage of volatile matter. Especially desirable for open fires and metallurgical processes. Most cannel coals owe their desirable peculiarities to their large content of paraffine-like fossil spore cases which are highly volatile. The peculiar chemical and organic composition of this type of coal strongly suggests that it originated as a lake muck (sapropel) under open water rather than typical peat bog conditions. (R.M.F.)

CANTALOUPE. Gourd Family.

CANTHARIDES. Spanish Fly.

CANTILEVER BEAM. A beam which is rigidly connected at one end to a fixed support and free to move at the other end is called a cantilever beam. This theoretically fixed condition rarely occurs because of deformation of the supporting material. The maximum **bending moment** and maximum **shear** occur simultaneously at the face of the support. The usefulness of this type of beam is demonstrated in structures such as canopies, unbraced airplane wings and cantilever **retaining walls.** (C W.C.)



Cantilever beam.

CANTILEVER BRIDGE. Bridge.

CANVAS-BACK. Aves, Anseriformes A large North American **duck,** *Nyroca valisneria,* similar to the redhead but with a dusky crown and face. Its flesh at the proper season is superior to that of other ducks. (A.W.L.)

CAP SCREW. Screw Fastenings.

CAPACITANCE. Also often called "electric capacity," the capacitance of an electrically conducting body is the ratio of the quantity of electricity imparted to the body to the resulting change in its electric potential. It is usually expressed in coulombs of charge per volt of potential change, that is, in terms of the **farad,** or its submultiples; the fundamental c.g.s. electromagnetic unit being, however, the "abfarad." (See **Electrical and Magnetic Units.**)

If a conductor is completely isolated, that is, far removed from other conductors, including the earth, and is surrounded by a homogeneous, perfectly insulating **dielectric,** its capacitance depends only upon the size and shape of its external surface and upon the **dielectric constant** of the surrounding medium. For some bodies of definite geometrical form, the capacitance may be calculated. For example, the capacitance of an isolated sphere, in farads, is equal to $kr/(9 \times 10^{11})$, in which r is the radius in cm. and k is the dielectric constant of the surrounding medium. The capacitance of a conductor may be greatly increased by bringing it near to other conductors (in which case it forms part of a **condenser**).

Very long electric circuits, especially when the wire is surrounded by a conducting sheath, as an ocean cable, have considerable capacitance because of the condenser-like action of wire and sheath with the insulation between them acting as dielectric. The same is true of insulated wire wound in a close coil, adjacent turns of which, being at slightly different potential, act as the conductors of a condenser; an effect which

may be partially avoided by a criss-cross or "honeycomb" winding or by a "banked" winding (in flat spirals). The capacitance of a circuit, whether thus "distributed" or intentionally introduced by means of condensers, acts as a condenser in parallel with the conductor, and may have marked effect upon alternating or variable currents traversing it. (See **Electric Circuits** and **Alternating Currents.**) (L.D.W.)

CAPACITIVE LOAD. An alternating-current circuit in which the current drawn leads the voltage in phase is said to provide a capacitive load. Capacitive loading may be the result of actual **condensers**, or of virtual condensers in the form of long transmission lines, or over-excited synchronous rotating equipment. Most electrical apparatus, such as **motors, coils**, etc., draws from the line a current which lags the voltage, and the use of some capacitive load is desirable in order to bring the total current and voltage more nearly in phase, and thus raise the **power factor.** (F.T.M.)

CAPACITY, DISTRIBUTED. Coil.

CAPACITY, ELECTRIC. Capacitance.

CAPE POLECAT. Mammalia, Carnivora. A South African animal resembling the **skunks** and apparently intermediate between them and the true **polecats.** Like these relatives they have a foul odor. (A.W.L.)

CAPELLA. Capella (**α Aurigae**) is the third brightest star visible in the northern latitudes, and the fifth brightest star on the celestial sphere. It is closer to the pole than any of the other bright stars. Capella has always played an important part in mythological writings and we find it referred to on an old tablet dating back to 2000 B.C. **Astrologically,** Capella portended civic and military honors and wealth.

Astronomically, Capella is particularly interesting for it is a star which is a **spectroscopic binary** with a period of 104 days, and the angular distance between the components has been measured with the interferometer. From the complete solution of the **orbit**, the physical characteristics of the object may be found. It is a **giant** star of the same **spectral class** as our sun. (W.K.G.)

CAPERCAILLIE. Aves, Galliformes. A large woodland **grouse** of northern and central Europe and Asia. The species is also known as the capercally, capercailizie, wood-grouse and cock-of-the-wood. *Tetrao urogallus.* (A.W.L.)

CAPILLARITY. The name given to a class of phenomena, of which the elevating or depression of liquids in fine tubes is representative. When the interface between a liquid and a gas, or between two liquids, is intercepted by a solid surface, an equilibrium is established at the junction among the forces acting along the three surfaces of contact. For example, let a plate of solid S be dipped into a liquid L having gas G above it (see Fig. 1). A molecule at the junction O is

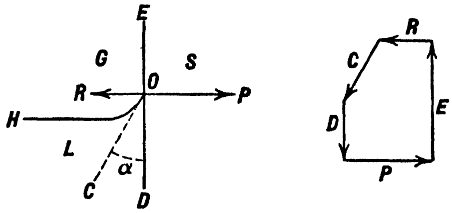


Fig. 1. Capillary force, large adhesion.

acted upon by the adhesive attraction P, by the forces which give rise to the three **surface tensions** along the interfaces OH, OE, and OD, and by the reaction R of the plate S against which it is drawn by the adhesion. (Its weight may be considered negligible.) The flexible interface OH adjusts itself so that these forces come into equilibrium; unless, indeed, one of them, E, exceeds the sum of D and C, in which case the liquid "creeps" indefinitely along the surface as oil does over a glass or tin container. The equilibrium polygon at the right is labeled in each case to correspond with the figure representing the surfaces. The "angle of contact" α, between the liquid surface at O and the solid surface OD, is determined by the aforesaid forces acting at O. For most liquids against glass it is acute; for mercury against glass it is obtuse. (Fig. 2.) In special cases it may be 90°, and in others it reduces to zero.

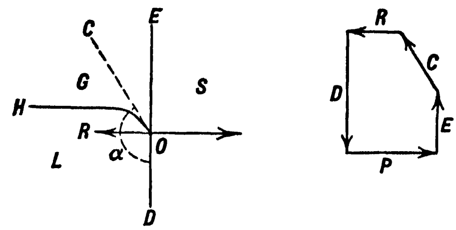

Fig. 2. Capillary forces, small adhesion.

If the interface between two media A and B (Fig. 3) is curved, A being on the concave side, the pressure in A is greater than in B on account of the surface tension; much as the pressure inside a rubber balloon is greater than outside. We can now understand why water rises in a capillary tube. For, to secure equilibrium, the liquid must rise until the pressure inside the surface at B, plus the pressure due to gravity at depth h, makes the pressure at L equal to that at the surface level outside; that is, to the atmospheric pressure. Similar reasoning applies to the depression of mercury in a glass tube. For a circular tube of internal radius r, the distance h to which capillarity will elevate (or depress) a liquid of density ρ and surface tension T (against air) is readily shown to be

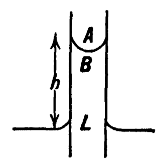

Fig 3. Rise of liquid in capillary tube.

$$h = \frac{2T\cos\alpha}{r\rho g},$$

where g is gravity. (See also **Electrocapillarity.**) (L.D.W.)

CAPILLARY. 1. Hair-like, especially in application to fine tubes. 2. A minute blood vessel intervening between the arteries and veins. (See **Circulatory System.**) (A.W.L.)

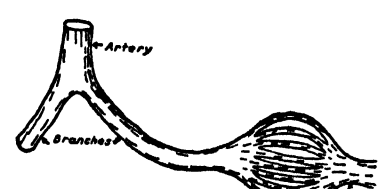

Diagram to illustrate variations in velocity of bloodflow. If a vessel divides into two branches, these will be individually of less cross-section than the main trunk, but united they will exceed it. Linear velocity will be lower in the branches than in the parent stock. The sum of the cross-sectional areas of the capillaries is greater than that of the artery or vein. (*Kimber and Gray, Textbook of Anatomy and Physiology, Macmillan & Co.*)

CAPILLARY ELECTROMETER. Electrocapillarity.

CAPILLARY FRINGE. Above the zone of saturation, capillary pores may exist which, if filled with water, form a zone or fringe of moisture higher than the true

water table. This is the capillary fringe or zone of capillarity. (E.S.C.S.)

CAPITULUM. 1. A protuberance on **mites** and **ticks** which appears to be a small head but is formed only of the mouth parts. 2. Any small head, or small, bony, articular eminence, such as the capitulum of a rib. (A.W.L.)

CAPRICORNUS. (The sea-goat.) (Map, page 380.) This is a **constellation** of small stars, not at all striking in appearance, but important because it is the tenth of the **zodiac.** The star Alpha (named Giedi) is one of the more remarkable stars, it being actually made up of six components. The two larger can be seen by some keen-eyed persons as separate, but it is easily resolved by means of an opera glass. Each of these two components may be still further resolved into three component parts with appropriate telescopes. (W.K.G.)

CAPRIMULGIFORMES. An order of nocturnal birds (**Aves**) with very wide mouths. The **nightjars,** including the **whip-poor-will** and **nighthawk,** the **goat-suckers,** and the oil **birds.** (A.W.L.)

CAPSAICIN. Potato Family.

CAPSICUM, CAPSAICIN. Potato Family.

CAPSTAFF EFFECT. A photographic effect discovered by J. G. Capstaff in 1921. Sulfurous acid followed by a weak alkali is capable of extending the sensitivity of blue sensitive films and plates to longer wavelengths. The effect appears to be due to the formation of a form of colloid silver and is of no practical value, although materials sensitive to the entire visible region (panchromatic) can be produced by bathing successively in sodium bisulfite (2%) and a weak solution of sodium carbonate, then washing in running water. (C.B.N.)

CAPSTAN. A capstan is a machine, usually rotary, used chiefly in connection with shipping for hoisting heavy weights. Although formerly turned by hand with a capstan bar, the capstan is now frequently operated by a steam engine or electric motor. The capstan may have a reduction gear so that it can be operated at two different speeds, and thus be suited to the loads to be hoisted. (F.T.M.)

CAPSULE. Fruit.

CAPTACULA. Filaments with suckers at the tips, found on the dorsal surface of the head in the tooth-shells, marine **mollusks** of the class Scaphopoda. (A.W.L.)

CAPUCHIN MONKEY. Mammalia, Primates. Any of several species of South American **monkeys** of the genus *Cebus,* which are characterized by the moderately long prehensile tail. They differ from the other species with prehensile tails in having this organ fully covered with hair and not bare on the lower surface near the tip. Also called sapajous. (A.W.L.)

CAPYBARA. Mammalia, Rodentia. A large South American species, *Hydrochoerus capybara,* of the **cavy** family. These animals attain a length of 4′ and a weight of almost 100 lbs. They are semiaquatic in habits and while their food usually consists of water plants and other vegetation they sometimes make inroads on cultivated crops. They are also called capivara and carpincho. (A.W.L.)

CARABAO. Buffalo.

CARACAL. Mammalia, Carnivora. A member of the cat family found in India and thence into Africa where it is widely distributed. It is related to the **lynxes** and like them is marked by tufted ears. Sometimes known as the Persian lynx. *Lynx caracal.* (A.W.L.)

CARACARA. Aves. Falconiformes. South American birds (**Aves**) of several species related to the hawks. They eat carrion but also catch living prey and sometimes rob other birds of their prey. One species, Audobon's carcara, *Polyborus cheriway,* occurs in the extreme southern parts of the United States. (A.W.L.)

CARACUL. Karakul.

CARAPACE. A shield-like covering of the upper part of the body. In the crustaceans it is the body wall of the thorax and in the **turtles** and **tortoises** it is a complex structure made up of bony plates, including flattened ribs and vertebrae, covered with thin horny plates. The armor of the **armadillo,** composed of many bony plates developed from the skin and covered with horny plates, is also called a carapace. (A.W.L.)

CARAPATO. Arachnida, Acarina. **Ticks** of two species, found in tropical Africa and Central America, respectively. The African species is also called the tampan.

The wounds produced by these creatures are severe in themselves but their transmission of the germs of **relapsing fever** is a much greater danger. (A.W.L.)

CARAWAY. Carrot Family.

CARAWILA. Halys, Pit Viper.

CARBAMIC ACID. Amines and Amides.

CARBAZOLE. Pyrrole and Related Compounds.

CARBIDES. Carbon.

CARBINOLS. Alcohols.

CARBOHYDRATES. Carbohydrates are polyhydroxy **aldehydes** or **ketones,** or those products which are chemically related to such simple units by combination of two or more of these units through the loss of water. These higher units are thus **anhydrides.** They yield the simple units, referred to above, by treatment with acids, such as **hydrochloric** or **sulfuric,** or particular **enzymes.**

Carbohydrates respond to the alpha-naphthol test as given under glucose, reaction number (12) below, when heated (1) in air, carbohydrates burn to form **carbon dioxide** plus water, evolving heat, (2) in the absence of air, combustible gases, watery and tarry distillates, and charcoal residue.

Carbohydrates may be classified as follows:

Monosaccharides (sugars).
- Crystalline solids, soluble in water, sweet taste. Those that occur in nature are fermentable by certain enzymes.
- Tetrose, $C_4H_8O_4$
  - 1. Erythrose
- Pentoses, $C_5H_{10}O_5$
  - 2. Arabinose
    - By boiling gum arabic, cherry gum, corn pith, elder pith with dilute sulfuric acid.
  - 3. Xylose
    - By boiling substances mentioned under arabinose above.
  - 4. Ribose
  - 5. Lyxose
- Hexoses, $C_6H_{12}O_6$
  - Aldohexoses
    - 6. Glucose, dextrose ("grape sugar"), melting point 146° C. (anhydrous). With the **enzyme** zymase (of yeast) yields ethyl **alcohol** plus **carbon dioxide.** Specific rotatory power—see glucose below.
    - 7. Galactose
      - Specific rotatory power $+ 83.9°$.
    - 8. Mannose
      - Specific rotatory power $+ 14.1°$.

9. Gulose
10. Idose
11. Talose
12. Altrose
13. Allose

Ketohexoses

14. Fructose, laevulose ("fruit sugar"), melting point 95° C. Specific rotatory power − 88.5°.
15. Sorbose
16. Tagatose

Disaccharides (sugars), $C_{12}H_{22}O_{11}$

Crystalline solids, soluble in water, sweet taste.

17. Sucrose ("cane sugar," "beet sugar"), melting point 170–186° C. (decomposes). With the enzyme invertase, yields glucose plus fructose. Specific rotatory power + 66.4°.
18. Lactose ("milk sugar"), melting point 202° C. (anhydrous). With the enzyme lactase yields glucose plus galactose. Specific rotatory power + 52.4°.
19. Maltose ("malt sugar"), melting point of $C_{12}H_{22}O_{11}\cdot H_2O$: 100° C. With the enzyme maltase yields glucose plus glucose. Specific rotatory power + 138.5°.
20. Melibiose
    With enzymes or dilute acid yields glucose plus galactose.
21. Cellobiose
    With the enzymes maltase, or cellase, yields glucose plus glucose.
22. Trehalose.

Trisaccharide, $C_{18}H_{32}O_{16}$

Crystalline solid, soluble in water, tasteless.

23. Raffinose, melitose, melting point 118° C. (anhydrous). With the enzyme invertase, yields fructose plus melibiose. With the enzyme emulsin, yields sucrose plus galactose.

Polysaccharides (non-sugars), $(C_6H_{10}O_5)_n$

Non-crystalline solids, insoluble in water, tasteless.

24. Starches
    With the enzyme diastase yield maltose.
25. Celluloses
    With hydrochloric acid, heated, yield glucose.
    With acetic anhydride plus concentrated sulfuric acid, yield cellobiose.
26. Dextrin
    With the enzyme diatase yields maltose.
    With the enzyme maltase or with acids yields glucose.
27. Inulin, melting point 178° C. (decom.) $(C_6H_{10}O_5)_n$
    With the enzyme inulase (but not with diastase) yields fructose.
28. Glycogen, melting point 240° C.
    With the enzyme diastase (or ptyalin), yields glucose plus maltose.
29. Pentosans

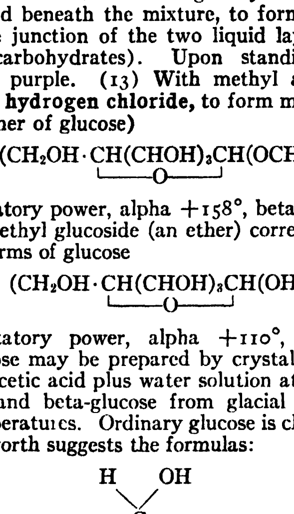
Glucose may be called the key carbohydrate, since it is the leading member of the aldohexose group, and is formed as one of the products or the only product when the following carbohydrates are hydrolyzed, sucrose, lactose, maltose, cellulose, glycogen. Glucose is a colorless solid ($C_6H_{12}O_6$), less sweet than sucrose, soluble in water from which it may be crystallized ($C_6H_{12}O_6\cdot H_2O$), melting point 86° C., slightly soluble in alcohol from which it may be crystallized anhydrous of melting point 146° C. Either of these crystalline forms, upon examination of the solution in the polariscope, shows a specific rotary power of +110° when the solution is freshly prepared, but the solution changes, gradually upon standing or rapidly upon heating, to a constant value of +52.5°, a phenomenon known as mutarotation. Glucose reacts (1) with alkaline **cupric** salt solution (**Fehling's solution** or **Benedict's solution**) to form **cuprous** oxide, (2) with ammonio-silver salt solution (Tollens' solution) to form finely divided or mirror film of silver, (3) with **phenylhydrazine** in acetic acid, to form glucose phenylhydrazone ($CH_2OH(CHOH)_4CH{:}NNHC_6H_5$), white solid, melting point alpha 159–160° C., beta 140–141° C., with excess phenylhydrazine to form glucosazone ($CH_2OH(CHOH)_3C{:}NNHC_6H_5\cdot CH{:}NNHC_6H_5$) yellow solid, melting point 205° C. decom., (4) with acetic **anhydride**, to form glucose pentacetate ($C_5H_6(OOCCH_3)_5CHO$), melting point alpha 112 to 113° C., beta 131 to 134° C., (5) with **sodium** amalgam, to form sorbitol ($CH_2OH(CHOH)_4CH_2OH$), (6) with **hydriodic acid**, to form 2-iodo-normal-hexane ($CH_3(CH_2)_3CHICH_3$), (7) with **sodium** hydroxide solution, to form yellowish-brown solutions upon warming, (8) with **calcium** hydroxide solution, to form calcium glucosate ($CH_2OH(CHOH)_4COCa(OH)$), slightly soluble solid from which glucose is recoverable by action of **carbon dioxide** (calcium carbonate formed simultaneously). **Strontium** hydroxide and **barium** hydroxide react similarly. Any of these three reactions may be utilized to recover glucose, with the limitation that barium soluble compounds are poisonous, (9) with **hydroxylamine** hydrochloride, to form glucoseoxime ($CH_2OH(CHOH)_4CH{:}NOH$), melting point 138° C., (10) with hydrocyanic acid, to form glucosecyanhydrin ($CH_2OH(CHOH)_4CHOHCN$), (11) by oxidation, to yield with **bromine** gluconic acid ($CH_2OH(CHOH)_4COOH$), and with **nitric acid** saccharic acid ($COOH(CHOH)_4COOH$), (12) with alpha-naphthol dissolved in chloroform and then forming a layer of concentrated sulfuric acid beneath the mixture, to form a red coloration at the junction of the two liquid layers (Molisch's test for carbohydrates). Upon standing, the color changes to purple. (13) With methyl **alcohol** in the presence of **hydrogen chloride**, to form methyl glucoside (methyl ether of glucose)

$$(CH_2OH\cdot \underbrace{CH(CHOH)_3CH}_{O}(OCH_3)),$$

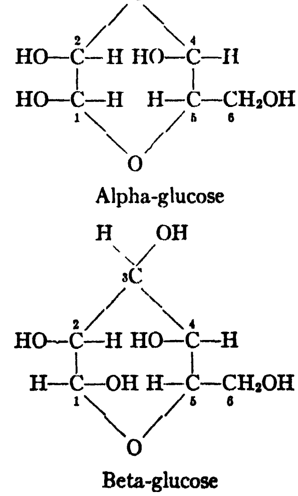
specific rotatory power, alpha +158°, beta −34°. Alpha and beta methyl glucoside (an ether) correspond to alpha and beta forms of glucose

$$(CH_2OH\cdot \underbrace{CH(CHOH)_3CH}_{O}(OH)),$$

specific rotatory power, alpha +110°, beta +17.5°. Alpha-glucose may be prepared by crystallization of glucose from acetic acid plus water solution at ordinary temperatures, and beta-glucose from glacial acetic acid at higher temperatures. Ordinary glucose is chiefly the alpha form. Haworth suggests the formulas:



Alpha-glucose



Beta-glucose

The following methylglucosides have been prepared and used in the study of the structure of glucose, namely, 2,3,4,6-tetramethylglucose or galactose

$$(CH_2OCH_3 \cdot CH(CHOCH_3)_2CHOH),$$
$$\text{O}$$

2,3,6-trimethylglucose

$$(CH_2OCH_3 \cdot CH \cdot CHOH(CHOCH_3)_2CHOH),$$
$$\text{O}$$

2,3,4-trimethylglucose

$$(CH_2OH \cdot CH(CHOCH_3)_3CHOH),$$
$$\text{O}$$

1,3,4,6-tetramethylfructose

$$(CH_2OCH_3 \cdot CH(CHOCH_3)_2C(OH) \cdot CH_2OCH_3).$$
$$\text{O}$$

Glucose possesses four asymmetric carbon atoms (2, 3, 4, 5), making possible 16 different stereoisomerides. These are represented by the two forms (dextro and laevo) of each of the 8 aldohexoses listed. In structure these differ solely in the arrangement of the groups —H and —OH about the four asymmetric carbon atoms. Similarly, the aldopentoses consist of 4 pairs, or 8 in all, stereoisomerides, namely, dextro- and laevo-arabinose and the pairs of each of the three sugars, which follow in the list.

Glucose and fructose are present in sweet fruits, such as grapes and figs, and in honey. These two are the only hexoses found in nature in the free state. Glucose is normally present in human urine to the extent of about 0.1%, but in the case of those suffering from **diabetes** glucose is secreted in large amount. Glucose is formed, as previously mentioned, by the reaction of polysaccharides and water, the reaction with starch in the presence of very dilute hydrochloric acid serving as the industrial source (the hydrochloric acid acts as a catalyzer, and the small percentage present is later neutralized to form sodium chloride). The solution is evaporated to a syrup or to crystallization, and is used in the manufacture of sweets, and (usually) alcohol, and in foods. The reaction of glucosides with water, by enzymes or acids, produces glucose as one of the products. With **sodium** hydroxide, under carefully defined conditions, glucose forms **lactic acid.** Glucose is used as food and for the production of alcohol of wines from fruit juices. Glucose may be detected by formation of glucosazone, and determination of its melting point.

Fructose is present with glucose in sweet fruits and honey, may be obtained free by reaction of inulin of dahlia tubers or artichokes with water, and with glucose by reaction of sucrose with water, the product being known as invert sugar. Fructose differs from glucose in structure in being a pentahydroxy-2-ketone, $CH_2OH(CHOH)_3COCH_2OH$ instead of aldehyde. The specific rotatory power of fructose is —88.5°. Fructose forms the same identical osazone as glucose, and sorbitol plus mannitol by reduction. Fructose may be used as sugar by diabetic patients to advantage instead of glucose or sucrose. Fructose is detected by the violet color its alkaline solution gives with meta-dinitrobenzene.

Sucrose is a colorless solid, when heated melts at 170° to 186° C., and on cooling forms barley sugar which gradually crystallizes, upon heating above the melting point forms caramel, a brown liquid, with decomposition. Caramel is used in confectionery, and in coloring beverages and foods. At higher temperatures decomposition into gaseous and tarry substances occurs, finally leaving a residue of carbon ("sugar charcoal"). Other sugars behave similarly. Sugars are also carbonized by concentrated sulfuric acid. Sucrose is very soluble in water, and is obtained from solution by crystallization, usually by vacuum evaporation. The solution has a specific rotatory power of +66.4°, does not exhibit mutarotation, but is converted by acids or invertase into invert sugar (glucose plus fructose), specific rotatory power —19.7°. Sucrose forms with calcium hydroxide calcium sucrosate, a 1% solution of sugar dissolves about 18 times as much calcium hydroxide as does pure water. This behavior is utilized to recover sugar from solutions, as in the case of glucose, and also to determine free calcium oxide in burnt lime, due to the reactivity of calcium hydroxide and non-reactivity of calcium carbonate. Sucrose is non-reactive with dilute sodium hydroxide, with phenylhydrazine, with ammonio-silver salt solution, but when inverted to glucose plus fructose, these reactions may be obtained. Sucrose forms with acetic anhydride sucrose octaäcetate. The suggested structural formula is

$$\begin{array}{ccc} & CH_2OH & CH_2OH \\ & | & | \\ CH_2OHCHOHCH(CHOH)_2CH—O— & C & (CHOH)_2CH \\ \text{O} & & \text{O} \end{array}$$

Glucose residue | Fructose residue

Sucrose is an important food preservative, food flavor, and a raw material for confectionery and for industrial alcohol.

Sucrose is extensively distributed in the seeds and leaves of plants, and is the most abundant of the sugars. The commercial sources of sucrose are the stems of sugar-cane (11 to 16% sucrose, average 13%), the root of the sugar-beet (average 16% sucrose, selection having raised the sucrose content from 5% to a maximum of 20%), the sap of the sugar maple, and the stems of sorghum-cane. Sucrose is pressed from the stems of sugar-cane or sorghum-cane, and extracted with the water from the sliced roots of sugar-beets. The solutions are purified, evaporated and crystallized to such a degree that commercial sucrose is practically chemically pure (about 99.8% sucrose). The purity of sugar and the concentration or strength of sugar solutions is determined by the rotatory power of the solution, the special polariscope usually used being called a saccharimeter. Sucrose is reduced with Fehling's solution only after inversion.

The sugar content of some common fruits have been reported by Kulisch:

	Sucrose	Hexoses
Apple	1.0–5.4	7.0–13.0
Apricot	6.0	2.7
Banana, ripe	5.0	10.0
Pineapple	11.3	2.0
Strawberry	6.3	5.0

Lactose is obtained from the residual water solution ("whey") of milk after removal of fat and casein for butter and cheese. Milk contains about 4.5% of lactose. Lactose forms hard gritty crystals ("sand sugar") ($C_{12}H_{22}O_{11} \cdot H_2O$), loses water at 140° C., melting point 202° C. (anhydrous) with decomposition; is less sweet than sucrose, reduces ammonio-cupric salt solution, ammonio-silver salt solution, forms osazone, melting point 200° C., turns yellow when warmed with sodium hydroxide solution. Lactose is the source of galactose, and undergoes, with the proper **enzymes,** fermentation into **lactic acid** and **butyric acid.**

Maltose is found in soy bean, and is produced by the action of the enzyme diastase of germinated barley (malt) on starch at 50° C., and is thus an intermediate product in the transformation of starch into alcohol. Maltose ($C_{12}H_{22}O_{11} \cdot H_2O$), melting point 100° C., when rapidly heated, may be crystallized from the concentrated malt syrup after removal of proteins and insoluble material. Maltose reduces ammonio-cupric salt solution, and forms osazone.

Starch is a white powder, odorless and tasteless, insoluble in cold water, forming an emulsion ("starch paste") or gel with hot water, the consistency of which depends upon the ratio of starch to water used. When boiled starch emulsion is cooled and treated with a solution of

iodine in alcohol or potassium iodide, a blue coloration is produced, which is a sensitive and characteristic test. The blue color is associated with the adsorption of iodine on the surface of the starch, and disappears in the presence of alkalis. When boiled with dilute acid, starch is first changed into a soluble gummy mixture known as dextrin, and finally into glucose. When starch, either alone or in the presence of a slight amount of nitric acid, is heated to 120° to 200° C., dextrin is formed; at higher temperatures starch behaves similarly to sucrose. With concentrated nitric acid, starch forms esters, similar to cellulose nitrates. By the action of the **enzyme** diastase, starch is converted into maltose, which with the enzyme maltase yields glucose. Starch is non-reactive with ammonio-**cupric** salt solution, and with **phenylhydrazine.** Starch is extensively distributed as granules in many plants. Those that serve as important reserves of starch are the seeds of wheat, corn, barley, rye, rice, the tubers of potato, cassava (tapioca starch), the pith of the sago palm. The form and size of the starch granules are characteristic of the plant in which it is found. When viewed in the microscope, the grains are seen to be cells made up of an inner nucleus, surrounded by concentric layers. True starch or amylose is present in the interior of the starch cell, while pseudo-starch or amylopectin is contained in the walls of the cell. The formation of starch paste is associated with the presence of the latter substance, which appears to contain a small proportion of combined phosphoric acid.

Starch is obtained by coarsely crushing the raw material, e.g., corn kernels or potatoes, the starch grains are washed free from cellulose and other materials by water. The suspension of starch is allowed to settle and the water drawn off. In the case of corn kernels, the oily germs float on the surface of the suspension and are separated for subsequent extraction of oil. Starch consists of a number of glucose units attached to each other by oxygen linkages to the 3,6 carbon atoms. Starch is an important food material commonly consumed with the **proteins** of cereal grains, rice and potatoes. Starch is a raw material for the brewing industry, for industrial alcohol, for dextrin, and is used in laundering textile goods as a stiffening agent and finish, in sizing paper, and as a thickening agent and adhesive.

Cellulose is a white solid, odorless and tasteless, insoluble in cold or hot water, chemically non-reactive except when drastically treated. Cellulose (1) when heated with water at 260° C. under pressure, dissolves completely with decomposition, (2) when treated with concentrated **sulfuric acid** dissolves, the solution upon dilution and boiling yielding glucose, (3) when treated with **sodium** hydroxide (15% to 25% NaOH) the fibers swell up and upon washing and drying possess a lustrous appearance (mercerized cotton), (4) with **iodine** in **potassium** iodide solution plus **zinc** chloride (Schulze's solution) produces a dark blue color, (5) with 80% **sulfuric acid** and rapidly washed and dried yields parchment surface. Simple cellulose is represented in nature by the cottonseed hair. Compound celluloses are widely distributed in plants, the two principal types being:

(a) Lignocelluloses, of woods, cereal straws, jute. These cellulose materials yield lignin by treatment (1) with 43% **hydrochloric acid,** cold for 12 hours, (2) with 8% to 12% sodium hydroxide at 140° to 160° C. for 6 to 10 hours, (3) with 72% sulfuric acid at ordinary temperature for 18 hours (the common method). Wood yields about 25% of lignin by the last treatment. The composition of lignin is not known.

(b) Pectocelluloses, of flax, hemp, ramie. These cellulose materials yield pectic substances by treatment with oxalic acid or ammonium oxalate at 85° C. for 24 hours, followed by carefully defined treatment with **alcohol, acetic acid** and **calcium** chloride. Pectic substances are most abundant in leaves, e.g., ivy, sycamore, and in apples or oranges, especially the white peel of the latter.

Cellulose of cotton fiber is supplemented industrially by that made from wood of **coniferous** trees, e.g., spruce, hemlock, into pulp, mainly for paper, by treatment (1) with **calcium** hydrogen sulfite plus sulfurous acid solution—the sulfite process—heated under pressure for several hours, (2) with **sodium** hydroxide solution—the soda process—under similar conditions, (3) with **sodium** sulfide plus **sodium** hydroxide solution—the sulfate process—under similar conditions. Other industrial sources of cellulose are flax, hemp, ramie, jute, Manila hemp, cereal straw, used mainly for textiles, and cordage.

Cotton cellulose is an important textile fiber. Cotton and wood cellulose may be transformed into esters, three of which are of outstanding importance. (1) Cellulose nitrates (see Fig. 1), for explosives, plastics, photo-

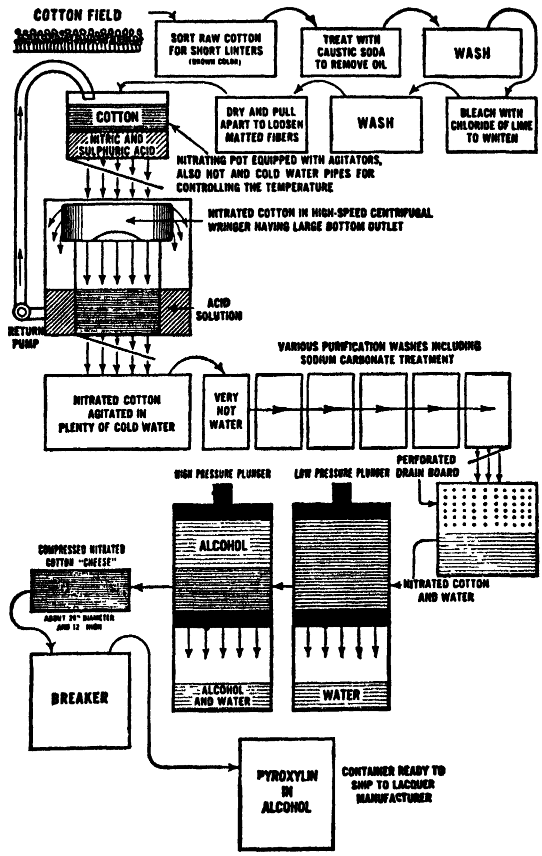


Fig. 1. Flow sheet of nitrocellulose or pyroxlin manufacture from cotton and nitric-sulfuric acid mixture.

graphic films, lacquers, collodion, rayon (made non-inflammable by denitrifying with ammonium sulfide solution), (2) cellulose acetate, for plastics, photographic films, rayon, lacquers, (3) cellulose xanthate, used in making synthetic textile fiber or translucent wrapping paper called viscose. Viscose is made by impregnation of cellulose with sodium hydroxide (17.5% NaOH) solution, sodium cellulose ($C_6H_{10}O_5 \cdot 2NaOH$) approximately being formed (see Fig. 2). Addition of **carbon disulfide** (one mol CS_2 to one mol $C_6H_{10}O_5$, approximately) results in the formation of yellow sodium xanthate (possibly $C_6H_9(ONa) \cdot O \cdot CS \cdot SNa$), which after ripening and purifying is exuded as fibers or sheets into a bath consisting of dilute sulfuric acid plus sodium hydrogen sulfate plus sugar (many recipes for bath liquor are known) at 30° C. The precipitated material is desulfurized by treatment with very dilute **sodium** sulfide solution at 40° to 50° C., or by exposure to air, leaving the fiber or sheet as translucent cellulose. Mixed

with metallic dust and coloring matter, viscose is made into artificial leather.

Cellulose, when treated with ammonio-cupric hydroxide solution (Schweitzer's solution), dissolves, and, when

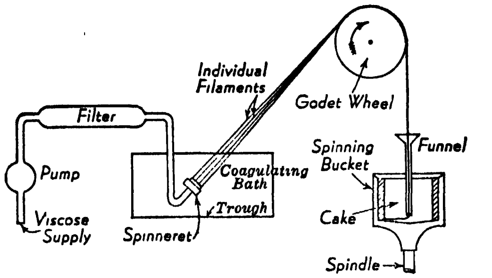

Fig. 2. Diagram showing the formation of rayon filaments and thread. (*duPont Rayon Co.*)

the resulting solution is acidified, translucent flocculent cellulose is precipitated. By exuding the ammonio-cupric cellulose solution through fine orifices into a bath of acid artificial fibers of cellulose are produced—cupra-ammonium process.

Ground wood pulp or paper turns yellow on exposure to sunlight, and with phloroglucinol dissolved in alcohol produces a red color. Lignin complexes of wood are destroyed by treatment with **chlorine** or **bromine** at ordinary temperatures, leaving cellulose residue. Ground wood pulp is bleached by sodium peroxide. Wood powder ("sawdust") when heated at 220° C. with sodium hydroxide plus potassium hydroxide yields sodium potassium oxalate, from which oxalic acid may be obtained. Destructive distillation of wood yields gases, watery distillate—containing **acetic acid,** methyl **alcohol, acetone,** tar distillate and charcoal residue.

Dextrin is a white to yellow solid, forming an adhesive with water, non-reactive with ammonio-cupric salt solution, reactive with iodine in alcohol or potassium iodide, usually forming red, brown, or blue color. Formed when starch is (1) heated to 120° to 200° C. either alone or in the presence of a slight amount of nitric acid. Dextrin is formed when bread is toasted and is present in well-baked bread crust, and on the surface of starched goods that have been ironed hot. Dextrin is used in adhesives.

Inulin is a white solid, soluble in warm water, specific rotatory power —40°, with iodine in alcohol or potassium iodide gives yellow color. Inulin is present in tubers of dahlia to the extent of about 10%. Inulin reacts with water in the presence of the enzyme inulase or of acids to form fructose. The enzyme diastase does not produce this change.

Glycogen, or animal starch, is a white solid, soluble in water, specific rotatory power +197°, with iodine in alcohol or potassium iodide solution, forming brown color. Glycogen is found as reserve carbohydrates in the animal body, more particularly in the liver. Horseflesh, oysters and beef are sources of glycogen.

Pentosans are polysaccharides which may be considered as anhydrides of pentose sugars, after the manner of the hexosans, sucrose, starch, from glucose, fructose. When pentosans or pentoses are heated with hydrochloric or sulfuric acid, furfural ($C_4H_3O \cdot CHO$) is formed, and addition of aniline produces a red color. Pentosans are present in gummy carbohydrates, in bran of wheat seed, and in woods.

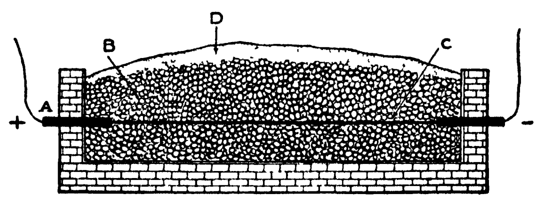
By means of the cyanhydrin reaction higher sugars of the heptose, octose and nonose types have been prepared. A monosaccharide such as an aldohexose may be converted into the next lower monosaccharide, such as an aldopentose, by oxidation to the acid, which corresponds to the aldohexose, then treating the calcium salt solution of this acid with a solution of ferrous acetate plus hydrogen peroxide. Carbon dioxide is evolved and aldopentose formed. (R.K.S.)

CARBON. Symbol: C. Atomic number: 6. Atomic weight: 12.010. Density: (1) Diamond, 3.52, (2) Graphite, 2.25, (3) Amorphous, 1.88. Hardness: (1) Diamond, 10, (2) Graphite, 0.5 to 1.0. Melting point: >3500° C. Boiling point: 4200° C.

The chemical element carbon is known in three forms, namely, (1) diamond, (2) graphite, (3) amorphous, such as charcoal, coke. When heated in excess air or **oxygen,** carbon burns to form carbon dioxide with the evolution of a definite amount of heat from each form. See **Chemical Composition, Allotropic Elements.** Discovery prehistoric. Isotopes: 12 (99.3%), 13 (0.7%). The uses of carbon are dependent upon the form and variety, diamonds for jewels and as abrasive, graphite in lubricants and as an electrical conductor, cocoanut charcoal for adsorbing gases at low temperature in an enclosed space to produce a high vacuum, activated carbon to absorb color from solutions and to remove odor from water, coke and wood charcoal as fuels.

Carbon occurs (1) free, as **diamond** and graphite of local distribution, e.g., diamonds in South Africa, **graphite** in Ceylon, and (2) combined, as carbonate rocks, such as **limestone** and **dolomite,** as **hydrocarbons** in petroleum, natural gas, coal, and as plant and animal constituents generally distributed.

Microscopic diamonds have been made by crystallization of carbon dissolved in iron under high pressure of the solidifying iron. Graphite is made artificially from anthracite coal by heating to the temperature of the electric furnace. Various varieties of carbon are prepared by heating certain organic materials, e.g., cocoanut charcoal for gas adsorption, bone charcoal and activated car-



Graphite production in electric resistance furnace by Acheson process. A, Electrodes of graphite, B, Charge of coarse grains of coke; C, Core of carbon rod; D, Covering of sand and coke mixture.

bon for decolorizing solutions of organic substances, lamp black or soot for paint pigment by incomplete combustion of natural gas or petroleum, gas carbon by coking the residue in the distillation of petroleum, coke and wood charcoal by the destructive distillation of coal and wood, respectively. (See **Destructive Distillation.**)

The behavior of different forms of carbon towards strong oxidizing agents, e.g., **nitric-sulfuric acid** mixture or sulfuric acid plus **potassium** chlorate, serves to distinguish them. Diamond is unacted upon by these reagents, graphite upon prolonged treatment and heating yields graphitic acid, yellow, of the original external form of the graphite, and amorphous carbon forms are dissolved yielding humic acid and finally mellitic acid ($C_6(COOH)_6$), melting point 286° C.

Acids, carboxylic.

Carbides. **Calcium** carbide (CaC_2) and **sodium** carbide (Na_2C_2) yield **acetylene** with water; **aluminum** carbide (Al_4C) yields **methane** with water; **silicon** carbide (SiC) and **titanium** carbide (TiC) do not react with water; silicon carbide and **tungsten** carbide are used in machining operations on account of their hardness (see **Abrasives**); carbides of **iron** (Fe_3C), **manganese** (Mn_3C), and **chromium** (Cr_4C, Cr_3C_2), and many other metals, also of **boron** (B_6C) have been reported.

Chlorides. (See **Chlorine.**)

Hydrides. (See **Hydrocarbons.**)

Oxides. Carbon dioxide, carbonic acid anhydride, "carbonic acid gas" (CO_2) is a colorless gas, density 1.9769 grams per liter, 0° C., 760 mm. or 1.53 when air equals 1.00, melting point —56.6° C. at 5.2 atmospheres, solid

sublimes at —79° C. at 1 atmosphere, critical temperature 31° C., critical pressure 73 atmospheres, soluble about one volume in one volume of water at 15° C. and 1 atmosphere. Carbon dioxide is used in solution under pressure for carbonated beverages, as a liquid for extinguishing fires and making solid carbon dioxide, and as a solid ("carbon dioxide snow," "dry ice") in the maintenance of low temperatures, and as a gas quickly generated, for extinguishing fires and making carbonates, and is the source of carbon (in the atmosphere) for plant life. Carbon dioxide is chemically a remarkably permanent gas, requiring such treatment as burning magnesium to separate carbon (plus magnesium oxide); it is, however, reduced to carbon monoxide at a red heat by carbon or iron; and dissociates into carbon monoxide plus oxygen above 1300° C. (69% unchanged at 2400° C.). Carbon dioxide is formed (1) in the combustion of fuels when burned with excess air, (2) in the respiration of animals by oxidation of foods, (3) by the action of acids on carbonates, (4) by heating carbonates, such as sodium hydrogen carbonate (not sodium carbonate), **calcium** carbonate, or **magnesium** carbonate; and is recovered from (5) **fermentation** processes, and (6) many gas wells. The atmosphere contains about three parts by volume of carbon dioxide in 10,000 volumes of air.

Carbon dioxide is estimated by absorption in **sodium** or **potassium** hydroxide solution and measuring the volume of the gas before and after absorption; by absorption with solid sodium hydroxide or soda-lime and weighing before and after absorption; or by passage through **barium** hydroxide solution and titration of the alkali before and after passage. During rest, the human body maintains a constant pressure of carbon dioxide in the lungs (5.6% CO_2), a rise in the percentage of carbon dioxide increases the rate of breathing (even 0.2% increase in carbon dioxide doubles the rate of breathing), and a fall in the percentage decreases the rate of breathing with danger of cessation.

Carbon monoxide, carbonic oxide (CO) is a colorless, odorless gas, density 1.2504 grams per liter, 0° C., 760 mm. or 0.98 when air equals 1.00. Melting point —207° C., boiling point —192° C., insoluble. Carbon monoxide has marked physiological effect through its combination with the blood, probably forming purple carboxyhemoglobin more stable than oxyhemoglobin which oxygen forms, thus poisoning by oxygen starvation of the blood. Its presence in blood may be recognized by the characteristic absorption spectrum and the behavior of the spectrum with certain chemicals. Poisoning by inhalation of carbon monoxide, which is odorless, is a serious hazard where there are present exhaust gases from internal combustion engines or gases from the incomplete combustion of fuels from stoves and furnaces. (See **Carbon Monoxide Poisoning.**) Chemically, carbon monoxide is (1) combustible to form carbon dioxide, accompanied by a transparent blue flame and the evolution of heat, but the fuel value is low (320 B.T.U. per cu. ft.) (2) reactive with **chlorine,** forming carbonyl chloride ($COCl_2$) in the presence of light and a **catalyzer,** (3) reactive with **sulfur** vapor at a red heat, forming carbonyl sulfide (COS), (4) reactive with **hydrogen,** forming methyl **alcohol** (CH_3OH) or **methane** (CH_4) in the presence of a catalyzer, (5) reactive with **nickel** (also **iron, cobalt, molybdenum, ruthenium**) to form nickel carbonyl ($Ni(CO)_4$) (and carbonyls of the other metals named), (6) reactive with fused **sodium** hydroxide, forming sodium formate (HCOONa), (7) reactive with **cuprous** salt dissolved in either **ammonium** hydroxide or concentrated **hydrochloric acid,** which solutions are utilized in the estimation of carbon monoxide in mixtures of gases, e.g., flue gases of combustion, coal gas, exhaust gases of internal combustion engines, (8) reactive with **iodine** pentoxide at

150° C. For the reaction of carbon monoxide with oxygen to form carbon dioxide—finely divided **iron**, or **palladium** wire is a catalyzer; for the reaction of carbon monoxide with water vapor to form carbon dioxide plus hydrogen ("water gas reaction") important studies have been made of the conditions; and for the reaction of carbon dioxide plus carbon heated similar important studies have been made (at 675° C., 50% CO_2 plus 50% CO; at 900° C., 5% CO_2 plus 95% CO). Carbon monoxide is formed by the incomplete combustion of **fuels**. The reaction of carbon plus oxygen at such a temperature as produces carbon monoxide (say 900° C., 95% CO plus 5% CO_2) evolves heat, while the reaction of carbon plus carbon dioxide, producing carbon monoxide at the same temperature absorbs heat. Accordingly, it is possible to arrange the oxygen (free or as air) and carbon dioxide supply ratio in such a way that the desired temperature may be continuously maintained. The reduction of carbon dioxide by iron forms carbon monoxide plus ferrous oxide.

Carbon suboxide (C_3O_2) is a colorless gas, of unpleasant odor, poisonous, boiling point 7° C., burns with a blue smoky flame producing carbon dioxide. When condensed to liquid, carbon suboxide slowly changes at ordinary temperature to a dark red solid, soluble in water to a red solution. Reacts with water to form malonic acid, with **hydrogen chloride** to form malonyl chloride, with **ammonia** to form manolamide. Made by heating malonic acid or its ester at 300° C. under diminished pressure, and separation from simultaneously formed carbon dioxide and ethylene by condensation and fractional distillation.

Compounds of carbon are discussed as follows:

Antimony-containing. (See **Antimony, organic compounds.**)
Arsenic-containing. (See **Arsenic, organic compounds.**)
Boron-containing. (See **Boron, organic compounds.**)
Bromine-containing. (See **Bromine, organic compounds.**)
Chlorine-containing. (See **Chlorine, organic compounds.**)
Fluorine-containing. (See **Fluorine, organic compounds.**)
Halogen-containing. (See **Individual Halogen.**)
Hydrocarbons.
Iodine-containing. (See **Iodine, organic compounds.**)
Metal-containing. (See **Individual Metal.**)
Nitrogen-containing. (See **Nitrogen, organic compounds**, but first consult key below)
Oxygen-containing. (See **Oxygen, organic compounds**, but first consult key below.)
Phosphorus-containing. (See **Phosphorus, organic compounds.**)
Silicon-containing. (See **Silicon, organic compounds.**)
Sulfur-containing. (See **Sulfur, organic compounds.**)

Organic compounds are discussed as follows:

Sulfur-containing organic compounds are listed under **Sulfur.**

Phosphorus-containing organic compounds are listed under **Phosphorus.**

Chlorine-containing organic compounds are listed under **Chlorine.**

Bromine-containing organic compounds are listed under **Bromine.**

Iodine-containing organic compounds are listed under **Iodine.**

Fluorine-containing organic compounds are listed under **Fluorine.**

Nitrogen-containing organic compounds are listed under **Nitrogen.**

Organic compounds containing carbon and hydrogen only are listed under **Hydrocarbons.**

Organic compounds containing carbon and oxygen only are listed under **Carbon, oxides.**

Organic acids containing carbon, hydrogen and oxygen only are listed under **Acids, carboxylic.**

Organic compounds containing oxygen, *except those cited above,* are listed under **Oxygen.**

Organic compounds are grouped as follows:

Division Number	Chemical Elements	Generic Groups	
I	C, H	Hydrocarbons	See **Hydrocarbons**

CARBON SCHEME SHOWING TYPES OF CARBON ARRANGEMENTS.

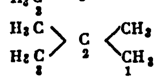
A. Carbon Chain Compounds

(1) Straight chain

$H_3C—CH_2—CH_3$ Propane (C_3H_8)

(2) Forked or branched chain

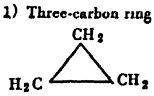
Trimethylmethane (C_4H_{10}) (2-Methylpropane)



Tetramethylmethane (C_4H_{10}) (2,2-Dimethylpropane)

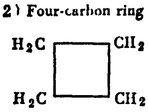
B. Carbon Ring Compounds Carbocyclic

(1) Three-carbon ring



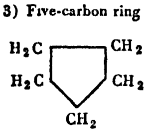
Cyclopropane (C_3H_6)

(2) Four-carbon ring



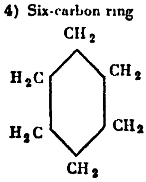
Cyclobutane (C_4H_8)

(3) Five-carbon ring

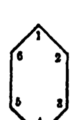


Cyclopentane (C_5H_{10})

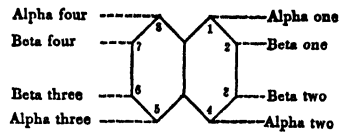
(4) Six-carbon ring



Cyclohexane (C_6H_{12})

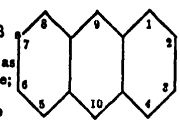


Benzene (C_6H_6)

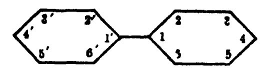


Naphthalene ($C_{10}H_8$)

Positions 1 to 8 are named alpha and beta as for naphthalene; 9, gamma one 10, gamma two



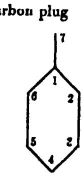
Anthracene ($C_{14}H_{10}$)



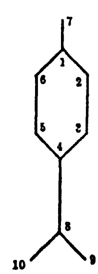
Diphenyl ($C_{12}H_{10}$)

C. Combinations of Carbon Chain and Carbon Ring

(1) Six-carbon plug

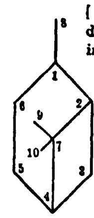


Carbon skeleton of toluene (C_7H_8 on $C_6H_5 \cdot CH_3$)



Carbon skeleton of limonene ($C_{10}H_{16}$), a terpene hydrocarbon

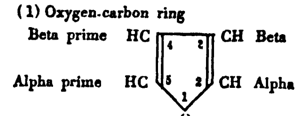
(2) Bridged ring (3 bridges from No. 2 to No. 4, (1) via No. 3, (2) via No.7, (3) via No. 1,6,5. Therefore, "bicyclo [3.1.1] heptane" Numbers inside the square brackets denoting the number of carbons in each bridge - not counting the piers (No. 2,4)



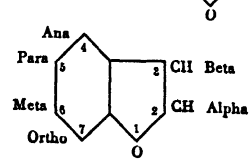
Carbon skeleton of pinene ($C_{10}H_{16}$), a terpene hydrocarbon

D. Heterocyclic Compounds

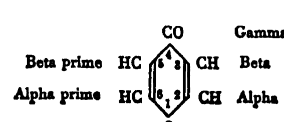
(1) Oxygen-carbon ring



Furane (C_4H_4O)

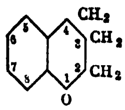


Coumarone (C_8H_6O)



Gamma-pyrone ($C_5H_4O:O$)

5-8, as for 4-7, respectively of coumarone



2 to 4, alpha, beta, and gamma as of pyrone

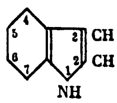
Chromane ($C_9H_{10}O$)

(2) Nitrogen-carbon ring

2 to 5, alpha and beta, as of furane

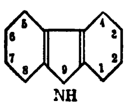
Pyrrole (C_4H_5N)

4-7, as of coumarone



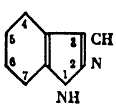
2 to 3, alpha and beta, as of coumarone

Indole (C_8H_7N)

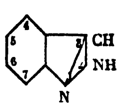


Carbazole ($C_{12}H_9N$)

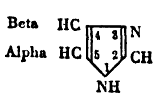
Pyrazole ($C_3H_4N_2$)



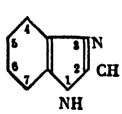
Isindazole ($C_7H_6N_2$)



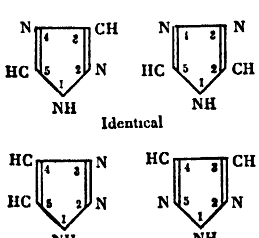
Indazole ($C_7H_6N_2$)



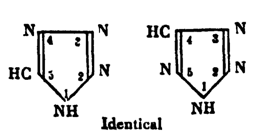
Iminazole ($C_3H_4N_2$)



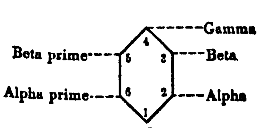
Benziminazole ($C_7H_6N_2$)



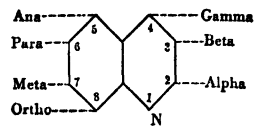
Triazoles ($C_2H_3N_3$)



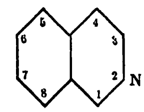
Tetrazole (CH_2N_4)



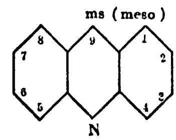
Pyridine (C_5H_5N)



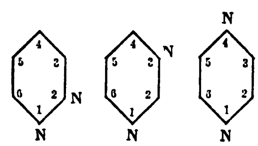
Quinoline (C_9H_7N)



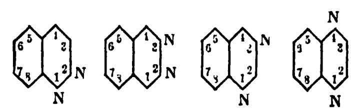
Isoquinoline (C_9H_7N)



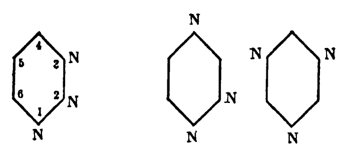
Acridine ($C_{13}H_9N$)



Three diazines ($C_4H_4N_2$)
1. 1,2 (pyridazine)
2. 1,3 (pyrimidine)
3. 1,4 (pyrazine)

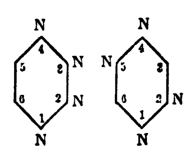


Four benzodiazines
1. 1,2 (cinnoline)
2. 2,3 (phthalazine)
3. 1,3 (quinazoline)
4. 1,4 (quinoxaline)



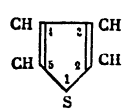
Vicinal Asymmetrical Symmetrical

Three triazines
1. 1,2,3
2. 1,2,4
3. 1,3,5 (cyanidine)



Two tetrazines
1. 1,2,3,4
2. 1,2,4,5

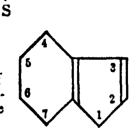
(3) Sulfur-carbon ring



2 to 5, alpha and beta, as of furane

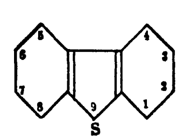
Thiophene (C_4H_4S)

4-7 as of coumarone



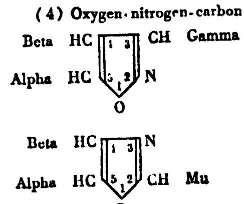
2 and 3, alpha and beta, as of coumarone

Thionaphthene (C_8H_6S)



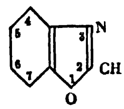
Diphenylene sulfide ($C_{12}H_8S$)

(4) Oxygen-nitrogen-carbon ring

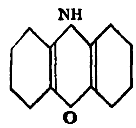


Two oxazoles (C_3H_3NO)
1. 1-O-2-N
2. 1-O-3-N

CARBON SCHEME SHOWING TYPES OF CARBON ARRANGEMENTS.—*Continued.*

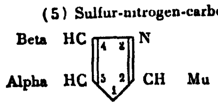


Benzoxazole (C_7H_5NO)

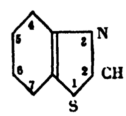


Phenoxazine ($C_{12}H_9NO$)

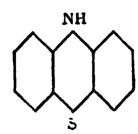
(5) Sulfur-nitrogen-carbon ring



Thiazole (C_3H_3NS)



Benzthiazole (C_7H_5NS)



Phenthiazine ($C_{12}H_9NS$)

(R.K.S.)

CARBON DIOXIDE. Carbon, Oxides.

CARBON MONOXIDE POISONING. Carbon monoxide (which is discussed under **Carbon**) is a colorless and odorless gas, produced when carboniferous materials are burned without sufficient oxygen for complete **combustion.** In this mechanical age it is probably the most widely distributed of toxic agents. It is not known how many deaths are due to this agent, but the number is great. In various industries, as in the manufacture of steel, mining of coal, the burning of gas and coal, carbon monoxide gas is produced in great quantities. The greatest source of this poison, in general, is from the exhaust of motor cars, where its concentration is 7%. From this source alone many thousands of persons are to some degree affected daily.

Carbon monoxide kills because it combines with the haemoglobin of the blood, thus making it impossible for the haemoglobin to combine with oxygen, which is a necessary life process. Carbon monoxide has an affinity for haemoglobin 300 times that of oxygen. The degree of poisoning depends on concentration of the gas and time of exposure. If the percentage of the gas in the blood rises to 70% or 80% death is likely to ensue. After death the blood is a bright cherry-red and hemorrhages and **edema** of the brain are found.

A chronic form of poisoning is believed to result in headaches, palpitation, dizziness, anemia, psychoses, and neuritis.

The treatment of acute poisoning is immediate artificial respiration, and, as soon as obtainable, the inhalation of a mixture of 95% oxygen and 5% carbon dioxide. The carbon dioxide is a direct respiratory stimulant and the pure oxygen hastens the release of carbon monoxide from the haemoglobin. Even after recovery, delayed secondary complications such as paralysis and cerebral hemorrhage may occur. (R.S.M., D.M.H.)

CARBONADO (BLACK DIAMOND). The mineral carbonado is an opaque massive black variety of diamond, often crystalline to granular or compact and without cleavage. In thin splinters it appears greenish-black by transmitted light. It is found chiefly in Bahia, Brazil. Carbonado is in demand for rock-drilling apparatus. (E.S.C.S.)

CARBONATE. Carbonic Acid.

CARBONIC ACID AND CARBONATES. Carbonic acid (H_2CO_3) is a solution formed when **carbon dioxide** is dissolved in water. The concentration of acid formed is small, and carbon dioxide may be completely expelled upon boiling. The solution reacts with alkalis to form carbonates, e.g., sodium carbonate, sodium hydrogen carbonate, calcium carbonate, calcium hydrogen carbonate.

Metallic carbonates are (1) soluble, e.g., **sodium** carbonate, **potassium** carbonate, **ammonium** carbonate, (2) insoluble, e.g., **calcium** carbonate, **strontium** carbonate, **barium** carbonate, **magnesium** carbonate, **ferrous** carbonate, **silver** carbonate. Metallic bicarbonates are known in solution and on warming are converted into ordinary or normal carbonates, e.g., bicarbonates of sodium, potassium, calcium, barium. Basic carbonates are important in such cases as lead ("white lead"), **zinc, magnesium, copper.** Carbonates of very weak bases, such as **aluminum, ferric,** and **chromic** are not known. Found in nature as the carbonates, **calcite, Iceland spar, limestone** and various forms of impure calcium carbonate ($CaCO_3$), as **magnesite (magnesium** carbonate, $MgCO_3$), as dolomite (various compositions of calcium and magnesium carbonates), as **witherite** ($SrCO_3$), as **strontianite** ($SrCO_3$), as **azurite** and **malachite** (various compositions of cupric hydroxycarbonates), in various natural waters as carbonic acid, calcium and magnesium hydrogen carbonates, in blood, as sodium hydrogen carbonate. Esters of carbonic acid are: diethyl carbonate, ethyl ester of meta-carbonic acid, boiling point 126° C. ($(C_2H_5O)_2CO$), made by reaction of ethyl alcohol and carbonyl chloride; dimethyl carbonate ($(CH_3O)_2CO$), boiling point 90° C.; methylethyl carbonate ($(CH_3O)CO(OC_2H_5)$), boiling point 109° C; dipropyl carbonate ($(C_3H_7O)_2CO$), boiling point 168° C.; tetraethyl carbonate, ethyl ester of orthocarbonic acid ($(C_2H_5O)_4C$), boiling point 158° C., made by reaction of sodium ethylate and chloropicrin (CCl_3NO_2). Urethanes, ureas, guanidines are carbonic acid derivatives. Carbonates may be detected by the fact that dilute sulfuric acid liberates carbon dioxide from the solid. The carbon dioxide produces a white precipitate with barium hydroxide. The carbon dioxide does not decolorize iodine solutions as sulfur dioxide does. (See **Amines and Amides.**) (R.K.S.)

CARBONIFEROUS PERIOD. Mississippian and Pennsylvania.

CARBONYL. Radicals.

CARBOXYL. Radicals.

CARBOXYLIC ACID. Acid, Carboxylic.

CARBRO COLOR PRINTING. A subtractive-color printing process that has been widely used for making color photographs. Three pigment images of the proper colorants are prepared following the general procedures employed in making a monochrome carbro except that several transfers of the images from one support to another are necessary, using selected pigments for 3-color reproduction.

Suitable bromide prints are prepared from each of the separation negatives and then each is contacted, gelatin surfaces together, with the suitably colored pigment paper which has been previously soaked in the sensitizing solution. Sensitizing solutions vary widely but gener-

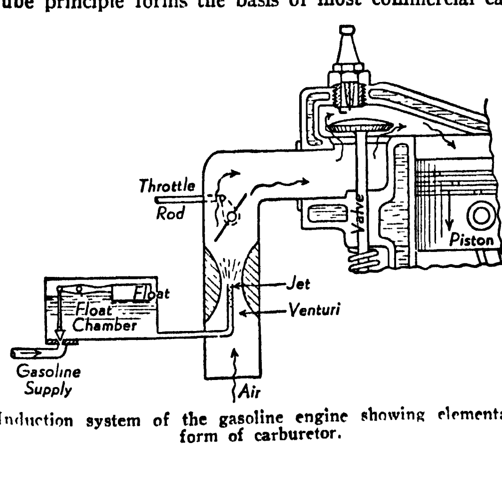
ally contain an acid chromate, ferricyanide and bromide. The combining of the pigment papers with the appropriate bromide prints is generally carried out in a roller wringer. After the silver in the bromide prints is bleached, the pigments are squeegeed onto waxed celluloid or other suitable supports so that the paper backing and soluble gelatin-bearing pigment may be removed in hot water leaving on each celluloid a positive colorant image of pigmented gelatin. These images are dried, then resoaked and contacted, one at a time, with paper which has a clear gelatin coating soluble at a relatively low temperature. When the 3-colorant pigment images are superimposed, they are resoaked in water and placed in contact with the final support which may be almost any hardened gelatin surface. When they have partially dried together the temporary support paper is stripped off in hot water leaving the color print on its final support. (H.C.C.)

CARBUNCLE. In geology this term is applied to that variety of **garnet, almandine,** which was much used formerly for jewelry, when cut en cabochon. It is derived from the Latin, *carbunculus,* a small spark, in reference to the glowing effect of that style of cutting. In the early part of the Christian Era, the term seems to have been used for red stones of all sorts.

In medicine, a carbuncle is a severe localized infection, usually occurring in the **subcutaneous** tissues. It starts in the same way as a boil, but then spreads down to the subcutaneous tissues where it may form a diffuse lesion discharging to the surface by several—instead of one—openings. It is a more serious infection than a boil and a longer time is required for it to subside. Fever and constitutional symptoms are frequently marked and in some instances death may result from **septicemia.** The causative organism is usually a **staphylococcus** *aureus.* Treatment is surgical incision and chemotherapy with one of the **sulfonamides** or **penicillin,** if necessary. (E.S.C.S., R.S.M., D.M.H.)

CARBURETION. The fuel for an **internal combustion engine** must be thoroughly mixed with the air needed for combustion. This is very true of the **Otto cycle** engine, since thorough distribution of particles of fuel in the air is essential to the rapid and complete explosive combustion of the fuel in that cycle. One of the most effective means of mixing the particles of a liquid fuel with air is by vaporization. The vaporizing and mixing of a liquid fuel with air in the correct proportions is called carburetion, and the device to accomplish this, a carburetor.

The automobile engine offers an instance of applied carburetion, also one of the more difficult carburetive problems, since the automobile engine is expected to operate smoothly and economically with wide variation of power, using fuels of varying quality. **The Venturi tube** principle forms the basis of most commercial carburetors. In its simplest form it consists of a Venturi tube in the passage leading from the atmosphere to the cylinder. As the air passes this tube, it is speeded up at the throat due to the constriction in flow area, and the static pressure of the air is reduced. A gasoline chamber with a gasoline level which is maintained slightly below that of the level of the throat of the Venturi, supplies gasoline through an interconnecting tube to a jet whose opening is located in the area of reduced pressure at the Venturi throat. Since the surface of the gasoline in the float chamber is subject to atmospheric pressure the pressure difference causing gasoline to be sprayed out of the jet is the same as that which exists between the atmosphere and the throat of the Venturi tube. Thus both air and gasoline are subjected to the same driving pressure, and when one increases the other increases, and vice versa. If the discharge of gasoline from the jet, and of air through the Venturi increased in the same ratio, this simple carburetor would be successful for automotive service, but unfortunately the rate of increase of gasoline flow with increasing pressure difference exceeds that for air.



Induction system of the gasoline engine showing elementary form of carburetor.

The mixture delivered by this carburetor is given by the following equation, in pounds of air per pound of gasoline:

$$\text{Mixture} = \frac{C_a A_a}{C_g A_g}\sqrt{\frac{d_a}{d_g}}.$$

C's are coefficients of discharge.
A's are areas of flow.
d's are densities of the fluids.

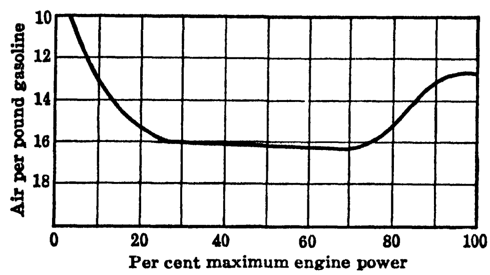
With ordinary gasoline this mixture should be maintained at a theoretical 15.2 lbs. of air per lb. of gasoline. The simple Venturi tube carburetor will not do that, but rather will give an increasingly richer mixture, as the velocity of air through the Venturi increases. The principal reason for this characteristic will be found in the variability of the coefficients of discharge. The coefficient of discharge for air through a Venturi tube is approximately constant, but that of gasoline from a jet increases with increasing pressure differential across the jet.

The commercial Venturi-type carburetor contains modifications which offset this basic undesirable characteristic so that a suitable mixture will be maintained at all loads. The simplest method employed to oppose enrichment of mixture was to provide an auxiliary valve admitting air to the mixture before it reached the cylinder. This auxiliary air valve opening was closed by a spring-loaded valve which was held partially open by the suction in the manifold, and admitted fresh air to dilute the overrich mixture. The carburetion obtained by the auxiliary air valve principle was inferior to other methods, and has been abandoned.

If the gasoline supply tube is constricted between the float chamber and the jet, the pressure drop across the constriction will increase at increasing rates of flow, and the result will be a tendency for starvation of the jet, and weakening of the mixture at high air velocities. By combining properly a jet of this type with one of the unrestricted type, a compound jet arrangement may be designed which will give fairly uniform mixture at varying loads. The use of a restricted jet, together with extra high speed jets that come into play when the air speed through the Venturi exceeds a certain value, is another modification of the simple Venturi carburetor. Some carburetors have a variable orifice on the gasoline jet created by the use of a throttle-operated metering pin; others have a Venturi tube with variable opening.

In one type of carburetor the density of the gasoline issuing from the jet is, in effect, varied by bleeding air bubbles into the vertical stem of the jet in such a way that the amount of air mixed with the gasoline increases with increasing load, thus tending to offset the enriching tendency of a plain Venturi jet carburetor. This air bleeding of the jet is called the plain-tube principle of carburetion.

Although a mixture of 15.2 lbs. of air per lb. gasoline is theoretically correct, mixtures as rich as 9:1 or as lean as 20:1 are explosive. However, the rich mixtures are uneconomical, and the lean mixtures must be employed cautiously at maximum power to prevent **detonation** and overheating. Thus rich mixtures are indicated near full power operation. Also, on account of the proportionately high dilution of incoming fuel stream by unscavenged products of combustion at the previous cycle at light loads (under quantity control), a rich mixture is needed at low power output. Between these needs for rich mixture, the carburetor should deliver a fairly uniform lean mixture for the sake of fuel economy. The accompanying graph illustrates a desirable performance for the carburetor of a gasoline engine. By employing



Desirable carburetor performance.

multiple jets, adjustable orifices and other intricacies, commercial carburetors attain mixture control approximating this desired performance, at considerable sacrifice of the simplicity of the principle of Venturi tube metering. (F.T.M.)

CARBURETION, AIRCRAFT ENGINE. Carburetor Types.

CARBURETOR TYPES. A carburetor is any device for securing the **carburetion** function described in the article of that name. It is a necessary device for any engine, furnace, kiln, etc., where a volatile liquid fuel is prepared for combustion by vaporizing into the flow of combustion air. The possibility of accomplishing carburetion satisfactorily in many different ways is attested by the great variety of commercial carburetors in use. The types vary from simple to extremely complicated, depending upon the degree to which the following requirements are present, and the perfection with which they must be met:

1. Variable power over a range from idling to maximum horsepower at full rated speed.
2. Speed variations ranging from nearly constant speed under governor control to speed controllable from idling speed to a maximum speed of several thousand revolutions per minute. Rapid acceleration at varying rates may also be an imposed requirement.
3. Desired thermal efficiency, which may vary from a factor of little importance for some types of engines to one of major importance in others.
4. Required operation when idling may vary from rough and irregular to perfectly smooth.
5. Requirements imposed by the mobility of the engine. If stationary, there is no trouble with surge of fuel in supply chambers. Some engines, as on automobiles, have the carburetors subject to moderate accelerations, but remaining in approximately level position. Aircraft engine carburetors are subject to great accelerations, and those which are employed on acrobatic or combat aircraft may be required to operate in all possible physical positions.
6. The fuels to be carbureted may be of varying volatility.

Most carburetors expect to secure vaporization by the use of a low-pressure spray of fuel (gasoline) into a rapidly moving stream of air from a stationary jet. The purpose of the spray is to expose a large surface of the volatile gasoline for auto-evaporation. As the heat evaporated must come mainly from the fluids themselves, the carbureted mixture undergoes a cooling of several degrees. This is helpful in improving **volumetric efficiency,** although promoting, under some conditions, formation of ice in the body of the carburetor. Other carburetors employ a moderate pressure spray and are adaptable to less volatile fuels than gasoline. Still other carburetors have been devised which, instead of a spray, expose a liquid surface in a pool over which is swept the air which it is desired to carburet. Such have been called puddle carburetors, but are deemed to be suitable to meet the requirements mentioned in the preceding paragraph only in the most limited fashion.

A comprehensive and understanding survey of carbureter types may well revert, for background, to the equation for the air-fuel mixture supplied by a simple, low-pressure jet, Venturi carburetor. The equation, as set forth in **carburetion,** shows a "coefficient of discharge" ratio C_aC_g multiplying orifice area of the gasoline and air flow, and densities of the air and gasoline. When a simple Venturi carburetor is operated at increasing rates of air flow through it, the numerical magnitude of the coefficient ratio tends, by natural phenomena, to decrease, thus increasing the richness of the mixture. To offset this, and obtain approximately uniform mixture under variable air flow, A_a might be increased, or A_g might be decreased. There can be little control over the density of the air, but the effective density leaving the gasoline jet is controlled in some types of carburetors by mixing it with variable quantities of air bubbles. Now these three possibilities have all been employed in carburetors. The "variable Venturi" carburetor in effect varies the area of the air orifice. The "metering pin" carburetor is arranged to produce a variable gasoline discharge orifice. The "restricted air bled jet" produces an effect analogous to a change of density of the gasoline. Other compensating principles employed in carburetors involve ingenious uses of extra jets to supplement the main jet, while others have been designed with auxiliary air valves arranged to admit air to the over-rich carbureted mixture, and so dilute it approximately to the desired richness.

The principal parts of a carburetor might be functionally classified as:

1. A device to meter the fuel into variable air flow to obtain the desired fuel-air ratio.
2. A regulated pressure supply of fuel to the metering equipment.
3. A means for varying the flow of the air-fuel mixture to meet variable demand for power.
4. Auxiliary device to provide the additional perfection of smooth idling, temporary richness for acceleration, and mixture adjustment to compensate for variable air density occurring during large variations in altitude (aircraft carburetors).

Most carburetors use either the "butterfly" valve shown in Fig. 1, or a variable Venturi (Fig. 1*A*) to impose a controlled variable pressure drop between the carburetor and cylinders for the purpose of controlling power or speed. For the purpose of securing a super-rich mixture while cranking the engine at low speed preparatory to starting, the air entrance into the carburetor is almost completely closed by the operation of a valve similar to the butterfly, which is called a "choke." This imposes a high vacuum internally in the carburetor, and assists in drawing large quantities of gasoline violently from the jet. This is needed during starting, because of the quantity of condensation on the cold manifold and the poor vaporization occurring during starting.

The task of metering gasoline into the air precisely is a difficult one, at best, and for its success, the metering equipment must be supplied with the gasoline under con-

stant head or pressure. Between the original source, such as a gasoline supply tank, and the jets, there must be imposed a means for regulating the gasoline supply to the metering devices. Many carburetors use a float-controlled valve arranged to maintain a steady liquid level in a float chamber. This arrangement is subject, however, to the fault of surge and splash, and disruption of the desired level if the carburetor is not maintained approximately horizontal, or if it is subject to severe acceleration. Float control is quite successful for automobiles, trucks, stationary engines, and many other applications, including even aircraft engines where the required operating conditions are not excessively severe. Where the float control is unsatisfactory, constant pressure supply is possible by using a spring-loaded diaphragm whose motion will control the valve admitting fuel from the source of supply. Both of these methods of regulating the supply chamber are illustrated in Fig. 2. The success of any carburetor depends on how good its metering system is. There has been previous mention of methods of metering. Some of these will be described in more detail by reference to Fig. 3. The auxiliary air valve type displaces a light spring-loaded valve opening into the carburetor body on the discharge side of the Venturi. The simple jet as shown will tend to produce too rich a mixture at the higher air velocities through the carburetor. These high velocities are accompanied by lower pressures in the region around the auxiliary air valve,

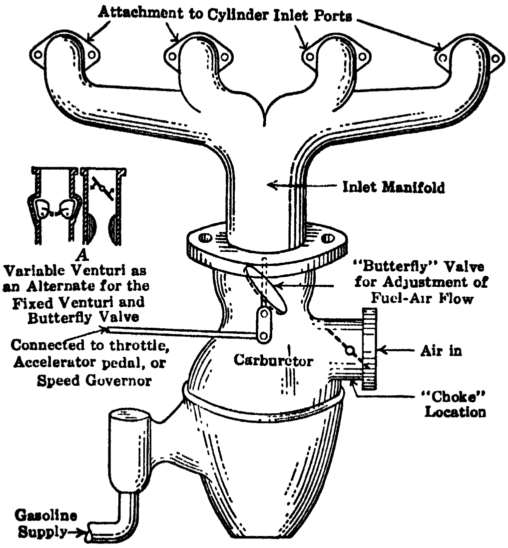


Fig. 1. Elements of the carburetor induction system.

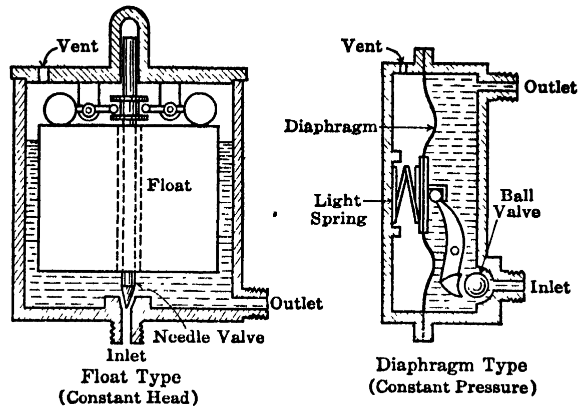

Fig. 2. Methods of regulating gasoline supply to metering devices.

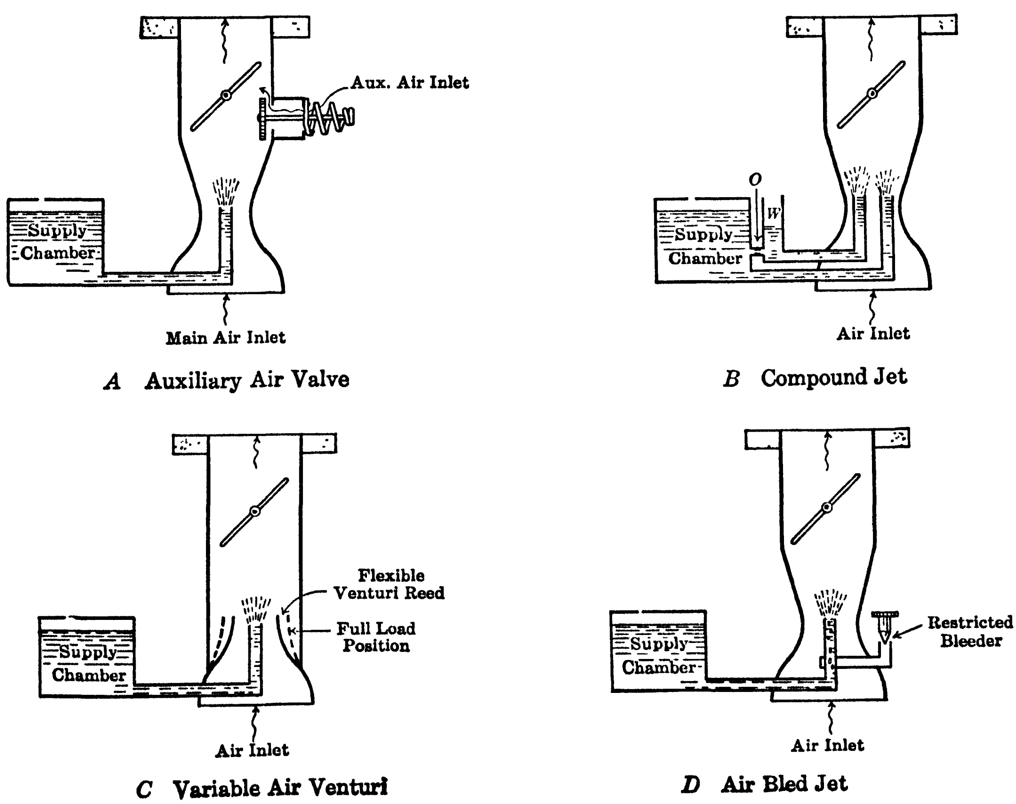

Fig. 3. Methods of metering.

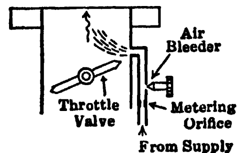
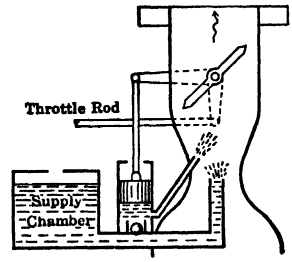
which is thereby induced to open to an extent roughly proportional to the decrease of pressure, admitting uncarbureted air and effecting a dilution of the mixture. The variable Venturi carburetor employs a Venturi section (of somewhat imperfect design) whose sides are built of springy strips, or reeds. At slower air speeds the reeds are nearly closed, producing a high vacuum, and improving the tendency of the jet to spray gasoline. At higher air speeds the reeds open more and provide a larger area through which the air can flow. As there is no increase in gasoline jet area, this action is seen to be in opposition to the normal tendency of a static Venturi carburetor to provide a rich mixture at high speeds. Another (illustrated in Fig. 3) is the compound jet, sometimes referred to as the unrestricted air bled jet. Two jets are shown, a main jet *M*, and an auxiliary jet *A*. The main jet is a plain jet, and will tend to give an increasingly rich mixture as air flow increases through the Venturi. However, the size of the main jet is not sufficient to produce enough gasoline properly to charge the air moving through the vent, and needs the action of the auxiliary jet to provide the difference. This auxiliary jet has an inverted characteristic, that is, it tends to give an increasingly lean mixture as the air flow increases. By a suitable combination of the areas of the two jets with the area of the Venturi, an approximately uniform mixture may be maintained over a range of air speed. The inverted characteristic is secured by feeding jet *A* from a well *W* which receives gasoline from the supply chamber through an orifice *O*. The higher the rate of gasoline flow through *A*, the more of the available driving pressure there will be consumed by the orifice *O*. Consequently, the discharge of gasoline from jet *A* will not increase proportionately faster than the air speed, as is the case with *M*, but will even fail to keep pace with the air flow. Thus, at low air speeds, the gasoline level in *W* will be nearly up to the constant level of the supply chamber, but will lower as air speed increases, and finally, at maximum speeds, will uncover the orifice, and air will then mix with the gasoline going to the jet, greatly reducing its delivery, and thus compensating for the increase of the main jet.

A jet modifying action of considerable success is illustrated by the air bled jet of Fig. 3. This might be termed a restricted air bled jet, and its principle of operation is as follows. A plain jet, opening into the throat of the Venturi, has a side entrance brought into it somewhere near the tip of the jet through which air may inflow, when the throat pressure is reduced below atmospheric, thus providing a mixture of air bubbles and gasoline in the ascending flow to the jet. Space occupied by the air bubbles cannot, of course, be occupied by the gasoline also, and hence the effect of the air bleeding is to choke the quantity of gasoline that can be discharged from the jet. As the air velocity through the vent increases, and the pressure driving the gasoline from the supply chamber up the jet thereby is increased, the induction effect of the air through the bleeder is likewise increased. Suitable proportioning of the gasoline jet to the Venturi orifice, coupled with an adjustment of the air bleeder, has been found to effect very good control on the mixture over a wide range of air flow.

These principles have been diagrammed in a very elementary way, and without reference to any particular manufacturer's practice. None of these metering principles can effect precisely the desired performance as set forth graphically in the article on **carburetion** unless they are assisted by other means such as special auxiliary jets, orifices, wells, and the like. To examine in detail these various modifications is beyond our present scope; however, the principles of two common auxiliaries are pictured in Fig. 4. When idling at very low engine speeds, the throttle valve of an engine is nearly closed, and the flow of air through the Venturi is so slow that no adequate or reliable jetting pressure may be expected. An idling jet is led to an outlet point on the cylinder side of the closed throttle valve, where the suction vacuums are high. The suction will draw up gasoline from the supply to this jet, and a mixture for smooth



Idling Jet



Acceleration Jet

Fig. 4.

idling may be obtained by adjusting air bleed into this jet. If the throttle is opened, the suction in this neighborhood decreases, and the idling jet goes out of action. In order to meet the requirements of temporary enrichment of mixture for rapid acceleration, most carburetors designed for applications where this requirement must be met, are provided with some sort of acceleration jet. The operation of the throttle rod may be used to cause a piston to descend in the accelerating well, forcing an extra supply of gasoline from the accelerating jet. The piston fits loosely in the well or cylinder, and has little tendency to pump gasoline out of the accelerating jet if the position of the throttle is changed slowly and smoothly, but the more rapidly the throttle is opened, the higher the pressure set up in the accelerating jet, and the more the temporary enrichment of the mixture.

Thus far, all carburetor principles described have incorporated vertical flow of the air upward and open top gasoline jets. The implied position of the carburetor, then, as is shown in Fig. 1, is below the manifold. Some definite advantages are secured, both in arrangement of the manifolds, in the carburetion, and in the location of auxiliaries about the engine if the carburetor can be placed above the manifold, with the air sweeping downward through it, instead of upward. Such carburetors are called downdraft. The open top jets obviously are not suitable for the downdraft carburetor, but no great difficulty is met in carbureting horizontally out of the jets. In Fig. 5 an idea is conveyed of the system em-

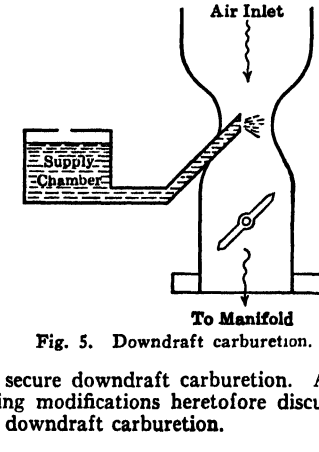


Fig. 5. Downdraft carburetion.

ployed to secure downdraft carburetion. Any or all of the metering modifications heretofore discussed may be applied in downdraft carburetion.

The reader is asked to refer once again to the equation for mixture, and note that if all other terms in the equation were constant, the mixture will again become too rich, because of the decrease of air density, if an engine were employed at increasingly greater altitudes above sea level. Surface vehicles powered by gasoline engines may have their carburetors adjusted from time to time for operation in regions of different altitude, usually by needle valve adjustments which impose orifice-like restrictions in the flow to the main jet. Aircraft may travel into regions of widely varying air density frequently and without the possibility of a static adjustment to compensate for variable air density. Thus, carburetors which are installed on aircraft capable of attaining altitudes where the change of air density would affect the carburetion in a detrimental way, are equipped with mixture control which may be operated manually or may be automatically adjusted by the atmospheric pressure itself. This mixture control is usually either of the *needle valve* or *back suction* type. In needle valve adjustment what amounts to a variable orifice is imposed in the flow line leading to the gasoline jet, and the setting of this orifice may be adjusted by the engine operator through the operation of a mechanical linkage leading to the carburetor. Alternately, the needle valve adjustment may be obtained automatically by spring-loaded bellows whose expansion is a reflection of the existing air pressure, and hence indirectly of the air density. It will be seen in the various figures of this article that the gasoline supply chamber is vented to the atmosphere. If it could be arranged partially to close this vent, and connect the region above the liquid level with the throat of the Venturi, the normal pressure differential delivering gasoline through the jet could be interfered with, and, in fact, completely dispersed at will. By regulating the degree of interference through adjustments of the vent opening (and possibly also the valving of the connection to the Venturi), the jetting pressure could be cut back and a compensation effected for the decreasing density of the air at higher altitudes. This is called back suction control.

The problem in securing good carburetion reaches its maximum difficulty in the supply to airplane engines which are required to engage in acrobatic maneuvers and operate at high altitudes as, for example, fighter airplanes As has been mentioned, float control of supply would have to be replaced by some other system, also vapor lock and ice formation might occur in a conventional carburetor at high altitudes. These difficulties will be overcome by injection carburetion, and, in addition, it might be possible to use fuels of lower volatility. A direct solution of this problem would be to inject metered amounts of fuel directly into the cylinder by injection valves. This relieves the manifold of fuel distribution problems but distributes the fuel system about the engine, whereas there are advantages of keeping the fuel supply system as compact as possible. An injection carburetor which may be a single unit, and thus obtain the simplicity and compactness of the float carburetor, has been built and is in use on military airplanes. This injection carburetor injects a metered spray of fuel into the air inlet at about 5 lbs. pressure. This is sufficient to atomize the gasoline finely and mix it with the air, and the carburetion will be completed while the mixture flows through the supercharger and inlet manifolds into the cylinders. The carburetor is floatless, has automatic mixture control, and allows the power of the engine to be controlled by a throttle rod exactly as in the case of the float carburetor. (F.T.M.)

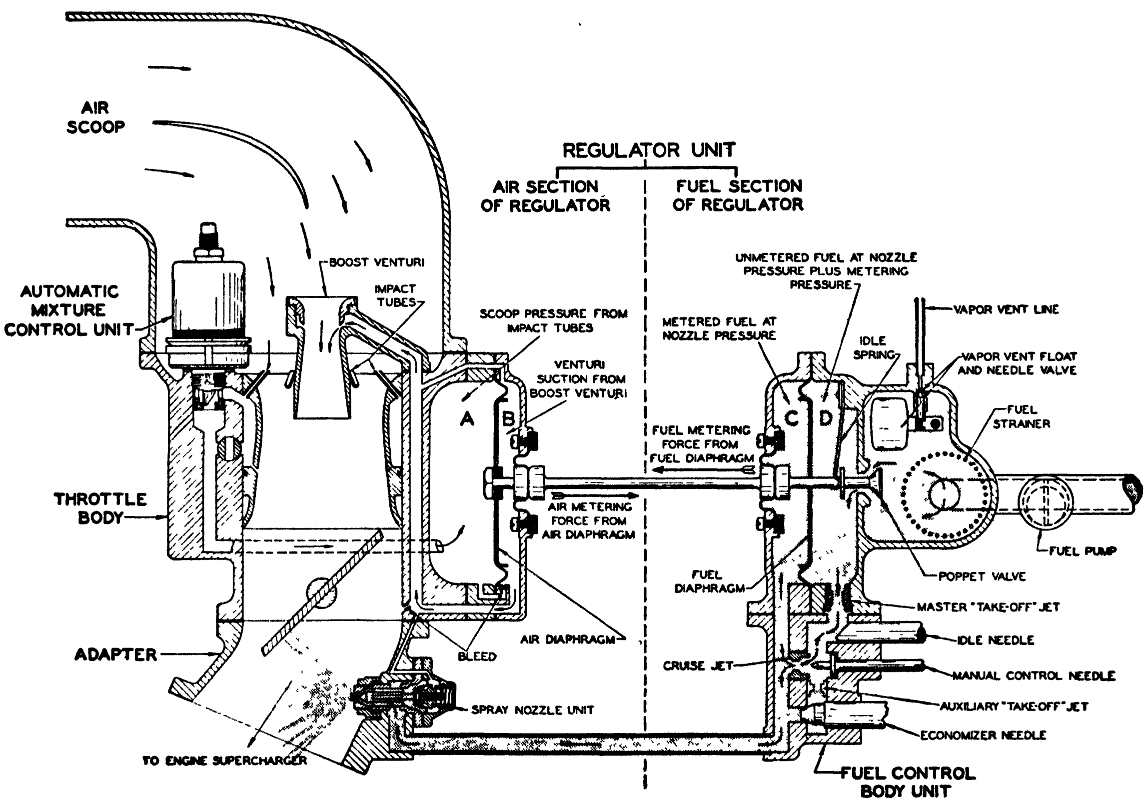

Fig 6 Diagram of injection carburetor (*Bendix Aviation Corp.*)

CARBURIZING. Machine parts requiring high strength, hardness, and toughness can often be made by either of two methods, one based on the use of a medium-carbon steel (.30–.50% carbon) heat treated to

the required properties, and the other based on the use of a low-carbon steel (.08–.25% carbon) carburized to give a high-carbon surface layer and then heat treated. The carburized part will have a harder more wear-resistant surface and a tougher core than the heat-treated medium-carbon steel. Transmission gears, camshafts, and piston pins are typical parts which can be made advantageously of carburizing grade steels.

The process consists of heating the fully machined part in an atmosphere rich in carbon monoxide or hydrocarbon gases at a temperature in the range 1650–1800° F. Reactions at the surface of the metal liberate atomic carbon which is readily dissolved by the steel and diffuses inward from the surface. In a typical carburized case a depth of penetration of .05″ was obtained in 4 hours at 1700° F. The maximum carbon content at the surface was 1.10%. Shallow cases under 0.02″ are useful for many purposes and very deep cases over 0.10″ thick are required for gears for heavy machinery and for armor plate.

The process is most often carried out in sealed containers in which the parts are packed in carburizing compound consisting of a mixture of charcoal, coke, and other carbonaceous solids, together with barium carbonate and other compounds which act as energizers. At high temperatures these solids burn slowly, maintaining a supply of carbon monoxide. Carburizing is also carried out in batch-type and continuous-type furnaces in an atmosphere of natural gas, propane, butane, or specially mixed gases. Liquid baths consisting mainly of molten cyanide and chloride salts are also used for surface hardening. These baths supply both nitrogen and carbon to the surface of the steel, and where nitrogen is the principal hardener the process is known as cyaniding. Nitrogen hardens steel by forming hard compounds with iron and with certain alloying elements that may be present such as aluminum, chromium, and vanadium. (See **Nitriding.**) In general, the salt-bath methods give shallower but harder cases than regular solid-pack carburizing. The pieces are quenched for hardening directly from the bath.

Carburized steels may also be **quenched** in oil or water directly from the box or furnace, or they may be cooled and reheated for hardening. A low temperature **tempering** treatment is given for relief of quenching stresses. A surface hardness of 60 Rockwell "C" is readily obtained, and when medium alloy steels of fine grain size are used, the strength and ductility of the core is exceptionally high, for example, 165,000 lbs. per sq. in. tensile strength and 18% elongation. (R.H.H.)

CARCINOMA. Cancer.

CARDAMOMS. *Elettaria Cardamomum.* Zingiberaceae. Cardamoms are the seeds of a leafy-stemmed perennial **monocotyledon** growing from 5–9′ in height. The flowers, white with purple-striped perianth parts, are borne on leafless stems which rise from the thick fleshy **rhizomes** apart from the leafy stems. The angular seeds are borne in 3-celled fruits. The dried seeds are used in India and elsewhere in tropical Asia as a highly flavored spice. (R.M.W.)

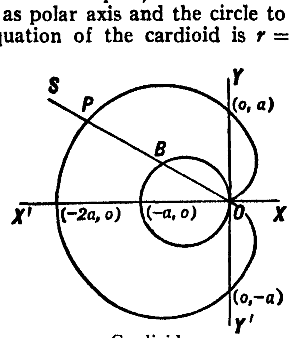
CARDIAC. Pertaining to the heart. (D.M.H.)

CARDINAL TEETH. In the shells of some **bivalve** mollusks, the interlocking prominences of the two valves just below the umbo. (A.W.L.)

CARDIOID. The cardioid is a type of mathematical curve which received its name from its heart-shaped form.

The cardioid may be defined geometrically as follows: From any point O on a circle of diameter a draw any secant OS cutting the circle at B, and extend OB to P so that $BP = a$; as this secant line rotates about O, the point P describes the cardioid.

If we take O as the pole, and OX through the center of the circle as polar axis and the circle to the left of O, the polar equation of the cardioid is $r = a(1 - \cos\theta)$.



Cardioid.

The cardioid may also be defined as the locus of a point on a circle which rolls without slipping on the circumference of an equal fixed circle; this is equivalent to the above definition.

The cardioid has an interesting application to the problem of the trisection of an angle. (L.L.S.)

CARDIOLOGIST. A physician who specializes in the diagnosis and treatment of **heart** disease. (R.S.M.)

CARDO. The basal segment of an insect **maxilla** by which it is attached to the head. (A.W.L.)

CAREY-FOSTER BRIDGE. This is a form of **Wheatstone bridge,** adapted to the measurement of the difference between two nearly equal resistances, with the elimination of errors due to the connections. The bridge is of the slide-wire type (the ordinary 4-gap form is easily adapted to the purpose); the resistance ρ of the slide wire per unit length being accurately known. X and S are to be compared. (See figure.) A balance is

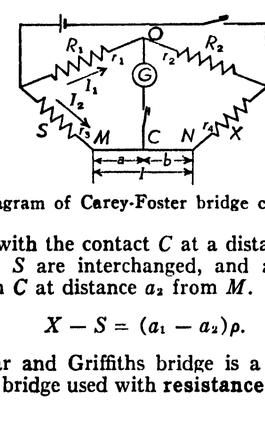


Diagram of Carey-Foster bridge circuit.

first secured with the contact C at a distance a_1 from M. Then X and S are interchanged, and another balance obtained with C at distance a_2 from M. It may then be shown that

$$X - S = (a_1 - a_2)\rho.$$

The Callendar and Griffiths bridge is a special type of Carey-Foster bridge used with **resistance thermometers.** (L.D.W.)

CARIBOU. Mammalia, Artiodactyla. *Rangifer.* Deer with partly flattened branching antlers in both sexes; North American relatives of the European reindeer. The several species inhabit the more northern parts of the continent, although two come into the United States. Caribou are found in northern Maine and in several of the northwestern states. (A.W.L.)

CARIES. Decay or death of a portion of a bone, due to a chronic inflammatory disease. Dental caries is decay of the enamel, dentin or pulp of a tooth. Spinal caries is Pott's disease (tuberculosis of the spinal column). (R.S.M.)

CARINA. 1. A sharp ridge, comparable with the keel of a boat, such as is found on the shells of certain **snails.** 2. The median dorsal plate of the shell of a

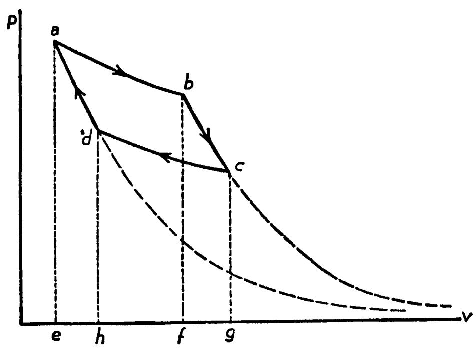
barnacle. 3. The deep ridge on the breastbone of most birds (**Aves**), more often called by the English equivalent, keel. (A.W.L.)

CARINATAE. A division of the birds (**Aves**) including all of the flying species which have the breastbone provided with a deep keel for the attachment of the powerful flight muscles. The division includes a few species which do not fly and which have only a rudimentary keel. The classification of birds as Carinatae and Ratitae is now rather generally abandoned in favor of subdivision into orders without such grouping. (A.W.L.)

CARNELIAN. The mineral carnelian is a red or reddish-brown **chalcedony**; the word is derived from the Latin word meaning flesh, in reference to the flesh color sometimes exhibited. (E.S.C.S.)

CARNIVORA. An order of **mammals** made up largely of flesh-eating species, mostly predacious in habits, although some are omnivorous and some eat carrion. They have four or five toes on each foot, armed with claws, the canine teeth are prominent, and the premolar and molar teeth are formed for cutting. Common examples of the several families into which the order is divided are the **bears**, the **wolves**, the **raccoons**, the **weasels**, **minks**, and **skunks**, and the **cats**. (See also **Pinnipedia**.) (A.W.L.)

CARNOT CYCLE. An ideal cycle of four reversible changes in the physical condition of a substance; useful in thermodynamic theory. Starting with specified values of the variable temperature, specific volume, and pressure, the substance undergoes in succession (1) an isothermal (constant temperature) expansion, (2) an adiabatic expansion (see **Adiabatic Processes**), and (3) an isothermal compression to such a point that (4) a further adiabatic compression will return the substance to its original condition. These changes are represented on the



Carnot cycle on v-p diagram ab and cd, isothermals; bc and da, adiabatics, which for some theoretical purposes, are produced to infinity.

volume-pressure diagram respectively by *ab*, *bc*, *cd*, and *da* in the accompanying figure. Or the cycle may be reversed: *a d c b a*.

In the former (clockwise) case, heat is taken in from a hot source and work is done by the hot substance during the high-temperature expansion *ab;* also additional work is done at the expense of the thermal energy of the substance during the further expansion *bc*. Then a less amount of work is done on the cooled substance, and a less amount of heat discharged to the cool surroundings, during the low-temperature compression *cd;* and finally, by the further application of work during the compression *da*, the substance is raised to its original high temperature. The net result of all this is that a quantity of heat has been taken from a hot source and a portion of it imparted to something colder (a "sink"), while the balance is transformed into mechanical work represented by the area *abcd*. If the cycle takes place in the counter-clockwise direction, heat is transferred from the colder to the warmer surroundings at the expense of the net amount of energy which must be supplied during the process (also represented by area *abcd*). The operation of the cycle thus illustrates the second law of **thermodynamics**. (L.D.W.)

CARNOTITE. The mineral carnotite is a **vanadate** of **potassium** and **uranium** with small amounts of **radium.** Its formula may be written $K_2O \cdot 2UO_3 \cdot V_2O_5 \cdot 2H_2O$. The amount of water, however, seems to be variable. It occurs usually as a lemon-yellow earthy powder disseminated through **sandstones**, rarely as **orthorhombic** shales. It was mined in Colorado and Utah, as a source of radium. Other localities are in Arizona, Pennsylvania, and the Belgian Congo. (E.S.C.S.)

CAROTENE. Pigments in Plants.

CARP. Pisces, Teleostei. Large **fishes** belonging to the same family as the minnows, dace, and chubs. The common carp is an introduced species, indigenous to eastern Asia but now thoroughly at home in the rivers and lakes of North America and Europe. It is coarse and bony but it is widely used as food. The **goldfish** or golden carp is a related species native to China and Japan. Many strange varieties have been developed in captivity and the species is thriving in some lakes and streams in the eastern United States. Several other species of carp occur in Europe and Asia. (A.W.L.)

CARP SUCKER. Pisces, Teleostei. *Carpiodes*. Fishes (**Pisces**) of several species related to the buffalo and suckers. They are found in streams and lakes of the United States and Mexico. Most species are known by this name but one member of the genus is called the **quillback.** (A.W.L.)

CARPAL BONES. The small bones of the wrist in man and the similar group in the forelegs of animals. (A.W.L.)

CARPEL. Flower.

CARPENTER MOTH. Insecta, Lepidoptera. **Moths** whose larvae bore in the trunks of trees, entering the solid wood. A few species, including the locust borer, are of large size, and because of their narrow wings and long bodies may be mistaken for sphinx moths. These insects make up the small family Cossidae. (A.W.L.)

CARPENTER-BEE. Insecta, Hymenoptera. A bee which excavates its nest in wood. The small carpenter-bee, *Ceratina dupla*, of North America merely digs out the pith or soft wood of a plant, such as sumac, while the large carpenter-bees, *Xylocopa*, of which there are several species, bore into solid wood, even attacking unpainted wood in construction. The larger bees are not unlike **bumblebees** in appearance. (A.W.L.)

CARPINCHO. Capybara.

CARPOPODITE. The third segment from the tip of the **crustacean** appendage. (A.W.L.)

CARRIAGE. Lathe.

CARRIER. A person who carries the specific organisms of any disease, and who can, though showing no signs of the disease himself, distribute disease through contact with others. Virulent hemolytic streptococci, diphtheria bacilli, and meningococci, may be carried in the throats of healthy individuals; typhoid and the dysentery bacilli may be present in the intestinal tract of healthy carriers. (D.M.H.)

CARRIER CURRENT. Carrier current is used in connection with both power and communication cir-

cuits but, basically, the principle is the same for both systems. The term refers to the use of a relatively high-frequency a.c. superimposed on the ordinary circuit frequencies in order to increase the usefulness of a given transmission **line**. Thus in the case of power systems, carrier currents of several kilocycles frequency are coupled to the 60-cycle transmission lines. These carrier currents may be modulated to provide telephone communication between points on the power system or they may be used to actuate relays on the system. This latter use is known as carrier relaying. Carrier currents have greatly extended the usefulness of existing line facilities of the telephone and telegraph companies. Several carrier frequencies may be coupled to the lines already having regular voice or telegraph signals on them. Each of these carrier frequencies may be modulated with a separate voice or telegraph channel and thus a given line may carry the regular signals plus several new carrier channels, each of which is equivalent to another circuit at regular frequencies. At the receiving end the various channels are separated by **filters** and the signals demodulated and then fed to conventional phone or telegraph circuits. The number of carrier channels which may be applied to a given line depends upon the characteristics of the line, varying from one or two for some lines to several hundred for the coaxial **cable**. (L.R.Q.)

CARRIER FREQUENCY. Carrier Current; Radio Communication.

CARRIER RELAYING. Carrier Currents.

CARRIER WAVE. Radio Communication.

CARRION BEETLE. Insecta, Coleoptera. Moderate to large **beetles** which are found about decaying flesh and to some extent about other decaying matter. Applied to members of the family Silphidae, although many other beetles breed in decaying matter and are found in it, both as adults and as **larvae**. (A.W.L.)

CARRION BIRD. Aves, Falconiformes. The English equivalent of the Dutch name **aasvogel**, applied to some of the larger South African **vultures**. (A.W.L.)

CARROT FAMILY. Umbelliferae. The plants of this family, mostly found in the north temperate zone, are nearly all annual or biennial herbs, with a few trees or shrubs. They are characterized by having stems hollow except at the nodes, alternate leaves which are either pinnately or ternately compound, and large numbers of small flowers produced in simple or compound **umbels**. The distinctive umbel is an inflorescence in which the pedicels of the individual flowers arise from a very short axis and are of nearly equal length, producing a flat-topped or rounded cluster.

The single **flowers** are small and regular, the **calyx** being either absent or adnate to the **ovary**, and five-toothed, the **corolla** composed of five separate **petals**, the stamens five and the single **pistil** with inferior ovary, with two one-seeded **carpels**. The flowers are insect-pollinated. The fruit is a form known as a schizocarp, a dry fruit having two carpels which separate at maturity into two mericarps, each of which usually has five longitudinal ridges. Between the ridges are found longitudinal oil canals containing the volatile oils which give the odors characteristic of many members of this family.

Many members of this family are important food plants to man and domestic animals. Among these are plants grown for their roots, the carrot, *Daucus Carota*, and parsnip, *Pastinaca sativa*, both natives of Europe; also **celery**, *Apium graveolens*, grown for its leaf stalks, and parsley, *Apium Petroselinum*, grown for the much dissected leaves which are used as a garnish and for flavoring. A large number of plants in this family are frequently cultivated, especially in Europe, for flavorings and medicinal use, though possibly their therapeutic value is rather overrated. Among these are **anise** (*Pimpinella anisum*), caraway (*Carum Carvi*), *coriander* (*Coriandrum sativum*), fennel (*Foeniculum officinale*), and dill (*Anethum graveolens*). Many of these are also used in flavoring confections. *Ferula fetida* produces a drug, **asafoetida**.

In contrast to these, which are useful to man, are many members of the family which contain violent poisons. *Conium maculatum*, the Poison Hemlock, is reputed to have been the source of the poison which Socrates drank. *Cicuta maculata* and related species are sometimes eaten by livestock with fatal results. (R.M.W.)

CARTESIAN COORDINATES. Cartesian coordinates of a point are either its **rectangular coordinates** or its **oblique coordinates**. They are called Cartesian after the French mathematician and philosopher Descartes, who first introduced the idea of **coordinates** as a basis for the analytic study of geometry. (L.L.S.)

CARTESIAN OVAL. This curve is defined as the **locus** of a point P that moves so that its distances from the origin $O(0,0)$ and the point $A(a, 0)$, in **rectangular coordinates**, satisfy the relation $AP = \pm b \cdot OP \pm c$, where b and c are given positive constants. (L.L.S.)

CARTHAMUS TINCTORIUS. Safflower. Compositae. This plant, a native of the East Indies, is now widely cultivated in tropical Asia and Egypt, and to a limited extent in southern Europe. It is a low annual plant with yellowish-red flowers which have tubular corollas.

Of commercial importance are the flowers, which are washed in water to remove the yellow pigment present, dried, and ground to a powder. This powder is mixed with starch and talc to make rouge. (R.M.W.)

CARTILAGE. 1. The internal structure of the ligament which connects the valves of the shell in some of the **bivalve** mollusks. 2. A supporting tissue associated with the skeleton of **vertebrates**.

Cartilage, like the other connective and supporting tissues, contains a relatively large amount of intercellular substance in which the cells are scattered. This substance is a complex mixture of organic materials, bluish in color and translucent. It contains organic fibrils and around the cavities in which the cartilage cells lie it differs chemically as shown by its reaction to stains. The cells are rounded and may lie singly or in groups in the capsules.

Three kinds of cartilage are recognized: hyaline, elastic, and fibrocartilage. The first contains few fibrils. It is flexible, slightly elastic, and provides a support of moderate rigidity. It covers the ends of bones in movable joints as the articular cartilages, forms the rings of the trachea, and occurs in other parts of the body where such qualities are required. Elastic cartilage is similar to hyaline but has many elastic fibers in the intercellular matrix. It occurs in the pinna of the ear, where its qualities provide support and elasticity, the latter very necessary in a delicately formed projecting structure of this kind which might otherwise be easily broken. Fibrocartilage contains many inelastic white fibers which give it extreme toughness. It is associated with some joints and forms the intervetebral disks of the backbone. These disks provide very firm connections between the separate vertebrae and at the same time cushion the series.

The term cartilage is also applied to separate skeletal units formed of this material. Each cartilage is surrounded by a tough connective tissue sheath called the perichondrium.

Cartilage is a primitive skeletal material of the vertebrates. It precedes bone in embryonic development and persists in the adult skeleton in the sharks and related

fishes. It is not transformed into bone but is replaced by bone in the formation of some of the parts of the skeleton. It may become rigid through the deposition of calcareous material in its matrix, particularly in old age. This calcified cartilage, while rigid like bone, does not have the minute structure of that tissue. (A.W.L.)

CARYOPSIS. **Fruit.**

CASCARA SAGRADA. The bark of *Rhamnus Purchiana,* a shrub growing in western North America. It is a **drug** used as a laxative and cathartic. (R.S.M.)

CASE HARDENING. **Carburizing, cyaniding,** and **nitriding** are the principal methods of case hardening steels. (R.H.H.)

CASEIN. Casein is a protein present in milk that is used to make **plastics.** (See **Aminoacids, Polypeptides and Proteins, Adhesives, Pigments, Paints, Varnishes.**) (R.K.S.)

CASHEW. *Anacardium occidentale.* The cashew nut is the fruit of a Brazilian tree of moderate size. The kidney-shaped nut grows at the end of a curiously enlarged fleshy **peduncle** which is juicy and bright yellow or red. This fleshy portion is much eaten in tropical America. The nut itself contains a biting caustic **oil** which is driven off by roasting. The single kernel of this fruit is the familiar cashew nut so widely known as a confection. The oil is used to a limited extent, to protect book bindings and wood against the attack of **termites.** (R.M.W.)

CASING. The casing is that part of a machine which encloses or encases the working portions. Not all machines are said to have a casing; the term is usually applied in instances where a nearly complete enclosure is made, such, for example, as the fan casing and the turbine casing.

The pipe which is used to line a well is called casing pipe, and is a prominent feature of oil and gas wells. It is usually characterized by light weight, and joints with fine pitched threads. In sinking a deep well the casing constituting the first section may be 6″ in diameter. When the 6-in. casing has been sunk as deep as practicable, the size will be stepped down to, say, 5″, which is lowered into the well inside the 6-in. casing. Thus progressively the size of the casing is decreased as the well deepens. (F.T.M.)

CASINGHEAD GAS. A large amount of technically pure **gasoline** termed casinghead or "aviation gas" is now extracted by condensation from vapors present in certain **natural gases** as they flow from the well. This product is also used to blend with gasoline which has been refined from **petroleum.** (R.M.F.)

CASSAVA. **Spurge Family.**

CASSEGRAINIAN. **Telescope.**

CASSIA. *Cinnamomum cassia.* Lauraceae. Cassia, or Chinese Cinnamon, is one of the earliest used of all spices, and is mentioned in the Old Testament as a spice. It is a bushy plant native to Cochin China, from which region it had spread in cultivation to much of southeastern Asia in early times. Its presence in the island of Ceylon led the Portuguese to seize that island in 1636. That and other spices were the main cause of the bitter and bloody struggles among various European nations for possession of tropical Asian lands.

In cultivation the much-branched plant is ready for harvest about six years after planting. In harvesting, the bark on the young stems is split longitudinally and peeled back in cylinders about 16″ long. The adherent **periderm** is planed off. With continued drying the bark rolls up rather tightly and turns dark brown in color. This is the product used mainly as a spice in pastry making. Immature fruit may be dried and also used for spice.

By distillation, oil of cassia, mainly cinnamic **aldehyde,** is obtained from the bark and leaves. This oil is used mainly as a flavoring for candies. Some of it is used in making scented soaps, and in medicines, where its principal value is in concealing unpleasant tastes.

The name Cassia is also applied to two unofficial drugs, Cassia pulp, which is the fruit pulp of *Cassia Fistula;* and American Senna, the dried leaves of *C. marilandica,* both from the family Leguminosae. (R.M.W., B.S.M.)

CASSIOPEIA. (Map, page 380.) This is one of the most widely known and striking **constellations** of the northern latitudes. It is easily recognized by the 5 bright stars forming an irregular W, some observers seeing not only a W but also a chair. Since this object is circumpolar (i.e., remains above the **horizon** at all hours every night) for most northern countries, and is easily recognized, it is frequently used as a rough indicator of sidereal **time.** The leading bright star of the W (the star Beta Cassiopeiae) lies almost in zero hours **right ascension.** Hence a line drawn through **Polaris** and Beta Cassiopeiae must pass close to the vernal equinox. The **hour angle** of this line must be equal to sidereal time. Hence when Beta Cassiopeiae is on the meridian directly above the pole the sidereal time is zero, when on the meridian directly below the pole the sidereal time is 12 hours, etc.

One of the brightest **novae** on record appeared in this constellation in 1572 and was observed and recorded by Tycho Brahe. (W.K.G.)

CASSIQUE. Aves, Passeriformes. South American birds (**Aves**) of several species, related to the Old World starlings. (A.W.L.)

CASSITERITE—TIN STONE. The mineral cassiterite, chemically **tin** dioxide, SnO_2, is almost the sole ore of tin. It is a noticeably heavy mineral crystallizing in the **tetragonal** system, as low pyramids, prisms, often very slender, and as twinned forms. It is a brittle mineral, hardness, 6.0–7.0; specific gravity, 6.8–7.1; luster, adamantine; color, generally brown to black, but may be red, gray to white, or yellow; streak whitish, grayish, or brownish; may be almost transparent to opaque. A fibrous variety somewhat resembling wood is called wood tin. Cassiterite occurs in widely scattered areas, but deposits of a size to be commercially important are few. It is associated with **granites** and **rhyolites** and is believed to be, in part at least, the result of **pneumatolytic** action. The weathering of the cassiterite bearing rocks often permits the distribution of it along stream beds where it is known as stream tin. The Malay Peninsula deposits are stream tin. Other productive regions are Australia, Africa, and South America. In the United States cassiterite has been mined in the Black Hills of South Dakota and elsewhere but the deposits are not of great consequence. The tin veins, now about exhausted, in Cornwall, England, were known to the Phoenicians before the Roman invasions. Saxony and Bohemia were formerly important producing regions also.

The word cassiterite is of Greek origin. (E.S.C.S.)

CASSOWARY. Aves, Casuariiformes. *Casuarius.* A large flightless bird (**Aves**) of Australia, New Guinea, and adjacent islands. The several species are all forest birds, unlike the related **emus.** The naked skin of the head and neck is brightly colored with blue, green and red, and the head is surmounted by a bony crest, in some species of large size. The wings are rudimentary. (A.W.L.)

CAST IRON. Cast iron is the product of remelting and casting **pig iron.** The melting furnace is usually a **cupola** but other types of melting equipment including **electric-arc furnaces** may be used for special grades. In the melting process the composition can be changed from that of the pig iron by additions to the charge of steel and sometimes of alloying elements. However, the iron is not refined as in steel-making; that is, no considerable amount of phosphorus, sulfur, silicon, or manganese is removed from the charge. The total of these elements plus the carbon content may be 7% in a typical cast iron compared to 1% in a typical steel. The high carbon content of pig iron is largely retained in cast iron, about 3.25% being normal for general purpose cast irons. By the addition of considerable steel scrap to the charge, and by other means, the carbon can be reduced to between 2 and 3%, with considerable improvement of the strength of the castings. A large part of the carbon is present in the form of flakes of **graphite** (see photomicrograph), which accounts for the relatively low tensile strength and the characteristic gray appearance of the fracture of high-carbon gray cast irons.

The silicon content, or the silicon-carbon balance, plays an important part in determining the structure and properties of cast iron. Silicon promotes graphitization of the carbon, hence reduced silicon content favors higher strength. When both carbon and silicon are low, it is possible to cast a graphite-free iron known as white cast iron. This product is not, however, high in strength because much of the carbon is present as **cementite** which is very brittle; thus the hardness and wear-resistance is high but the tensile strength is low. Most white cast iron is converted to malleable cast iron by annealing at high temperatures; however, certain hard alloy grades (see Ni-Hard in table) are used in the as-cast state for abrasion-resisting applications.

In the annealing of white iron castings for malleablizing, a considerable part of the carbon is removed by oxidation at the surface and the remainder of the cementite is converted to graphite and ferrite. The nodular graphite, or temper carbon, of malleable cast iron (see photomicrograph) can readily be distinguished from the flake graphite of gray cast iron. Whereas gray iron is relatively brittle, good malleable iron has a ductility of about 20% in 2″ and a tensile strength of 50,000 lbs.

TYPICAL CAST IRONS

No.	Composition, %								
	C	Si	Mn	P	S	Cr	Ni	Mo	Cu

No.	Application
1	Automobile cylinder blocks, plain iron
2	Automobile cylinder blocks, alloy iron
3	Automobile cylinder blocks, alloy iron
4	Piston rings, individually cast
5	Heavy section (1.5″ thick) castings
6	Light section sand cast water pipe
7	Car wheels
8	Brake drums
9	Machine tool beds
10	Crankshafts
11	Crankshafts (Ford analysis)
12	White iron for malleablizing
	Special Alloy Compositions
13	Ni-Hard—a very hard white iron for crushers, grinders, ball mills, etc.
14	Ni-Resist—a corrosion and heat resistant cast iron for processing equipment, furnace castings, manifolds, etc.
15	Duriron—acid resisting castings

(R.H.H.)

per sq. in. Specially treated malleable iron known as pearlitic malleable has even better mechanical properties. Malleable irons are used for small castings requiring greater toughness and ductility than ordinary gray cast irons; for example, automobile brake levers, pump parts,

Fig. 1. Graphite flakes in cast iron at 100 times magnification. Not etched. (See **Metallography**.)

and numerous parts for agricultural implements. Pipe fittings are another important application.

A white cast iron structure can be produced locally in a gray iron casting by the use of chills in the mold if the composition is properly balanced; thus chilled cast iron freight-car wheels and cast iron brake shoes have hard white iron wearing surfaces and gray iron

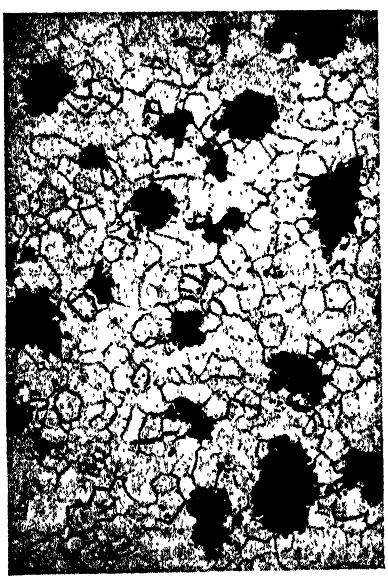

Fig. 2. Temper carbon in matrix of ferrite grains in malleable cast iron. 100 times magnification. Etched in a solution of nitric acid in alcohol.

cores. If an entire wheel were white iron it could not be bored or machined by ordinary methods and would fail in service because of excessive brittleness. On the other hand, if the tread were gray iron it would be too soft for good wear-resistance in this type of service.

Cast iron is ordinarily thought of as a cheap low-strength material. In recent years the foundry industry has found methods for increasing its strength without sacrificing its inherent good machinability, ease of casting, and excellent bearing qualities. These methods include (1) lowering the carbon and silicon content by the use of steel scrap in the charge, (2) addition of alloying elements to a properly balanced base mixture, (3) superheating the molten metal and inoculating with a graphite-forming agent in the ladle before casting. High-strength Meehanite cast irons are made by a patented process in which a graphitizing ladle addition is made to a melt which would otherwise be white or mottled in structure. Whereas the tensile strength of an ordinary gray iron casting may be only 20,000 lbs. per sq. in., various higher strength grades are made with up to 60,000 lbs. per sq. in. tensile strength.

High-alloy irons such as Ni-Resist and Duriron have special corrosion-resisting qualities.

CAST STEEL. Steel.

CASTING. Casting is the process of producing metal shapes by pouring molten metal into molds of the required form where it is allowed to solidify. The metal part formed as a result of this operation is called a casting. The art of casting is one of the oldest methods for making metal parts and is still extensively used in spite of more modern developments such as **forging.**

The production of a casting involves the use of a pattern, usually of wood or metal, which is similar in shape to the desired finished piece and slightly larger in all dimensions to allow for shrinkage of the metal upon solidification. The pattern is bedded down in a special damp sand by an operation called molding. When the pattern is removed it leaves an impression of the shape of the desired casting. This impression is completely surrounded by sand and provided with openings called gates through which the molten metal enters. After pouring and cooling the mold is broken open and the casting removed. All adhering sand particles together with any extraneous projections such as those left by the gate system are removed after which the casting is machined to the required finish.

The term is also applied to the casting of **pig iron** in **blast furnace** practice and the casting of **ingots** in steel-mill practice.

Centrifugal casting is applicable to the production of pipe and tubing, wheels, gear blanks, and other castings having rotational symmetry. While the mold is rotated on a horizontal axis for pipe and tubing, and on a vertical axis for wheels and gear blanks, a measured amount of molten metal is added. The mold may be sand or water-cooled metal for more rapid solidification. Centrifugal castings have good structure and density.

Metal molds are also used for making die castings and permanent mold castings. In the latter process a permanent metal mold is filled by gravity in the usual manner, while in die casting considerable pressure is exerted on the molten metal, insuring rapid and complete filling of the mold. Die-casting machines are highly mechanized for rapid and nearly automatic operation. The product is characterized by high dimensional accuracy and clear reproduction of mold details including screw threads, holes, and intricate sections, all of which greatly reduces the machining required. The process is limited in its application by the high cost of making alloy steel dies or molds. The lower melting **zinc alloys** and **aluminum alloys** are most successfully die cast; however, certain **brasses and bronzes** can also be die cast. Tin- and lead-base alloys are easily die cast but have limited application.

The zinc-base die-casting alloys are the most widely used. A typical composition is 1.0% copper, 3.9% aluminum, 0.06% magnesium, balance zinc. This alloy has a strength of about 45,000 lbs. per sq. in. with 3%

elongation in 2″. Typical applications are carburetors, fuel pumps, tools, typewriter frames, instrument cases, and hardware which is often finished by chromium plating.

The investment or "lost wax" process has lately been revived as a method of making precision castings of metals such as steel, etc., having too high a melting point for die casting. A wax pattern is made in a die-casting machine, sprayed with a highly refractory slurry, dried and imbedded in sand. The mold passes through a furnace where the wax is melted out and recovered, and the mold baked. The casting is then poured into the cavity left by the melting out of the wax, resulting in castings which rival die castings for dimensional accuracy. (C.W.C., R.H.H.)

CASTOR. Castor (α **Geminorum**) is the fainter star of the twins. Since these two stars are always considered together in the ancient literatures, the history and astrological significance will be found discussed under **Pollux,** the brighter of the two.

Astronomically, Castor is a very remarkable star. It was discovered in 1719 to be a visual **binary,** with the **magnitudes** of the components 2.8 and 2.0. The separation is about 6″ and the star is certainly a true binary, but the period has not yet been accurately determined. The period is probably of the order of magnitude of 350 years. Each of the two components of the binary system is also a **spectroscopic binary** so Castor is a quadruple system. Castor has a faint companion separated from it by about 72″ but having the same **parallax** and **proper motion.** This companion is also a spectroscopic binary with a period of slightly less than 1 day. (W.K.G.)

CASTOR OIL. *Ricinus communis.* Euphorbiaceae. Castor oil is obtained from a short-lived perennial tree which occurs wild in tropical Africa and perhaps in India. Cultivation of the tree is widespread not only in the tropics but also in temperate regions, where it is often grown as an ornamental plant. In the tropics it becomes a tree 36′ tall, with large coarse leaves often of reddish color, and green flowers. An annual herbaceous variety is grown widely and produces a superior oil. The seeds, borne three in each of the smooth or prickly capsules, have a hard mottled shell. These seeds are ejected violently from the mature fruit.

The principal use of the plant is for the oil which is contained in the seeds. This oil is pressed out without heating the seeds. It is used as a lubricant for airplane and marine engines, either in the pure state or mixed with mineral oils. Much castor oil is used in preparing various dyes used in coloring textiles. Certain soaps, also, are prepared from castor oil. (See **Esters.**) Not a little has been used as a lubricant for the human system where, however, its action has proved mildly irritating. The seeds contain a violent poison which must be removed before the oil can be used medicinally. India produces most of the castor bean crop of today. (R.M.W., B.S.M.)

CASUARIIFORMES. An order of flightless birds (**Aves**) containing the **emus** and **cassowaries** of Australia and New Guinea. (A.W.L.)

CAT. Mammalia, Carnivora. Although commonly used in the unqualified form only to designate the domestic cat, *Felis domestica,* this term properly indicates any member of the large family Felidae, which includes the **lion, the tiger, leopards, lynxes,** and many species of smaller size.

Among the distinctive characters of the family are the simple dentition and the sharp, curved, retractible claws. In most species the claws can be withdrawn completely into sheaths.

The larger cats of the Old World include the lion, tiger, leopards, and the moderately large serval, jungle-cat, and **caracal,** all African and Indian species. In North America the only large form is the **puma** or mountain lion, also known as the panther, painter, catamount, and cougar, which is represented by four species ranging from Florida to the west and northward in the Rocky Mountains and in the coastal area. South America has the **ocelot** or tiger cat, the **jaguar,** and the **jaguarondi** cat or eyra, all of which enter Texas by way of Mexico. The lynxes include a European species and in North America the **wildcat** or bobcat, the Canadian lynx, and a few less familiar species. (A.W.L.)

CATABOLISM. **Metabolism.**

CATACLASTIC. As proposed by Teall in 1887 this term has the same meaning as **crush breccias.** This term is also applied to the deformation and granulation of minerals such as may take place during dynamic **metamorphism.** (R.M.F.)

CATACLYSM. Before the doctrine of uniformitarianism (the uniformity of all geologic processes throughout all time) had been promulgated by Sir Charles Lyell, it was believed that mountains, mountain ranges, deep valleys and rugged highlands or other features of the earth's surface had been produced by great and sudden convulsions called cataclysms. The word cataclysm is derived from the Greek words denoting downward and to wash away, i.e., floods; the implication being that great floods or violent earthquakes had been instrumental in producing the relief features of the surface of the globe, now known to be the result of the slow but ever-continuous action of the processes of weathering and **erosion.** (E.S.C.S.)

CATALEPSY. A nervous seizure, marked by absence of voluntary motion and of sensibility. The trance lasts from a few minutes to several days. During the attack, the body is cold and pale, and the pulse and breathing are slow. It commonly occurs in **melancholia** and schizophrenia. (R.S.M., D.M.H.)

CATALYZER. **Catalysis.**

CATALYSIS. This is a phenomenon observed in chemical reactions whereby the reaction between two or more substances is influenced by the presence of a third substance (the catalyst) which remains unchanged in the process. For instance **hydrogen** and **oxygen** gas do not react with each other appreciably at room temperature. The introduction of **platinum** powder produces an instantaneous union of these gases to give water. The platinum is chemically unchanged in this process and if proper precautions are taken can convert an infinite amount of hydrogen and oxygen into water. This is an example of positive catalysis. There are cases known of negative catalysis in which the rate of a reaction is repressed by the presence of a foreign body. An example is the inhibition of the **hydrogen peroxide** decomposition by traces of **acetanilid.** In the case of gaseous reactions in the presence of solid catalysts, the reaction takes place on the surface of the solid and the adsorption of the gaseous reactants and products plays an important role. It has been found that certain substances (called promoters), having themselves but little catalytic ability, when added to a catalyst enhance the latter's catalytic ability. An example is the use of **alumina** to promote the catalytic ability of **iron** for the reaction of **hydrogen** and **nitrogen** to form **ammonia.** Since the catalytic reactions take place on the surface of the catalyst the latter must be prepared in as highly subdivided a state as possible. This is accomplished by using the catalyst in a colloidal state or dispersing it on inert carriers. **Charcoal, alumina, silica gel, kieselguhr,** etc., are com-

mon catalytic carriers. Many catalysts lose their catalytic activity completely when exposed to the action of minute amounts of certain substances called poisons. Thus arsenic compounds poison platinum catalysts. The following are a few of the more important catalytic reactions.

1. **Hydrogen** and **oxygen** react to form water in the presence of **platinum** and other finely divided metals.
2. Hydrogen and **nitrogen** react to form **ammonia** in the presence of iron, and alumina (promoter).
3. Ammonia and oxygen (air) react to form **nitric oxide** in the presence of smooth platinum or platinum-rhodium in the form of fine wire gauze to furnish large surface to weight ratio.
4. **Sulfur dioxide** and oxygen (air) react to form **sulfur trioxide** in the presence of **platinum** or of **vanadium** oxide.
5. **Carbon** monoxide and hydrogen react to form **methane** in the presence of nickel.
6. Carbon monoxide and hydrogen react to form **methanol** in the presence of **zinc** and **chromium** oxides.
7. **Carbon** monoxide and hydrogen react to form a synthetic gasoline (Fischer-Tropsch Process) in the presence of cobalt-thoria or nickel-thoria supported on kieselguhr.
8. Liquid fats and hydrogen react to form solid fats in the presence of nickel.
9. Coal and hydrogen react to form **petroleum** (Bergius Process), in the presence of various catalysts.
10. Carbon monoxide and oxygen react to form carbon dioxide in the presence of copper and manganese oxides. (See also **Chemical Changes** and **Hydrogenation.**) (R K.S.)

CATALYST. Catalysis.

CATAMOUNT. Mammalia, Carnivora. The **puma** or mountain lion. Sometimes applied to the **wildcat.** (A.W.L.)

CATARACT. Any opacity which develops in the crystalline lens of the **eye** or in the capsule of the lens.

Cataracts may be primary or secondary to a systemic disease. They may be partial or complete, stationary or progressive, hard or soft. The most common predisposing cause is age, hence senile cataracts are frequently seen. Other causes, either direct or predisposing, are heredity, faulty intra-uterine development, general diseases of the eye.

Treatment of a cataract uncomplicated by other eye disorders is very successful. Useful and even perfect vision follows in the great majority of cases. The procedure is surgical removal of the lens when vision is impaired. After removal of a cataract, the patient must wear strong convex glasses to compensate for loss of the lens of the eye. (D.M.H.)

CATARRH. An inflammation, usually chronic, of any mucous membrane. The term generally applies to the mouth, throat, or nose; it is, however, vague and rarely used at the present time. (D.M.H)

CATAWBERITE. The term applied by Lieber to a **metamorphic** rock chiefly composed of **magnetite** and **talc.** (R.M.F.)

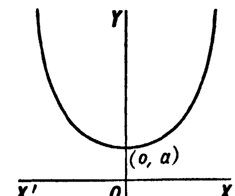
CATBIRD. Aves, Passeriformes. 1. A common North American bird, *Damatella carolinensis,* related to the mockingbird and the thrashers. Although quietly colored in slate gray it is a welcome resident because of its fine singing. 2. An Australian **bower-bird.** (A.W.L.)

CATCHER. **Klystron.**

CATENARY. The catenary is the **locus of the equation**

$$y = \frac{a}{2}(e^{x/a} + e^{-x/a}) = a \cosh \frac{x}{a}.$$

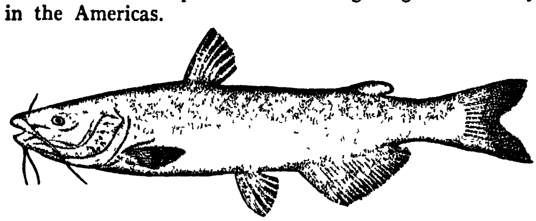
It is the shape of the curve assumed by a uniform, heavy flexible cord freely suspended from its extremities. (L.L.S.)



Catenary.

CATERPILLAR. The larval form of the **butterflies** and **moths.** (A.W.L.)

CATFISH. Pisces, Teleostei. Fishes (**Pisces**) of many species without scales, although the skin has bony plates in some species. Barbels occur on the head. They are represented in the fresh waters of all continents except Australia and gain great diversity in the Americas.



Catfish.

The catfishes are important food fishes in some parts of the world. In North America the channel cats are especially desirable They reach a large size in some of the larger rivers and lakes.

Some of the species included in the group whose names do not indicate the association are the **bullheads,** horned pout, goujon or mud cat, mad toms, and the wels of Europe. (A.W.L.)

CATGUT. Sheep's intestine which has been treated, made **aseptic,** and prepared into strands of various strengths for use in surgery as an absorbable **suture** or **ligature** material. Chromic catgut is treated with **chromium** trioxide and takes a longer time to be absorbed by the body than plain untreated catgut. (D.M.H.)

CATHETOMETER. **Comparator.**

CATHODE. In the nomenclature of the **electrolytic cell,** the negative electrode is designated as the cathode. In a gas-filled or vacuum tube of two elements, the filament is called the cathode.

The cathode might well be called the heart of the electron **tube** since it is the source of the primary **electrons.** It is the electrons which are controlled in various ways to give the multitude of types and applications of such tubes. Cathodes may logically be divided into two groups according to their condition of operation: thermionic or hot cathodes, and cold cathodes. The thermionic type is used in all vacuum tubes and in many gas-filled tubes. It is heated by passing an electrical current directly through it, in which case it is called a directly heated or filament type cathode, or by passing the current through a special heating element enclosed in the cathode, in which case it is called an indirectly heated cathode. The filament type is used in most large radio transmitting and industrial **vacuum tubes** and **thyratrons,** while the indirectly heated type is used in most radio receiving tubes and many smaller industrial types. In either type, however, the mechanism is the same, the so-called free electrons in the cathode are given enough energy by thermal means to overcome the restraints of the cathode surface and pass beyond the boundary, i.e., they are emitted

Once free of the cathode they may be controlled in various ways to give us the many types of tubes which are now available. The amount of energy necessary to overcome the surface restraint is called the work function of the cathode. Various materials have been developed to give more electrons for a given amount of heating energy, but only three are used to any great extent at present. These are pure tungsten which is suitable for operation at very high voltages but requires rather high temperatures for appreciable emission, thoriated tungsten which is a combination of tungsten, thorium oxide and thorium, and finally a combination of barium and strontium oxides. Both of these composite cathodes are more efficient than pure tungsten but cannot be operated satisfactorily at as high voltages (voltage between the cathode and other tube electrodes), so are used in medium- and low-voltage tubes. Both must be put through special processes, called activation, to get the desired characteristics. This is done after the cathode is assembled in the tube and while the tube is being evacuated. Cold cathodes are used in certain grid-glow tubes, in many electronic light source tubes, in phototubes and various types of gas-filled tubes. The mercury pool cathode is a sort of cross between the cold and hot cathode types since it is not heated by extra heating current, but does get an appreciable part of its emission from the heat generated by the passage of the main discharge current. The photocathode, used primarily in phototubes and television camera tubes, depends upon the action of light on the surface to give its electrons enough energy to overcome the surface forces. These cathodes are usually composite surfaces prepared to give electron emission with the relatively low amount of energy available from the light. In general, emission from cold cathodes is due to photo-electric action, high electric field emission and bombardment by charged particles. (L.R.Q.)

CATHODE RAYS. An emission from the cathode in a **vacuum tube,** which becomes more conspicuous as the tube is cleared of gas molecules with diminishing pressure. At pressures of 0.01 mm. of mercury or lower, the rays leave the cathode normally to its surface and move in straight lines across the tube, as shown by the early experiments with the **Crookes tube.** By using a concave cathode, they may be brought to a focus, and any obstacle placed at the focus becomes intensely hot. For some time doubt existed as to the nature of these rays, but Sir J. J. Thomson finally proved that they are negatively electrified particles with a **charge-mass ratio** now known to be of about 1.76×10^8 coulombs per gram; and that they move with speeds varying with the voltage but commonly of the order of $\frac{1}{3}$ the speed of light. We now know that they are **electrons,** released from the metal of the cathode and driven away by its negative voltage.

Lenard (1898) showed that cathode rays will penetrate through thin aluminum or gold leaf and can thus be allowed to pass outside the tube. Electrons so escaping are called Lenard rays. Recent technique due to Coolidge and others has produced Lenard rays of such high speed as to be comparable to the **beta rays** from radium. (L.D.W.)

CATHODE-RAY TUBE. This is a special form of vacuum tube used in various electronic applications, e.g., as the picture tube of the television receiver and as an oscilloscope tube. The tube consists fundametally of three sections enclosed in an evacuated bulb. The first is the electron gun which produces and projects down the tube a beam of electrons. This gun has a **cathode,** usually indirectly heated, which emits a plentiful supply of electrons, then a **grid** which controls the number of electrons drawn towards the anode and finally the **anode.** Both the grid and anode are different in structure from the corresponding elements of the conventional vacuum **tube.** They consist of metal cylinders, coaxial with the cathode and closed at the end except for a small circular hole. Many of the electrons which are drawn towards the anode under the influence of the grid and anode voltages pass through these holes and are projected as a beam into the main part of the tube. Here they are focused upon the screen by electric or magnetic fields in a manner analogous to the focusing of light rays by a lens system. In passing down the tube the beam passes between two sets of plates, called deflecting plates, which are perpendicular to one another. A voltage applied to either of these sets will deflect the beam towards the positive plate. Sometimes the plates are omitted and coils outside the tube substituted. A current through the coils will set up a magnetic field and hence cause deflection of the beam. Finally the beam hits the screen which is a coating on the end of the tube of some material which will fluoresce under the impact of the electrons. Reference to Fig. 1 will show the relative positions of the various parts of the tube. A brief description of the

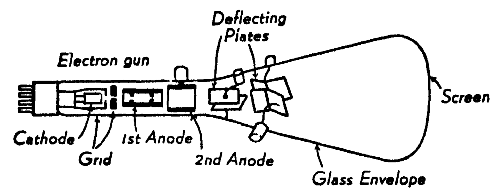


Fig. 1. Typical cathode-ray oscilloscope tube.

use of the tube as an **oscilloscope** will indicate its possibilities. The oscilloscope is used primarily for studying the current or voltage wave forms present in a circuit which is being investigated. If the voltage being studied is connected to one set of the deflecting plates it will cause the electron beam in the tube to move back and forth as the voltage varies. This will cause the fluorescent spot on the screen to move, and due to the persistence of the screen it will appear as a line. If now, another voltage is placed on the other set of plates it will move the beam and hence the screen spot, the resultant being a line pattern which is a combination of the effects of both voltages. Usually the second voltage is a sawtooth wave which gives linear (with respect to time) deflection of the spot and hence the pattern will be the same as if the first wave were plotted on conventional rectangular coordinates. For current study either the voltage drop, caused by the current through a resistor, is used or the current is passed through the coils of the magnetic deflection type. For use as a television picture tube the picture signals are applied to the various electrodes so the fluorescence of the screen is a reproduction of the original scene being televised. (L.R.Q.)

CATHODE SPOT. Mercury-Arc Tube.

CATIONS. Cations are positively charged **atoms** or **radicals.** (R.K.S.)

CATKIN. Ament.

CATLINITE. A red, siliceous **clay** occurring in Minnesota. (R.M.F.)

CATNIP. Mint Family.

CAT'S-EYE. This name is applied to varieties of several mineral species that enclose fine fibers or cellular structures in parallel arrangement, causing, particularly when cut and polished *en cabochon,* a band of reflected light to play on the surface of it. Because of fancied resemblance to the eyes of cats, such stones are called cat's-eyes, and the effect is referred to as chatoyancy. The stone is said to be chatoyant. True cat's-eye is a variety of **chrysoberyl,** but **tourmaline** and **quartz** are also found which show this same effect. Ordinary quartz

cat's-eyes are a pale yellowish or greenish, but a beautiful golden-yellow sort is known from South Africa called tiger's-eye which probably represents a replacement of **crocidolite** by quartz. (E.S.C.S.)

CAT-TAILS. *Typha latifolia* and related species. Typhaceae. These are well-known plants growing in marshy places and along the margins of ponds and slow-flowing streams. Usually they form extensive stands, crowding out nearly all other plants. The cat-tail plant has a thick horizontal **rhizome** which grows along the surface of the ground or just beneath it, generally in several inches of water. From this rhizome the long linear leaves grow in erect bunches. These leaves have widely overlapping bases and are from 3–6′ long. The flower stem rises stiffly erect in the center of the bunch of leaves and is from 3–8′ tall. Near its tip the cat-tail bears two dense cylindrical spikes of flowers, one above the other, which are unisexual. The **pistillate** flowers are found below the **staminate** flowers. Each staminate flower consists of from 2 to 5 or more stamens surrounded by a number of hairs. Soon after the pollen grains are shed the staminate flowers drop off, leaving the naked tip of the stem projecting above the pistillate spike. Each pistillate flower consists of a single pistil surrounded by a group of long hairs. Cat-tails are entirely wind-pollinated. After pollination the **ovaries** develop to 1-seeded **achenes** surrounded by the fine hairs. These fruits form the familiar black or dark-brown cat-tail of late summer and fall. The seeds are blown about by the wind, the long hairs greatly aiding in distribution.

The dried leaves of cat-tails were formerly used in making the seats of rush-bottomed chairs. The hair-covered seeds have been used to a slight extent for stuffing for pillows and small things. The entire fruiting stem is often used as an ornament. (R.M.W., B.S.M.)

CATTLE. Mammalia, Artiodactyla. Broadly applied to all bovine animals, including oxen, buffaloes, sheep, goats and others but more commonly restricted to the **buffaloes, oxen,** and related species and especially to the domesticated races. (A.W.L.)

CAUCHY-RIEMANN DIFFERENTIAL EQUATIONS. Analytic Functions of a Complex Variable.

CAUCHY'S THEOREM ON ANALYTIC FUNCTIONS. If $f(z)$ is an **analytic function of a complex variable** z which has no singularities within or on a given closed curve C, then $\int_C f(z)\,dz = 0$, where the integral is extended over the entire contour C. (L.L.S.)

CAUDAL FILAMENT. A median jointed appendage resembling an antenna and sensory in function, found in some of the primitive **insects.** (A.W.L.)

CAUDATA. Urodela.

CAULDRON-SUBSIDENCE. A term proposed by E. B. Bailey and other Scottish geologists for the sinking of the portion of the roof or cover of a deep-seated **igneous intrusion,** aided by circumferential **faults.** (R.M.F.)

CAULIFLOWER. Brassica.

CAUSAL VARIABLE. Let a variable Y depend directly on a variable X, then X is said to be a causal variable. Naturally there must be a logical connection between the two variables and not merely an association. (L.A.A.)

CAUSTIC. Term applied to bases or alkalis. Caustic potash, **potassium hydroxide**; caustic soda, **sodium hydroxide**; caustic line, **calcium** oxide; lunar caustic, **silver nitrate.** (R.K.S.)

CAUSTIC EMBRITTLEMENT. Water, Utilization.

CAUSTICS. Spherical Aberration.

CAVE. A cave is a natural opening in the earth's surface, and from time immemorial caves have attracted much attention because of the inherent mystery suggested by them or from the fact that they have been used as the refuge of robbers, as depositories for their plunder, and as the first habitations of primitive man. Caves are chiefly developed in **limestone** regions where because of the easy solubility of **calcium** carbonate the ground water succeeds in dissolving and carrying away large quantities of this otherwise physically resistant rock. The water enters through the joint cracks or

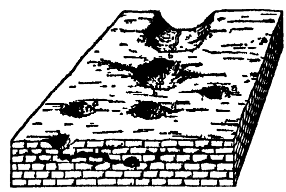

Diagram illustrating the origin of caves (in black), sink holes (a), and natural bridges (b) in limestone. (*After H. F. Cleland.*)

bedding planes, passing downward by gravity until it becomes saturated with calcium carbonate or reaches the ground water level where more or less complete saturation exists. With the continued solution of the limestone, large channels and even great underground chambers are formed. The steady removal of the limestone in solution thus tends to weaken the whole formation with the result that the roofs of underground channels or chambers frequently collapse, forming depressions varying in size from a few feet in depth and of small area to those of many acres and 100′ or more in depth. Such fallen-in areas are called sink holes or simply sinks. If they contain water they are then referred to as sink-hole lakes. Sometimes after the continued collapse of the roofs of caverns a small portion will remain, thus forming a natural bridge, the classical example of which is the Natural Bridge, Virginia.

Wherever limestones occur, if there is a sufficient supply of ground water, underground drainage will develop.

Among the more famous caverns of the United States are the Luray and Shenandoah Caverns in Virginia, Mammoth Cave, Kentucky, and Carlsbad Caverns in New Mexico.

Certain parts of Florida abound in sink holes and sink-hole lakes. An important feature in caverns is the so-called rock icicles or stalactites and their associated stalagmites. (E.S.C.S.)

CAVE-CRICKET. Camel Cricket.

CAVENDISH EXPERIMENT. Gravitation Constant.

CAVIARE, CAVIAR. The roe of **sturgeons,** preserved in brine and used especially as an hors d'oeuvre. (A.W.L.)

CAVITATION. It is possible to operate the blades of a water screw propeller or a hydraulic turbine at a condition such that cavities are formed in the wake or about the blade, resulting in vibrations, loss of efficiency, or corrosion of the blades. The chief cause of trouble with **hydraulic turbine** runners is corrosion and attendant pitting of the blades or buckets. This occurs chiefly in regions of high vacuum, as, for instance, near

the **draft tube,** and is probably due to the liberation of oxygen from the water at low vapor pressure. The use of too-high **specific speed** for the head available is thought to aggravate this trouble.

When the engines or turbines of a ship drive the propeller blade through the water at excessive speeds the blade may move through the water faster than the water can close in around it. The cavities that are thus formed cause a great loss of propulsive efficiency, and should be avoided. To avoid cavitation the blades of a marine propeller are made short and wide. (F.T.M.)

CAVITY RESONATOR. Just as the ordinary transmission **line** may be shorted and adjusted to multiples of quarter-wavelengths and used as resonant circuit, the **wave guide** may be closed at the end and, if the dimensions are correct, made to serve as a resonant circuit at **ultra high frequencies.** When used in this manner the guide is known as a cavity resonator. Generally speaking, any hollow metallic cavity can be made to resonate at some frequency dependent on the shape, size and mode of oscillation. The **klystron** makes use of this property of cavities for its operation. (L.R.Q.)

CAVY. Mammalia, Rodentia. Stoutly built **rodents** with short legs and a small or rudimentary tail, represented by the common **guinea-pig.** Among the other species are the **capybara,** largest of the rodents and aquatic in habits, although most of the species are small and terrestrial. All are native to South America. They constitute the family Caviidae. (A.W.L.)

CAYMAN. CAIMAN.

C-BIAS. Bias.

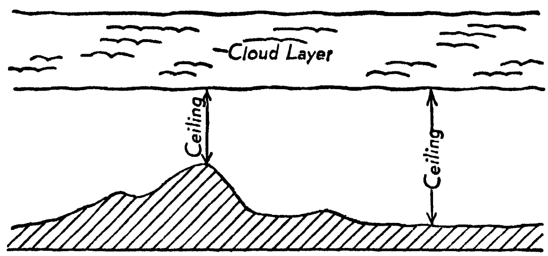
CECOSTOMY. An artificial opening made through the abdominal wall into the **cecum.**. This is done temporarily or permanently to provide an artificial **anus** when the large intestine is obstructed or is the site of certain chronic diseases such as **colitis.** It is also a frequent operation for cancerous ulceration of the large intestine, as a preliminary stage before removal of the tumor. (D.M.H.)

CECUM, CAECUM. A sac-like, blind pouch of the large intestine, situated below the level of the junction of the small intestine into the side of the large intestine. At the lower portion of the cecum, but variable in position, is the **appendix.** (R.S.M.)

CEDAR. Under this name many trees, of several genera, are included. All are characterized by having in the woody tissue an aromatic **volatile oil** which persists for a long time after the tree is cut down and dried. The wood of many cedars is very resistant to rotting, therefore cedar was a favored material for rail fences. The oil present in the wood is repulsive to insects. Among the many cedar trees are *Thuja plicata,* the Western Red Cedar, much used for shingles; *Juniperus virginiana,* Eastern Red Cedar, an important wood used in the making of cedar chests and also lead pencils; *Cedrela odorata,* Spanish Cedar, a tree related to the true **Mahogany** tree, and used in the manufacture of furniture and for cabinet work, also for cigar boxes. In these and in its other uses, Spanish Cedar is frequently cut into thin sheets and applied as a veneer over cheaper woods. Cedar of Lebanon, *Cedrus libanotica,* and White Cedar, *Chamaecyparis occidentalis,* are frequently planted for ornamental purposes, wherever they are hardy. (R.M.W.)

CEILING. Total distance from ground or water vertically to the base of the lowest cloud layer covering more than ½ of the sky. It is one of the most often measured and critical observations in aircraft operation because it is the clearance an aircraft has above terrain before going on instruments.

The term ceiling is used to designate vertical operating limits of an **airplane.** An airplane flies by virtue of expenditure of a certain amount of horsepower by an



engine. When the horsepower thus available from the engine exceeds that required to overcome the air resistance due to motion of the plane, the excess may be employed by the pilot for increasing the velocity or for climbing at constant velocity. However, as the altitude is increased the performance of the internal combustion engine is affected by the rarefied air, with the result that the horsepower available from the engine will have diminished until it is just sufficient to maintain horizontal flight. This altitude is the absolute ceiling of the plane, above which it is not possible to climb. Since theoretically it takes a plane an infinite time to reach absolute ceiling, the service ceiling is a more practical measure of performance. This is the altitude at which the rate of climb has diminished to 100 ft. per min. (P.E K., F.T.M.)

CELERY. *Apium graveolens.* Umbelliferae. A biennial plant growing wild in the marshes of western Europe. The wild plant has a rank taste and strong characteristic odor, but cultivation has resulted in the elimination of these objectionable features, and has produced an enlarged leaf-stalk extensively used as a salad plant. In another form, celeriac, the root stock and stem are much enlarged. (R.M.W., B S.M.)

CELESTIAL MECHANICS. The term celestial mechanics is applied to that field of astronomical study and research which deals with the motions of two or more bodies in space under the influence of their mutual gravitational attractions. The fundamental elements of the subject are found in the **Newtonian** law of universal gravitation, the laws of motion, and the **Keplerian** laws of planetary motion. In the classical theory we find space of three dimensions treated, with time considered as an independent variable. Within recent years some slight modifications of the classical theory, particularly when the time interval is very long or velocities and accelerations are very high, have become necessary on account of the **Theory of Relativity.** Under the general heading of celestial mechanics we find such problems discussed as the development of the various methods for **orbit** computation, methods for computing **perturbations,** and solutions of the **problem of three bodies.** (W.K.G.)

CELESTIAL NAVIGATION. Navigation, on sea or in the air, by means of observations of celestial objects, is known as celestial navigation.

In the year 1837, Captain Thomas Sumner discovered what has since been known as the **Sumner Line,** and modern celestial navigation may be said to date from that discovery. The methods for determining terrestrial **latitude** (L) and **longitude** (Lo), from **sextant** observations of **altitude** of celestial objects, are briefly described in the article on Sumner Line. In the years that have elapsed since 1837 a great deal of research has been carried out on the theory of the celestial **line of position,** and many methods for calculating the data necessary to plot that line have been developed.

Before discussing these methods, it will be well to understand just what is meant by a celestial line of position, in the modern usage of the term. At any instant any celestial object is directly at the **zenith** for some particular spot on the surface of the earth. This point was formerly known as the subsolar, sublunar, or subastral point, depending upon whether the object observed was the **sun**, the **moon**, or a **planet** or **star**. At present the U. S. Navy uses the term Ground Position (GP) to designate that point, no matter what celestial object is used. The terrestrial coordinates of GP may be expressed in terms of celestial coordinates of the object: the latitude being equal to the **declination** of the object, and the longitude equal to its Greenwich **hour angle.** At present both of these quantities are tabulated for the sun, moon, planets, and **navigator's stars**, in the Nautical **Almanac**, or the Air Almanac, both of which are issued by the Nautical Almanac Office of the U. S. Naval Observatory. These tabulations are given in terms of Greenwich Civil **Time**, and this time is used by all navigators for the recording of the times of sextant observations for altitude.

At the GP the altitude of an object is 90°. If an observer moves out from the GP, in any direction, the altitude of the object decreases in minutes by an amount equivalent to the distance the observer has moved in **nautical miles**. Now assume that an observer obtains the geocentric altitude (h_t) of an object at a given Greenwich Civil Time. From the data given in the Almanac the terrestrial coordinates of the GP may be determined and that point plotted on a sphere representing the earth. Then with this point as center, and with a radius proportional to the number of minutes in $90° - h_t$, a circle is drawn on the sphere. Since the observer is on this circle it is a line of position, by definition of the term.

This method for laying down a line of position on a sphere is very simple in theory, and has been understood for many years. However, to obtain an accuracy in plotting, consistent with the accuracy attainable in sextant observations, requires the use of a sphere of unwieldy dimensions. It is very difficult to draw a line with width less than 0.05″. On the sphere recently proposed for use in the so-called "Spherographic System of Navigation" such a line would have a width equivalent to about 10 miles, and sextant observations are attainable to a much higher accuracy than this.

In modern practice the line of position is drawn on a **Mercator** Chart, plotting sheet, or **small-area plotting sheet** by employing the geometric proposition that a radius of a circle is always perpendicular to an arc. At some particular GCT the altitude (h_s) of a celestial object is obtained with the **sextant** or bubble octant. Then, using the **dead-reckoning** position, or some position close to it which leads to simplified computations, the values of the altitude (h_c) and the **bearing** (Z_n) that the object would have at the assumed position and GCT of observation are computed, or taken from suitable tables. The dead-reckoning, or assumed, position is now set down on the plotting sheet and a line drawn through it in the direction Z_n. This line is a section of the radius of a circle drawn about the GP, which, in reality, is usually off the plotting sheet. Next the difference between the computed and observed altitudes ($h_o - h_t$) is taken and called the "intercept." If the intercept is zero the ship must be on a line of position perpendicular to the bearing line and passing through the plotted position. If the intercept is plus (+) the line of position must pass through a point ($h_o - h_t$) minutes of arc, or nautical miles, away from the GP along the bearing line, and if the intercept is minus (−) the line must be between the plotted position and the GP. In either case the line of position must be perpendicular to the bearing line.

In spite of the fact that the line of position is actually a circle with radius $90° - h_t$ miles, nevertheless, in practically all cases, the line may be drawn as straight. If we assume that the altitude of the object is 80° the value of ($90° - h_t$) is 10° or 600 miles. In this case a straight line 60 miles long, perpendicular to the radius, will differ from the actual circle by less than a mile at its extremities. Accordingly, the assumption of a straight line will not lead to appreciable errors, if the altitude is less than 80° and the drawn line is less than 60 miles long.

Most of the developments in celestial navigation since 1837 have been in improving the methods for obtaining h_o and Z_n. For computation, the so-called "cosine-haversine" formula is used when the tables of H.O. 9 (Bowditch American Practical Navigator) are available. This formula is:

$$\text{hav}\,(90° - h_c) = \text{hav}\,\theta + \text{hav}\,(L - d)$$

$$\text{hav}\,\theta = \cos d \cos L \,\text{hav}\, t$$

in which L is latitude of the DR, or assumed position, d is the declination of the observed object, t is the local hour angle (t = GHA − Lo, with Lo the longitude of the plotted point) and θ is an auxiliary angle. The value of Z_n may be obtained directly from any one of a number of published azimuth tables, or may be computed by means of a variety of formulae (e.g., $\sin Z_s = \sin t \cos d \sec h$ and $Z_n = Z_s \pm 180°$). Various individuals, among them Admiral Marq Saint Hilaire, Admiral Ogura, and Captain De Aquino, have transformed the fundamental equations for solving the **astronomical triangle** to obtain tabular methods for solving for h_o and Z_n. The tables developed by Ageton (H O. 211), or those by Dreisonstok (H.O. 208), were standard for many years in the U. S. Navy. Still more recently, tables by Weems and another by Ageton, have been privately printed. H.O. No. 214 and No. 218 (the former computed by the U.S.W.P.A. and the latter by the British Admiralty Office) tabulate the values of h_c and Z_n for every degree of latitude, every degree of t, and every 30′ of d. For most of the tabular methods and for H.O. 214 and 218, much time may be saved, and very little accuracy sacrificed, by using as a plotted point a position as close as possible to the DR position; but with Latitude an even degree and longitude so selected that (GHA − Lo) will give a value of t some even degree. Such a position is referred to by navigators as an assumed position.

Navigators spend much valuable time in arguing the relative advantages of the different methods for laying down a line of position by celestial navigation. Time, convenience, and personal preference form the topics for debate. Using a DR position and the cosine-haversine method, a line of position can be plotted with from 4 to 5 minutes of computational work. The tables of Bowditch (H O. 9) are all the equipment needed, and this method will yield good results in practically all conditions. The Ageton or Dreisonstok tables require from 2 to 3 minutes of computational work, and the tables are small and convenient. However, to attain the stated speed, an assumed position must be used. H.O. 214 is published in eight large volumes, each covering 10 degrees of latitude, and, using an assumed position, the line may be laid down in about 1 minute. H.O. 218 is published in 18 volumes, each covering 5 degrees of latitude, and using an assumed position, the line may be obtained in slightly less than 1 minute. H.O. 218 has additional advantages over H O. 214 when working with the navigator's stars.

Simple statistical analysis shows that the point on the line of position closest to the dead-reckoning point is the most probable position that can be obtained for the ship from a single observation of altitude. In air navigation this position is referred to as the estimated position (EP). Care must be taken not to confuse this EP with the EP obtained by dead-reckoning navigation in marine navigation. This most probable position, or EP, can be obtained without plotting the line by any of the above methods if the DR position instead of the assumed position is used, since the intercept gives the shortest distance from the DR position to the line.

An example of the use of celestial navigation at sea is given in the following practical case.

During the night of August 18, 1943, the navigating officer of a ship on passage from England to the United States wishes to check the dead-reckoning position of the ship. The two stars Alpheratz and Altair are well placed for observation. When the navigating officer's watch reads 23h 40m 10.0s the sextant altitude of Alpheratz is 50° 34′.3. For the purpose of checking the deviation of the steering compass the bearing of the star is taken by this compass and found to be 121°. At watch reading 23h 46m 15 4s the sextant altitude of Altair is 50° 20′.7. The watch times must be corrected to obtain Greenwich Civil Time (GCT) and the sextant altitudes corrected for instrumental errors, dip, and refraction to obtain the geocentric altitude (h_t). These corrected results are:

Star		GCT	h_t
Alpheratz	Aug. 19	02h 39m 34.0s	52° 27′.4
Altair	Aug. 19	02h 45m 39.4s	50° 13′.8

Using the average of the watch times, the dead-reckoning position of the ship at Aug. 18, 2345 is found as Latitude 43° 24′.6 N and Longitude 48° 27′.4 W. Since the ship is proceeding at only 16 knots and the DR position is probably somewhat in error, this position is used for computing the altitudes and bearings that the stars should have at the GCT's of observation. These values are found to be:

Star	Bearing	h_o
Alpheratz	098°.4	52° 32′.5
Altair	216°.2	50° 07′.4

The intercepts ($h_o - h_t$) are now found: for Alpheratz +5′.1 and Altair −6′.4. These yield two "most probable" positions of the ship, one 5.1 miles from the DR position in the direction 278°.4 (i.e., away from the GP of Alpheratz), and the other 6.4 miles in the direction 216°.2 (i.e., toward the GP of Altair). To determine the fix the DR position is plotted, the bearing lines to the two GP's drawn through it, the intercepts measured off in the proper direction, and the two lines of positions drawn through the intercepts perpendicular to the lines to the GP points The point of intersection of the lines of position is the fix at 2345. The actual plotting, on small area plotting sheet, is shown in Fig. 1. From the figure the fix is found to be in Latitude 43° 20′.7 N and Longitude 48° 35′.2 W. To determine the compass deviation, the difference between the observed compass bearing of Alpheratz and the computed bearing is found to be 121° − 098° = 23°. Since the variation in this region is 26° W, the deviation must be 3° E.

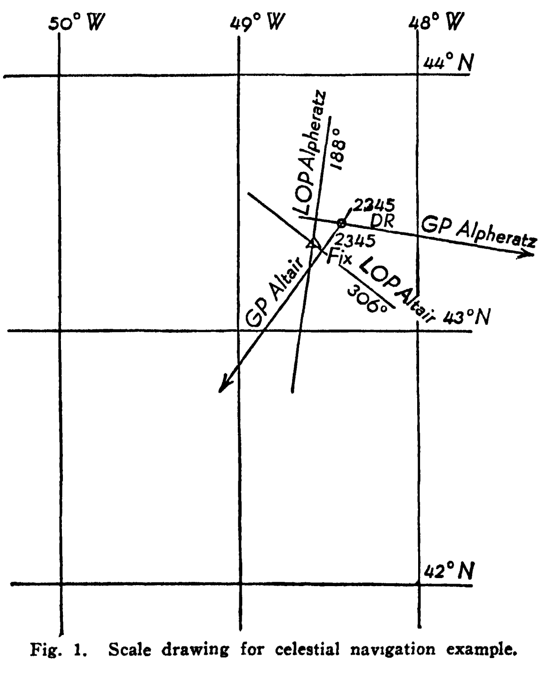


Fig. 1. Scale drawing for celestial navigation example.

Because of the rapid motion of aircraft the most rapid methods for obtaining the data for plotting the line of position must be employed. The bubble octant is used for measuring the altitude of the celestial object. After this is corrected to obtain geocentric altitude, a position is assumed as close as possible to the DR position that is in some even latitude and in such longitude as to make the local hour angle an even degree. Then the data for plotting the line is obtained from the Air Almanac and H.O. 214 and 218. Under the most favorable conditions a rapid computor can have the line of position plotted about 5 minutes after the observation is begun. If two objects are available for observation, about 5 minutes will elapse between the observations, if they are made with maximum accuracy attainable with that instrument. In modern planes a motion of greater than 15 miles between observations is common and the method of running fix (see **Radio Navigation**) must be employed.

Proper selection of stars to be observed will yield data of extreme importance to the pilot and navigator. For example, if the object is nearly ahead or astern of the plane, the line of position will cross the course nearly at right angles and the length of the intercept will provide a check on the ground speed being made good. On the other hand, if the object is in a direction approximately perpendicular to the course the value of the intercept will indicate the accuracy of the wind correction angle.

In many cases altitudes and bearings of celestial objects may be computed in advance of the actual observing. These are known as predetermined altitudes and have many uses in air navigation. If a plane is to depart at a definite time and follow a specified course, the altitudes and bearings to be expected at indicated times may be computed before the plane leaves the ground. The course to be followed is plotted on a chart, the predetermined DR positions for indicated times are marked, and the bearings of the GP of the object are indicated by lines drawn through the DR positions. The precomputed altitudes are geocentric but they may be transformed into those expected to be read on the octant at the specified times, by applying the various corrections with reversed signs. The navigator measures the altitude at an indicated time, obtains the difference between his value and that predicted, and lays off this distance along the drawn bearing line either toward or away from the GP. In this way an EP is determined in a few seconds after the observation is completed, and no computing is required during the flight. The pilot is notified to alter heading and air speed to bring the plane back to schedule. If, due to unforeseen conditions, the plane gets so far off scheduled position that the intercepts are more than 150 miles, the predetermined altitudes must be abandoned and regular celestial navigation adopted.

Under some conditions it may be necessary for a plane to make an accurate landfall (e.g., locate a small island, life raft, etc.) under conditions where celestial navigation must be relied upon. In such cases the use of precomputed altitudes gives great assistance. In such cases an estimated time of arrival (ETA) is obtained. Then, using the latitude and longitude of the landfall, a series of altitudes and bearings of a celestial object is computed. The interval of time between computed values depends somewhat on the rapidity with which the values are changing, but is usually about 10 minutes. The series begins at least half an hour before ETA and extends beyond that value. Two curves are now drawn on graph paper showing altitude and bearing as a function of time. The plotted altitudes are those expected with the octant, i.e., with corrections applied to computed geo-

centric values. If possible an object that is approximately ahead or astern of the plane should be selected. About half an hour before the predicted ETA the pilot alters heading 10° or 15° to the right or left of that predicted for the true course, so that there will be no question as to which side of the landfall he is approaching, and the navigator begins taking altitudes of the object. The navigator plots his observed values, as a function of time of observation, on the same graph as that showing the predetermined values, and obtains a curve of observed values. At the instant that the observed curve intersects that obtained from precomputation the plane must be on a line of position running through the landfall. The bearing of the celestial object at this instant is read off the plotted bearing curve, the line drawn at right angles to this bearing through the destination, and the pilot instructed to alter heading to run down the line.

The "Star Altitude Curves," computed and published in 1940 by the Weems System of Navigation, are, in reality, nothing more or less than predetermined altitudes of selected objects. An appropriate solution of the astronomical triangle may be made to give the latitude and local sidereal time at which a celestial object will be at a specified altitude. On a **Mercator graticule,** using local sidereal time instead of longitude for the invariable coordinate, the positions at which a specified object will have a given altitude may be plotted. A curve drawn through such points will be a curve of equal altitude and, hence, a celestial line of position. In a series of volumes, each covering 10° of latitude and 24 hours of local sidereal time, such equal altitude curves are printed. The printed values of altitude have had the refraction correction applied with reverse sign for standard atmospheric conditions. On each page of the "Star Altitude Curves" three stars are shown, being selected so that they will be favorably situated for observation and give lines of position intersecting at angles of about 60°. The curves are printed for each 10′ of altitude for each star, with the even degrees of altitude indicated by a heavier line with the value of the altitude printed along the line. To use the curves most efficiently the navigator should have a timepiece keeping Greenwich Sidereal Time (GST). Using the proper volume which contains his DR latitude, the navigator then turns to the page covering his local sidereal time (LST), finding this quantity from his DR longitude by the relationship GST − Lo = LST. On the page he will find curves for three stars and he takes sextant altitudes of one or more of these. If his instrument has no appreciable instrumental corrections he may use the observed value directly and the printed curve with the observed altitude is his line of position. Two such lines will provide a fix in terms of latitude and local sidereal time. The longitude of the fix is determined from its local sidereal time by the relationship above Lo = GST − LST. The determination of celestial line of position by means of the Star Altitude Curves is undoubtedly the most rapid of all methods. However, it requires the transportation of several volumes of curves, and the sky must be clear enough to permit the observation of certain particular objects. (W.K.G.)

CELESTIAL SPHERE. The concept of a sphere, on which all of the so-called "fixed stars" are projected, persisted in all descriptions of the structure of the universe from the earliest historical records down through the 17th century. Even in modern times such a concept is very convenient for discussing the common motions of the stars, and the individual motions of the different members of the solar system.

This celestial sphere may be defined as a sphere of infinite radius with the center located within the solar system. The reference frames for all systems of astronomical **spherical coordinates** are established on the celestial sphere.

When projecting the different members of the solar system onto the celestial sphere it becomes necessary to restrict the location of the center to some particular point within the solar system. If the center of the celestial sphere is considered as a point on the surface of the earth we have systems of **apparent coordinates;** with the center at the center of the **earth** we have **geocentric coordinates;** at the center of the sun, **heliocentric coordinates;** at the center of **Jupiter,** Jovicentric coordinates; etc.

Due to the fact that the earth is actually rotating about an axis, the celestial sphere is apparently rotating, as seen from the earth, about an axis parallel to the axis of the earth and with the same angular velocity as the earth, but, of course, in the opposite direction. For purposes of convenience it is customary to refer to this apparent rotation simply as the rotation of the celestial sphere. All systems of spherical coordinates which are established on the sphere, such as the **equatorial, galactic, ecliptic,** etc., rotate with the sphere, while the **horizontal** system apparently remains fixed in space. (W.K.G.)

CELESTITE or CELESTINE. The mineral celestite is composed of **strontium** sulfate, $SrSO_4$, occasionally with **calcium and barium.** It crystallizes in the **orthorhombic** system in tabular or prismatic crystals. More rarely it may be pyramidal or simply fibrous or granular. Two essentially perfect cleavages may be observed, one parallel to the base, the other parallel to the prism. Its fracture is uneven; hardness, 3–3.5; specific gravity, 3.95–3.97; luster, vitreous; color, white, but may be slightly reddish or bluish; transparent to translucent. Celestite may occur with **gypsum** and salt associated with beds of limestone, or by itself in large commercially important veins. It sometimes occurs with sulfur in volcanic localities and is often a gangue mineral in veins of **galena, sphalerite** and similar metallic minerals. In Europe there are many localities for fine crystals, especially in England. In the United States celestite is found in New York, Pennsylvania, West Virginia, Tennessee, Kansas, Colorado, and California. The first celestite described was the delicate blue material from Blair County, Pennsylvania. Its "celestial" tints suggested the name. Celestite resembles barite very strongly. (E.S.C.S.)

CELIAC DISEASE. **Sprue.**

CELL. For the cell as a source of electricity, see **Electrical Cell.** In biology a cell is: 1. Essentially a small chamber, and so applied in the designation of cells in honey-comb, the water cells in the stomach of the camel, and other structures. 2. Also the unit of living matter Early observation of cells was based on plant **tissue** in which the cell walls were the most prominent structure, hence the units were regarded as small compartments. Even after the discovery that these units are small masses of living substance and that the enclosing wall is merely one component which is not always present, the name cell was retained with the new meaning. The first sound expression of the cell theory is credited to Schleiden and Schwann, in 1838 and 1839.

Cells are divided into two principal parts, a nucleus which is usually central or nearly so and an enveloping cytosome, more often known by the name of the material composing it, cytoplasm. Together the nucleus and cytosome make up a living unit which has been named the protoplast or energid; it is enveloped by various membranes which complete the cell. In some cells the nuclear constituents are more numerous, including several separate parts which may be similar and may differ visibly, as in the micronuclei and macronuclei of certain single-celled animals. All of these major parts of the cell are themselves complex.

The cytosome is the part of the cell in which are differentiated the structures by which its special functions are carried out, hence cells are much more varied in cytoplasmic structure and in general form than in their

nuclei. Cells often show a clear peripheral zone of **cytoplasm** called the ectoplasm and an inner mass containing various formed constituents and called endoplasm. The more common of the formed constituents are mentioned in the following paragraphs.

The nucleus differs greatly in form. Although most often spheroidal to slightly elongate it is sometimes of complex shape. It is invested by a delicate nuclear membrane and contains a ground substance called the karyolymph or enchylema in which are two formed components, the linin or supporting network and the chromatin. In the resting cell chromatin is usually dispersed in granules or in a reticular form. It is named for its strong affinity for stains, usually for the basic dyes, which leads it to color readily in preparation for microscopic observation. Since it sometimes takes acid stains the tendency to distinguish the chromatin according to its staining reaction led to the terms oxychromatin and basichromatin, and these led in turn to the suggestion of another collective term, karyotin.

The nucleus also contains knots of chromatin known as karyosomes and other chemically different bodies called nucleoli or plasmosomes. In some cells the two are closely united to form amphinucleoli.

All evidence points to the chromatin as an essential substance which controls the differentiation and constructive action of the cell and as the bearer of hereditary characteristics. The chief evidence of these functions is found in **cell division** and **heredity,** although the removal of nuclei from living cells by microdissection has disclosed the importance of this body in metabolism. Enucleate 1-celled animals continue their activities as long as they have the energy but are unable to assimilate more energy-bearing materials.

The cytoplasm contains an important body known as the central body or centrosome which is active during cell division and is often self-perpetuating. In some cases a structure of similar functions lies within the nucleus. The centrosome contains a central granule or minute rod, sometimes paired, which is called the centriole. This structure is the most common constituent; it is always present, whether or not the surrounding structures appear, and is the active part during cell division. When the investing portion of the centrosome is large it has been called attraction sphere, centrosphere, periplast, and idiosome in various cases but the term centrosome is commonly adopted. The centriole may also be associated with motile appendages of the cell, forming the basal body from which the central filament of a flagellum or cilium arises; it is then called a blepharoplast.

The cytosome of many cells contains differentiated fibrils which are very fine thread-like structures of various functions. Good examples are the myofibrils of muscle cells and the neurofibrils of nerve cells; the former are contractile and the latter may be conductors.

Plastids are relatively large self-perpetuating bodies which are frequent in plant cells but rare in those of animals. The chloroplasts found in the green parts of plants are the most abundant example.

Chondriosomes are specialized bodies of various forms, varying from granular mitochondria to rod-like chondrioconts. Mitochondria sometimes associate in linear groups called chondriomites or in rounded chondriospheres. The functions of all such bodies are uncertain. According to one view they have the power to act upon special chemical constituents of the cytoplasm.

Vacuoles are globular cavities filled with liquid. In the 1-celled animals they contain food and water during digestion, and in the case of the contractile vacuoles the waste products in solution.

The Golgi apparatus is one of the most baffling of all cell structures. Since it is revealed by definite methods of preparation it seems to have definite chemical properties, yet it is extremely diverse and is of uncertain function. It has also been named Golgi bodies, trophospongium, internal reticular apparatus, dictyosomes, and canalicular system.

The Golgi apparatus is either a somewhat reticular structure, usually near the central body and nucleus, or a scattered lot of reticular or granular parts. The separate bodies of which it is composed are of many shapes and have been designated as batonettes, among other terms.

Many cells contain cytoplasmic granules of various kinds whose functions are well understood. They include pigment granules, granules of material for storage, secretory granules which are transformed into the special secretion of the cell during periods of activity, and other special forms.

The membranes surrounding the cytosome in animal cells are thin. They include a delicate plasma-membrane which is regarded as a peripheral layer of the cytoplasm itself, in addition to which there may be an outer cell wall. The latter is secreted by the cell but is not a part of the living cytosome; it is formed of cellulose in many plant cells and in animal cells is represented most strikingly by such highly developed structures as cuticular layers.

Other facts concerning cells are discussed under **Tissues, Cell Division, Gamete,** and **Gametogenesis.** (A.W.L.)

CELL DIVISION. The subdivision of cells is a fundamental expression of the power of reproduction inherent in all living matter. All living cells are capable of dividing to form others or are the products of such division.

Cell division is of two kinds, amitosis and mitosis. The former is an apparently simple elongation, constriction and division of the cell, including its nucleus, and is of relatively rare occurrence. It takes place chiefly in cells of temporary value, as in certain accessory reproductive structures.

Mitosis is a much more complex process of cell division which prevails in the organic world and by its orderly sequence of stages indicates the precise maintenance of essential constituents of the cell. It is conveniently divided into four stages, the prophase, metaphase, anaphase, and telophase.

During the prophase in animal cells the centrioles separate, or if only one is present it divides and the two halves separate, and a series of radiating lines, the astral fibers, forms about each. As these two asters continue to draw apart similar fibers appear between them in the form of a spindle. The whole structure constitutes the achromatic or mitotic figure.

In plant cells (which have no centrioles) the spindle is formed from the transparent protoplasm (karyolymph) of the nucleus and small amounts of cytoplasm on opposite sides of the nucleus. The spindle, in either case, is a polarized gel which, in some unknown way, guides the daughter chromosomes (chromatids) to opposite ends of the cell.

At the same time the chromosomes, which have existed in the resting nucleus as long, thin threads, contract. Each chromosome now appears in the form of two parallel threads (chromatids). These reach their minimum length and maximum width at the end of prophase. The membrane and nucleoli now disappear and a special portion of each chromosome, the centromere (spindle attachment constriction), migrates to the equator of the spindle. This is metaphase.

In the anaphase stage the chromatids, now called chromosomes, migrate to the poles of the spindle The centromere of each chromosome starts first toward the pole so that each chromosome takes the shape of the letter V or J depending upon the location of the centromere.

In the telophase this migration is completed, the cytoplasm constricts and divides, or is separated by the formation of a partition between the two groups of chromosomes, and the two daughter cells undergo a return to the resting form.

Since the differentiation exhibited by chromosomes is

longitudinal, this process of cell division apparently results in the formation of daughter chromosomes exactly equivalent to those of the parent cell, and guarantees to each daughter nucleus a similar assortment of these bodies. With the exception of the centriole the cytoplasmic constituents appear not to be evenly divided.

The type of cell division described here is called somatic mitosis if it involves the diploid number of chromosomes, equational mitosis if the nucleus has the haploid chromosome number. **Meiosis** is a series of two rapidly succeeding mitoses which reduces the diploid to the haploid number and occurs during **gametogenesis** in animals and sporogenesis in the higher plants. (A.W.L., P.A.W.)

CELLULITIS. Diffuse inflammation of the cellular tissues, marked by swelling, redness, heat and tenderness. During this stage of inflammation, **pus** is absent, although an **abscess** is usually surrounded by an area of cellulitis. (R.S.M.)

CELLULOID. **Plastics.**

CELLULOSE. This is a polysaccharide having the formula $(C_6H_{10}O_5)_n$. (See **Carbohydrate.**) It is the substance which composes the greater part of the **cell** walls of plants. **Cotton** fibers are over 90% pure cellulose. Cellulose is insoluble in water, but when dry it soaks up water readily until it is saturated. Water passes readily through the cellulose walls of plant cells. In many cells the cellulose wall is strengthened by the addition of lignin, forming lignocellulose. Being insoluble in water and not affected by digestive juices, cellulose is not digestible and so is available as food only for herbivorous animals (horse, cow, goat, rabbit, etc.) in which the digestive tract is capable of retaining it long enough for digestion by bacteria, or for such insects as the cockroach and termite. Digestion is accomplished in such insects by ameboid protozoa harbored in the digestive tract.

In many cells, especially in those of seeds and in fungi, the walls are formed of hemicellulose, a substance resembling cellulose in many of its properties, but more soluble. Hemicelluloses, of which there are many kinds, are apparently a food reserve of the plant and may be used when need arises. (For further details on cellulose and its chemistry, see **Carbohydrates.**) (R.M.W.)

CELSIUS SCALE. **Temperature Scales.**

CEMENT. Cement is a finely powdered substance which possesses strong adhesive powers, when combined with water. Gypsum plaster (see **Calcium**), common lime, hydraulic limes, Puzzolan, natural and Portland cements are a few of the materials which are used for cementing purposes.

Portland cement, which is the most important of these materials since it is a basic ingredient of concrete, was first manufactured in England in the early part of the nineteenth century. It derived its name from the fact that this newly discovered cement resembled a building stone that was quarried near Portland, England.

There are three fundamental stages in the process of manufacture of Portland cement, namely, (1) preparation of the raw mixture, (2) production of the clinker, (3) preparation of the cement. Whether the process used is wet or dry, the raw materials are selected, analyzed, and mixed so that, after treatment, the product, or clinker, has a desired, narrowly specified composition. A factory analysis of slurry, where the wet process is in use, is as follows: **calcium** oxide 44%, **aluminum** oxide 3.5%, **silicon** oxide 14.5%, **ferric** oxide 3%, **magnesium** oxide 1.6%, loss on ignition about 33% (largely carbon dioxide), showing that the composition of the resulting burned clinker is essentially a calcium aluminosilicate. The system calcium oxide-aluminum oxide-silicon oxide has been determined by Rankin and co-workers. In some places the composition of the rock is practically of the desired composition, and in other places clay and limestone are mixed in the desired proportions.

The raw mixture is heated in a continuously operated, long, almost horizontal, slowly rotated furnace or kiln at a high temperature. The temperature is regulated so that the product consists of sintered but not fused lumps. This is clinker. Too low a temperature causes insufficient sintering, and too high a temperature results in a molten mass or glass, the product in either of these cases being valueless for cement purposes. Clinker is unaffected by water, and may be stored indefinitely without detriment. In 1824, Joseph Aspin, an English bricklayer, took out a patent for the manufacture of an improved cement, which he called Portland cement because, after hardening, it looked like Portland stone, a famous English building stone. The cement thus produced was not what is known as Portland cement as the temperature of burning was not sufficiently high. The value of burning at a temperature sufficiently high to cause incipient fusion was soon afterwards discovered.

In order to obtain the desired setting qualities in the finished cement, there is added to the clinker about 2% of gypsum (calcium sulfate, $CaSO_4 \cdot 2H_2O$), and the mixture is pulverized very finely. For every ton of Portland cement shipped, over two and one-half tons of raw materials *and* cement clinker must be ground to the fineness of flour, and in addition one-half ton of coal or equivalent fuel is burned. Since most of the coal so used is powdered, the total weight of materials to be ground per ton of cement is about 3 tons. Furthermore, some 6 million fire-bricks are used annually in the United States for relining cement kilns.

When Portland cement is mixed with water the product sets in a few hours and hardens over a period of weeks. The initial setting is caused by the interaction of water and tricalcium aluminate ($3CaO \cdot Al_2O_3$), present in the cement, accompanied by the separation of gelatinous hydrated product. The later hardening and the development of cohesive strength are due to the interaction of water and tricalcium silicate ($3CaO \cdot SiO_2$), also present in the cement, accompanied by the separation of gelatinous hydrated product. In each case the gelatinous material surrounds and cements together the individual grains. The hydration of dicalcium silicate ($2CaO \cdot SiO_2$), also present in the cement, proceeds still more slowly than of the above compounds. The ultimate cementing agent is probably gelatinous silica (SiO_2), and it is thought by some that the value of the aluminate lies in its action as a flux in the burning of the clinker.

The analysis of the finished cement made from the above-noted slurry is as follows: calcium oxide 64%, aluminum oxide 5.5%, silicon oxide 21%, ferric oxide 4.5%, magnesium oxide, 2.4%, sulfate 1 6%, loss of ignition about 1% (largely water).

Deductions regarding the mechanism of setting and hardening, and the identity of the substances concerned are the results of extensive studies, involving the use of the microscope in the examination of thin sections, on the individual compounds, the clinker, and the resulting concrete. Elaborate researches have also been conducted to determine the best way of incorporating the ingredients of concrete, the nature of the aggregate (sand, gravel, crushed rock) to be used, and the proportions of cement, water, and aggregate, in order that the resulting concrete, really an artificial rock, shall possess the greatest possible strength.

Special applications of cements and lutes are frequently demanded, as for example in floor covering, in tank lining, and in the closure of joints. The difference between a cement and a lute is that the former sets to a rigid solid mass whereas the latter retains some plasticity so that some movement of the lute is possible

* From Meade's "Portland Cement." † White Portland cement. ‡ Sea-water cement.

without cracking. A lute must have support in order that it be retained in position.

A somewhat crude though convenient classification can be made on the basis of the principal ingredients, thus, (1) Portland cement, (2) high alumina cement, (3) sodium silicate, (4) magnesium oxychloride plus copper powder, (5) litharge or red lead plus glycerol, (6) rubber latex, and (7) synthetic resins. Supplementary materials to be considered are asbestos, white lead, plaster of Paris, sulfur, graphite, sand, pitch, tar, rosin, and boiled linseed oil.

The choice to be made depends upon the kind of material to which the cement or lute must adhere; what it must withstand in the way of acid, base, sulfate, or organic liquid; also what temperature is involved; and finally the matter of resistance to vibration and shock.

Portland and high alumina cements do not withstand acids but are resistant to bases. High alumina cement attains its maximum strength more quickly than Portland, and has the extra advantage that it withstands solutions of sulfates.

Sodium silicate cement does not withstand bases, but is resistant to acids except hydrofluoric. This cement sets to a very rigid solid, so that when subjected to mechanical shock or to temperature change it is liable to crack.

A cement containing 90% magnesium oxychloride and 10% copper powder is strong, resistant to abrasion, and can be bonded to Portland cement.

Litharge or red lead plus glycerol is very commonly used, especially for pipe joints.

Rubber latex cement withstands dilute acids and dilute bases, and adheres well to ceramic materials such as stoneware. This cement remains somewhat pliable, thus resisting mechanical shock and temperature change. Organic liquids in general attack this cement.

Synthetic resin cements withstand hydrochloric acid, dilute nitric acid, dilute sulfuric acid, and dilute bases, and are frequently more resistant to organic liquids than is rubber latex cement. The adherence to ceramic materials is good, and the liability to cracking less than for sodium silicate cement.

As for the miscellaneous ingredients mentioned, some are used as fillers or extenders as in the case of sand, and some are used in their own right as when pitch, tar, rosin, molten sulfur, or packed asbestos can be used. (R.K.S.)

CEMENTATION. In geology, cementation is the process of deposition from solution of mineral matter in the interstices of rocks, and is an important factor in the **consolidation** of coarse-grained **elastic** rocks such as **sandstones** and **conglomerates** or **breccias.** This action is continually going on in the ground water zone, so much so that the term zone of cementation has come into common use.

Cementation may occur in fissures or other openings of the rocks and in time all such spaces will be closed to further deposition or entrance of ground water. In metallurgy, cementation is the process by which one substance is caused to penetrate and change the character of another, by the action of heat, at temperatures below the melting points. (See **Carburizing, Nitriding, Calorizing, Sherardizing, Chromizing,** and **Siliconizing.**) (E.S.C.S., R.H.H.)

CEMENTED CARBIDE TOOLS AND DIES. Extremely hard and abrasive carbides of tungsten, tantalum, titanium, and columbium cemented together by a tough and ductile binding agent, generally cobalt or nickel.

The product is made by the methods of **powder metallurgy**, using a combination of sintering and pressing and a finish grinding operation. In cutting-tool applications cemented carbide tips are inserted in steel holders by brazing in order to conserve the cutting material and provide a tool of suitable shock resistance.

The original material (Carboloy) consists of tungsten carbides in a matrix of cobalt. The cobalt content may be as low as 3% for the hardest varieties and as high as 20% for applications requiring less abrasive hardness but considerably higher strength and shock-resistance.

The die applications include drawing dies for wire, rods, tubing, and special shapes, and dies for extrusion, forming, and deep drawing operations. Such dies are surpassed in hardness only by diamond dies, which have restricted use because of size limitations and cost. Practically all ferrous and non-ferrous alloys can be worked in cemented carbide dies.

As cutting tools, cemented carbides are particularly suited to machining cast iron, aluminum alloys, babbitt, brasses and bronzes, and many non-metallic materials such as hard rubber, Bakelite, asbestos, porcelain, and Masonite. Many of these materials are not readily machined with hardened steel tools because of their abrasiveness. For cutting steel, tantalum carbide and mixed carbide types are used because they resist chip welding and cratering much better than the straight tungsten carbide types. Heat-treated steels of high hardness which are unmachinable even by **high-speed tool steel** can often be machined by cemented carbide tools.

The carbide tools are relatively brittle and must be very rigidly mounted. Best results are obtained with specially built machine tools with capacity to take deep cuts at high cutting speeds.

Other applications of cemented carbides for wear- and corrosion-resistance include lathe centers, gauges, valve stems and seats, sandblast nozzles, and **Brinell hardness** balls. (R.H.H.)

CEMENTITE. Iron carbide, Fe_3C, a compound which is present in nearly all alloys of iron and carbon such as steel and cast iron. It is very hard and brittle and weakly magnetic. At certain elevated temperatures it is dissolved by the iron, forming a **solid solution,** and in the quenching of steels it is essentially retained in solution, but upon **tempering** (reheating to low temperatures) it is precipitated in a very finely divided form, giving structures having high strength and toughness and known as tempered martensite and sorbite. The cementite present in cast irons and steels having appreciable silicon contents can be decomposed at elevated temperatures to iron and carbon in the form of **graphite.** (See **Malleable Cast Iron.**) (R.H.H.)

CENOGENESIS. The development during **evolution** of **adaptations** which persist only during early stages in the life of the individual, giving way finally to the more primitive adult characters. Thus among the insects the **beetle, fly,** or **butterfly** appears to be the original form of the species and the **larva** is a special adaptation which enables the individual to meet special conditions during its growth without giving up the advantages of its adult form. (A.W.L.)

CENOZOIC. The latest major subdivision of the geologic time-scale. The Era of "recent" life, or age of mammals and modern flora. Subdivided, from the base up, into the following Periods: **Paleocene, Eocene, Oligocene, Miocene, Pliocene, Pleistocene, Recent.** The term Tertiary is applied to the first five periods. The Quaternary begins with the Pleistocene. The Era was characterized by: vanishing of **Archaic Mammals** (Eocene); rise of higher mammals (Oligocene); culmination of mammals (Miocene); transformation of the ape-like ancestor into man (Pliocene); periodic glaciation and rise of man (Pleistocene). The Cenozoic Era began 60–70 million years ago. (R.M.F.)

CENTAURUS. (The centaur.) (Map, page 380.) This is a large and brilliant **constellation** of the southern sky, being invisible to observers in North America or Europe. Centaurus has two bright stars which are frequently spoken of as the "southern pointers" since the line through them passes through the southern cross (the constellation Crux). The brighter one of these two (Alpha Centauri) is not only the third brightest star in the entire sky, but is also the nearest bright star. The distance of this star is 4.3 **light years,** the only star thought to be closer than this to the earth being a faint star known as Proxima Centauri. Alpha Centauri is a **double star** and its brighter component is interesting in that it is almost a duplicate of our **sun** in size, temperature, and other physical characteristics. (W.K.G.)

CENTER DRILL. Counterbore.

CENTER GAUGE. A small gauge used for checking lathe center point angles and threading tool points; also used for setting single-point threading tools on a lathe. (H.C.H.)

CENTER HEAD. Measurement.

CENTER OF BUOYANCY. Hydrostatics.

CENTER OF CURVATURE OF A CURVE. Curvature of a Plane Curve.

CENTER OF DISPLACEMENT. Buoyancy.

CENTER OF GRAVITY. Center of Mass.

CENTER OF MASS. This is a more accurate term for what is commonly referred to as the center of gravity. If we imagine a body divided into infinitesimal particles or elements of **mass,** and if each of these elements is acted upon in the same direction, chosen at random, by a force proportional to its mass, it is easily shown that, whatever the direction of this set of parallel forces, their resultant always passes through a certain point, which is the center of mass of the body. Since the weights of the particles of a small body constitute approximately such a system of forces, it has become customary to call this point the center of gravity, though it is in general not strictly correct to do so.

If the body is given a linear acceleration in any direction without rotation, since the **inertia** of each particle is proportional to its mass and acts in direct opposition to the acceleration, the resultant inertia of the whole body acts in a line through the center of mass; which is therefore properly called also the center of inertia.

If any plane is passed through the center of mass of a body, it divides the body into two parts which have the property that their mass **moments** with respect to the plane are equal but of opposite sign. This means that if the mass of each particle is multiplied by its distance from the plane, and the products added, the sum is numerically the same for both parts of the body. This principle may be put into mathematical form and the position of the center of mass calculated therefrom. It may be shown, for example, that the center of mass of a homogeneous right circular cone is on its axis at a distance from the apex equal to $\frac{3}{4}$ of the altitude. For a continuous body of homogeneous material, the center of mass coincides with the **centroid.** (L.D.W.)

CENTER OF PRESSURE, HYDROSTATIC. The point of application of the resultant of all the pressure forces acting upon an exposed area is called the center of pressure. Water and air create pressures which are of importance in phases of engineering. The center of pressure on a horizontal plane immersed in water to a

depth h is the center of the area, that is, the point corresponding to the center of mass of a flat, uniform plate coinciding with the area.

More generally, if a plane surface is completely immersed in a liquid at an angle θ with the horizontal, the center of pressure upon that surface lies at a depth below the top of the liquid, given by the equation $d = \sin\theta \cdot I/M$; in which I is the areal **moment of inertia** of the plane figure with respect to the line of intersection of its plane with the plane of the top of the liquid, and M is the areal **moment** of the figure with respect to the same intersection. For a vertical surface ($\theta = 90°$), $d = I/M$. Thus, in the case of a vertical rectangle whose upper and lower edges are horizontal and at depths h_1 and h_2, and whose width is b, we have $I = b/3(h_2^3 - h_1^3)$, while $M = b/2(h_2^2 - h_1^2)$; hence the depth of the center of pressure is

$$= \frac{2}{3}\frac{h_1^2 + h_1h_2 + h_2^2}{h_1 + h_2}.$$

In particular, if the upper edge is at the top of the liquid, and if the altitude of the rectangle is a, so that $h_1 = 0$ and $h_2 = a$, $d = \frac{2}{3}a$. A rectangular dam 12′ high, and completely filled with water, would thus have a center of pressure at a depth of 8′.

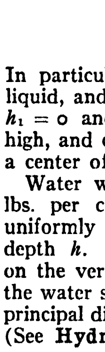
Water which is assumed by engineers to weigh 62.5 lbs. per cu. ft. exerts a horizontal pressure varying uniformly from zero at the water surface to $62.5h$ at a depth h. The total horizontal water pressure acting on the vertical rectangle mentioned above at $\frac{2}{3}a$ below the water surface is $31.25h^2b$ lbs. in which b is the other principal dimension or the vertical width of the rectangle. (See **Hydrostatics.**) (F.T.M., L.D.W.)

CENTER PUNCH. A hand tool with a sharp conical point, used for layout work and locating centers for drilling. (H.C.H.)

CENTERLESS GRINDER. **Grinding.**

CENTIGRADE SCALE. **Temperature Scales.**

CENTIMETER. **C.G.S. System; Electric and Magnetic Units.**



Centipede.

CENTIPEDE. Arthropoda, Chilopoda. Worm-like animals with segmented bodies, a distinct head, and a pair of jointed legs on most segments of the body. They have a pair of **antennae** and the first pair of legs are modified as poison claws for the capture of prey.

The centipedes differ from the nearly related millipedes (**Diplopoda**) in the presence of poison claws, in having only one pair of legs to a segment, and in the more flattened body. Each segment has a dorsal and a ventral plate connected by softer tissue and has the legs joined to the sides of the body. (A.W.L.)

CENTRAL CONICS. **Conic Sections.**

CENTRAL LIMIT THEOREM. The distribution of sample **means** usually approximates a **normal probability function.** The approximation becomes more accurate as the size of the **sample** increases. This is particularly remarkable in that the shape of the distribution of the **population** from which the sample was drawn has little influence over the shape of the distribution of sample means. The necessary and sufficient condition that sample means be distributed normally constitutes the central limit theorem of probability. We shall state a sufficient condition proved by Liapounoff which is extremely general. Let $x_1, x_2, \cdots, x_n$ be independent variables with means zero, possessing absolute third **moments.** $\mu_3^{(1)}, \mu_3^{(2)}, \cdots \mu_3^{(n)}$, respectively. (An absolute third moment is defined as the expected value $|x|^3$.) Let $\sigma^2 = \sigma x_1^2 + \sigma x_2^2 + \cdots + \sigma x_n^2$, σx_i^2 being the **variance** of x_1 and $\alpha_3 = \sum_{i=1}^{n} \mu_3^{(i)}/\sigma^2$. If $\lim_{n\to\infty} \alpha_3$ approaches zero, then the distribution of sample means, $\bar{X}$, approaches a normal distribution. A certain bell-shaped symmetrical probability function called Cauchy's distribution furnishes an example in which the conditions of the central limit theorem are not satisfied, since the Cauchy distribution possesses no mean. The distribution of sample means from a Cauchy distribution reproduces exactly the same Cauchy distribution which does not approach normality no matter how large the size of the sample becomes.

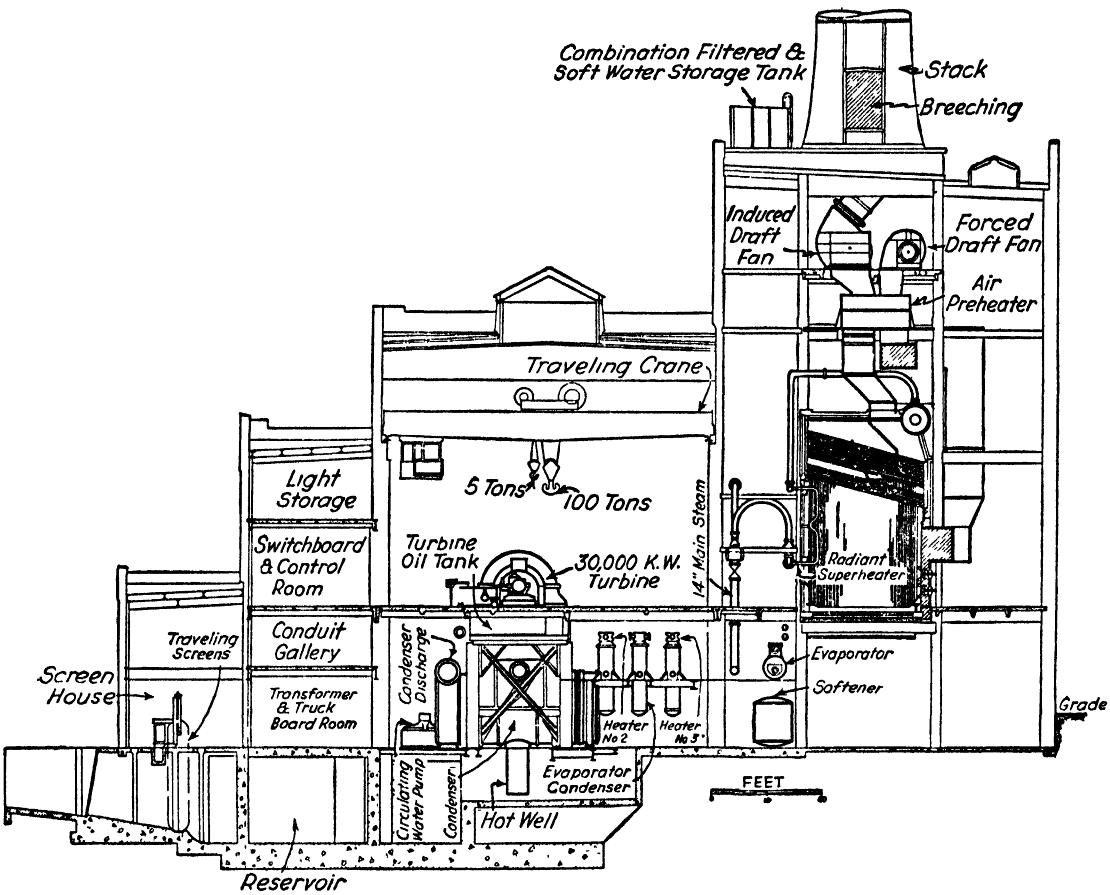
The central limit theorem has many applications. Recently a remainder term has been obtained providing rather accurate estimates of the closeness of the approximation. Similar theorems may be proved for the sample variance when each item is drawn from the same population. (L.A.A.)

CENTRAL LOAD. **Load.**

CENTRAL OFFICE. Telephony.

CENTRAL STATION. A central station is a place where electrical energy is produced from an original source such as **fuel** or water power, and from which the energy is sent out over a network of transmission lines radiating from the station to the load served. The central station is illustrative of the fact that large-scale production is the most economical way of providing electrical energy to the individual consumer, for energy thus produced may usually be sold to the individual for less than he could generate it himself, in spite of the fact that there will be transmission losses on the line between the central station and the customer.

A typical steam central station will consist primarily of a **boiler, turbine,** and **condenser,** the boiler to produce steam, the turbine to utilize the steam for the production of mechanical power, and the condenser to receive the exhaust steam and reduce it to liquid for returning to the boiler, and at the same time provide a vacuum for the more economical operation of the turbine. A **generator** directly connected to the turbine effects conversion of mechanical into electrical energy with a minimum of loss. The boiler-turbine-condenser group must be serviced by auxiliary equipment which might, for clarification, be grouped under two heads,—that auxiliary equipment which might be said to be connected with the flow of air or flue gas in the combustion portion of the plant, and that having to do with the proper conditioning of the condensate produced by the condenser, so that it possesses the requisite heat, pressure, and purity for boiler feed. Included in the first of these groups will be such equipment as **draft fans, stokers, air preheaters,** etc., while in the second group there would be found **feedwater heaters** and **pumps,** feedwater treatment, etc. Between the generator or generators and the outgoing transmission lines, there is contained in the central station no inconsiderable amount of electrical equipment needed for the control and electrical protection of the generators, the supply of auxiliary power, and switching equipment. The accompanying figure is typical of the type of station just described. It shows a boiler room containing the fan and combustion equipment as well as the boiler, a turbine room, which contains little other than the turbines with their generators, but below which will be a basement well filled with condenser and feedwater auxiliaries. Electrical galleries and control rooms on the opposite side of the turbine room from the boiler complete the picture as far as the central station itself is concerned. However, the switching and control as done in the plant are frequently the remote control of high voltage switching



Central station.

equipment which is located in an outdoor type **substation** usually placed adjacent to the plant. (F.T.M.)

CENTRECHINOIDEA. Echinodermata, Echinoidea. An order of sea urchins with a central mouth about which are gills. The commoner sea urchins of North America belong in this order. (A.W.L.)

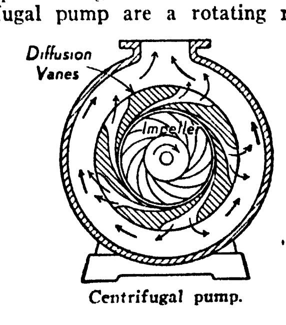
CENTRIFUGAL CASTING. Foundry Practice.

CENTRIFUGAL FORCE. A manifestation of the **inertia** of a body moving in a curved path, the effect being that of a **force** directed radially toward the convex side of the curve. The stresses developed in a rotating rigid body which may cause it to fly asunder, the sensations experienced upon rounding a corner in an automobile, and the action of cream separators, centrifuges, and centrifugal driers, are well known examples.

When a particle moves in a circle of radius r with uniform speed V, it is subject to an **acceleration** toward the center equal to V^2/r. This can be produced only by the application of a **force** in that direction, whose value in absolute units is mV^2/r, m being the mass of the particle. The particle may therefore be regarded as pulling or pushing outward against its constraint with a force of this magnitude. In the case of a rigid body of finite size, it may be shown that the centrifugal force is the same as if the body were concentrated at its **center of mass.**

The centrifugal force involved in the motion of a vehicle around a curve makes desirable the "superelevation" or "banking" of the roadway at an angle dependent upon the curvature and the speed, in order that the wheels of the vehicle may push perpendicularly against the pavement or track. If the speed is V and the radius of the curve is r, then the roadbed should be inclined at an angle s given by the formula: $\tan s = V^2/gr$, where g is the acceleration of gravity. For example, if $V = 40$ ft. per sec. and $r = 1000$ ft., the value of g being 32.15 ft. per sec. per sec., the formula gives $s = 2°\,51'$; which on a standard-gauge railroad track would require the outer rail to be 2.8" above the inner. (L.D.W.)

CENTRIFUGAL PUMP. Although this type of **pump** is now widely used, it is a comparatively new development. The centrifugal pump operates at higher speeds than were easily obtainable before the day of the steam turbine or the electric motor, but with the advent of these high-speed devices, high efficiencies were made possible in the centrifugal pump field, and its advantages, insofar as size, simplicity, and quietness of operation are concerned, have emphasized the possibilities of this type of pump. The figure shows that the essential parts of a centrifugal pump are a rotating member called



Centrifugal pump.

the impeller, and the stationary case surrounding it. The pump action is derived from the conversion of velocity head into pressure head, following the well-known Torricelli formula $V = \sqrt{2gh}$. The liquid to be pumped is let into the pump at the center of the impeller where it is caught in the rotating vanes and caused to take up the angular rotation. This rotation produces a centrifugal force outwardly directed, and since the liquid, say water, is free to move outward between the vanes of the propeller, it does so, and is thrown from the periphery with considerable velocity. If this velocity were converted to pressure in a haphazard fashion accompanied by eddies, whirlpools, etc., a large portion of the velocity head would be lost in heating effect, and the pressure delivered by the pump would be much less than that which may be achieved through proper control of the water leaving the impeller.

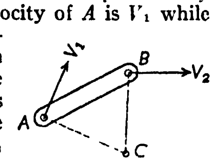
Generally speaking, centrifugal pumps are either of the turbine or the volute type. The illustration pictures a turbine type pump, in that the case is circular and conversion of the velocity to pressure head is accomplished by stationary diffusing guide vanes in the expanding passages of which the water loses its velocity and builds up a pressure. The turbine pump is the more efficient, especially on high heads, but is the more costly. Usually the function of the diffusion vanes is more economically obtained by the use of volute-type casing of proper design. Since the head produced by a centrifugal pump is a function of the square of the water velocity at the periphery of the impeller, it follows that the pressure achieved by a pump is proportional to the square of the speed of rotation and to the square of the impeller diameter. This fact places a practical limitation on the head that can be developed by a single impeller, and pumps for heads higher than practical in a single-stage design are built with several impellers in series; that is, although the impellers are mounted on the same shaft, water passes from the first into the second, etc., each impeller producing an additional increment of pressure. Extremely high heads are possible in multi-stage centrifugal pumps. With few exceptions, all single-stage pumps are the volute type, but builders of high-pressure pumps frequently employ diffusers or guide vanes.

Standard lines of pumps are constructed with impellers of different diameters, and a standard casing. Different capacities are obtained either by changing the impeller diameter or the speed of rotation. At constant speed the head is proportional to the square of the impeller diameter, the capacity is proportional to the impeller diameter, and the power required is proportional to the cube of the impeller diameter. A pump using a given impeller, but having speed variable, will show that the head is proportional to the square of the speed, that the capacity is proportional to the speed, and that the power is proportional to the cube of the speed. The efficiencies of centrifugal pumps vary with the size of the pump and the number of stages; that is, the head pumped against. Very small sizes may have efficiencies as low as 25%. However, for most normal installations the efficiency for small pumps should not be less than 50–60% and for large pumps against a low head may be as much as 80–90%. Modern centrifugal pumps are considerably more efficient than those of twenty or more years ago. A workable theory has been derived for the centrifugal pump, but in its simple form it is incomplete, due to certain indeterminate flow conditions in the propeller. For example, we find that there are friction and eddying of water in the impeller, and shock loss where the water leaves the impeller and enters the case. There is leakage through clearance spaces, and there is disk and bearing friction. (F.T.M.)

CENTRIFUGE. A centrifuge is any machine used to separate liquids from solids which might normally be held by them in suspension, or a liquid of one density from that of another. The operation of the centrifuge is based upon the setting up of **centrifugal force** by high rotative speed, and thus intensifying otherwise minute differences in the weights of two substances. Primarily, a centrifuge consists of a vessel containing the liquid to be centrifuged and the means for whirling that vessel at a high rate of rotation. A simple type of centrifuge is frequently seen in medical offices. In it the container or containers are simply test tubes which are mounted so as to be balanced and revolved in a horizontal plane by means of a geared handwheel. The ordinary cream separator is a centrifuge of a type in which the flow is continuous. The centrifugal force throws the heavier milk into a different container from the lighter cream. This same principle may be used to dry wet or damp textiles, and has a number of other industrial uses. (See **Filtration.**) (F.T.M.)

CENTRIOLE. The small body in the centrosome of a cell, important in **cell division.** (A.W.L.)

CENTRODE. The path of the instantaneous center of a plane figure having plane motion, that is, motion resulting when all points in the figure move in parallel fixed planes, is called the centrode. Any plane body having plane motion which is neither entirely rectilinear nor entirely rotative, but a combination of the two, may be considered at any instant as having rotary motion about a moving point called the instantaneous center of rotation. As shown in the illustration the plane body AB has a motion such that the velocity of A is V_1 while the velocity of B is V_2. At the instant corresponding to the position shown for AB the body must be rotating about a point C, which is located at the intersection of the perpendiculars to V_1 and V_2 dropped from A and B respectively.



C is the instantaneous center of rotation of AB and the centrode is the path traced by the point C while AB is in motion. (C.W.C.)

CENTRODORSAL. The central or basal plate (ossicle) of a free-swimming **crinoid.** (A.W.L.)

CENTROID. The centroid of a given geometrical figure (curve arc, portion of a plane or curved surface, or solid) is the point whose **coordinates** are the **mean values** of the coordinates of the points of the given figure; it is independent of the choice of axes. The centroid of a geometrical figure corresponds to the center of gravity (or center of mass) of a material body of similar form.

For a plane curve arc, the centroid is given by formulae:

$$\bar{x} = \frac{\int_a^b x\,ds}{L}, \quad \bar{y} = \frac{\int_a^b y\,ds}{L},$$

$$ds = \sqrt{1 + \left(\frac{dy}{dx}\right)^2} \cdot dx = \sqrt{1 + \left(\frac{dx}{dy}\right)^2} \cdot dy,$$

where L is the length of the arc.

For a plane area, the centroid is given by:

$$\bar{x} = \frac{\iint_A x\,dS}{A}, \quad \bar{y} = \frac{\iint_A y\,dS}{A},$$

where A is the area of the given region.

For a solid, the centroid is given by:

$$\bar{x} = \frac{\iiint_V x\,dV}{V}, \quad \bar{y} = \frac{\iiint_V y\,dV}{V}, \quad \bar{z} = \frac{\iiint_V z\,dV}{V},$$

where V is the volume of the given region. (L.L.S.)

CENTROSOME. A small body in the cell. (A.W.L.)

CENTROSPHERE. A specialized structure in the cell. (A.W.L.)

CENTRUM. **Earthquakes.**

CENTURY PLANT. **Agave americana,** the Maguey or American aloe, is often called the century plant. It has a very short thick stem which bears a rosette of thick fleshy leaves, in which are stored food reserves. Each year the plant adds three or four leaves to the rosette. After a period varying from 5 to many years (perhaps a century) vegetative growth ceases and flowering occurs. A gigantic terminal flower bud is formed and grows rapidly. It bears many flowers. After the fruit has formed the whole plant dies. It is this habit of bearing flowers only after a prolonged period of vegetative growth that has given this plant the common name, century plant. It is widely grown in cultivation, and seldom flowers under such conditions. The plant propagates vegetatively by means of suckers which grow out from the base of the stem. (R.M.W.)

CEPHALASPIS. **Fossil Fishes.**

CEPHALIC GLAND. A structure lying in the anterior end of nemertine worms. (A.W.L.)

CEPHALOCHORDATA. Chordata. A subphylum containing a number of species of small marine animals called lancelets. From one of the included genera the name Amphioxus has become common in laboratories to designate any lancelet, although the animals so designated more commonly belong to the genus *Branchiostoma.*

The lancelets differ from the other groups of lower **chordates** in their fish-like form. They are small, usually from 1½ to rather more than 2″ long, and taper toward both ends; the body is laterally compressed. Like other members of the phylum they have a dorsal nerve cord, below it a stiffening longitudinal rod, the **notochord,** and a **pharynx** perforated by many slits. A depression called the vestibule leads to the mouth. It is surrounded by a circlet of slender **cirri.** **Cilia** about the mouth carry food particles into the alimentary tract where they are caught by the mucus in a ventral groove, the endostyle, carried forward, upward, and then back to the intestine, all by ciliary action.

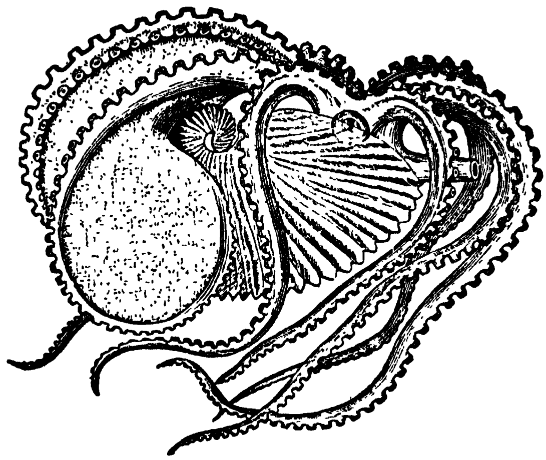
The lancelets are important to the evolutionist in several ways. Since they swim actively in the tides and bury themselves in the sand at other times, taking their food like sessile animals, they illustrate possible ancestral conditions for the tunicates on the one hand and the fishes on the other. The peculiar food-concentrating mechanism described above is also important; it occurs in larval lampreys and provides one of the few well-marked evidences of relationship between the vertebrates and lower chordates.

Although of great scientific interest the lancelets have been of little economic importance. They are caught in large numbers for food by the Chinese. (A.W.L.)

CEPHALONT. An attached form of certain parasitic 1-celled animals (**Protozoa, Sporozoa**). (A.W.L.)

CEPHALOPODA. A class of the phylum **Mollusca** containing the **squids, cuttlefish, octopus** or devilfish, and **nautilus.** The class is relatively small but it includes the most highly developed of unsegmented invertebrates and is of some economic importance. All of the species are marine.

These mollusks are distinguished by the following characteristics: 1. The head bears a pair of large eyes which are of the camera type like those of man although they differ fundamentally in structure. 2. The mouth is surrounded by a group of tentacles provided with many cup-like suckers and sometimes with hooks. 3. The **mantle** cavity opens to the exterior by a broad entrance and by a slender tube, the funnel or siphon; by forcing jets of water from the cavity through the siphon the animal propels itself through the water in the opposite direction. 4. The foot is modified to form the siphon and possibly the tentacles. 5. The mouth is provided with a sharp beak superficially like that of a bird of prey. 6. Some species have an ink-sac from which a dark fluid is discharged for concealment. 7. The shell is internal or absent in most species.



Female *Argonauta argo.* (*Lull, Organic Evolution, after Claus-Sedgwick. Macmillan & Co., Ltd.*)

Squids and cuttlefish are eaten by some peoples. The latter species furnishes the cuttlebone so familiar in bird cages and the true sepia pigment. Squids are of importance in North America chiefly as bait in the fisheries of the Atlantic Coast. The octopus has been credited with amazing feats of destruction at sea which are probably entirely imaginary. Giant squids are known to occur, with a total length of 50′, and are more likely subjects of these tales, but there is no satisfactory evidence that even these creatures are greatly to be feared by man.

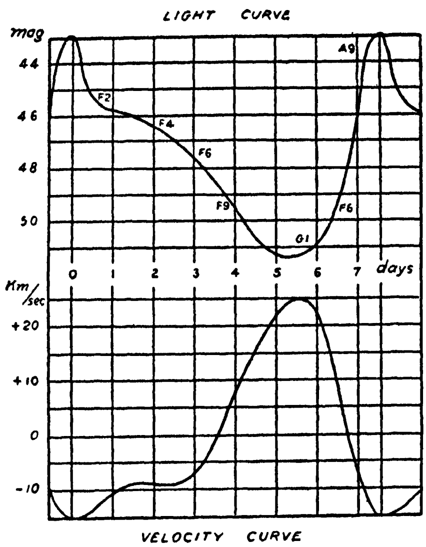
The class is divided into two orders. The first was abundant in the past but is now almost extinct.

- Order Tetrabranchiata. Shell external, spiral, and divided into a series of chambers of increasing size, in the last of which the animal lives. Once abundant, now limited to four known species in the genus *Nautilus.*
- Order Dibranchiata. Shell internal or lacking and usually straight. The **squids** and **cuttlefishes** have ten tentacles, the **octopus** or devilfish and the **argonaut** or paper nautilus only eight. (See also **Invertebrate Paleontology.**) (A.W.L.)

CEPHALOTHORAX. The anterior body region of **spiders, crustaceans** and some other **arthropods,** consisting of the compactly associated head and thorax. (A.W.L.)

CEPHEID. Examination of the curve in the article on **variable stars,** showing the number of variable stars of different periods, indicates that there are two groups of periodic variables with periods less than 50 days. The term Cepheid, derived from the typical short period variable **δ Cephei,** is applied to all variables with periods under 50 days. The group with periods less than one day are frequently referred to as cluster-type variables, because of the fact that they are most numerous in globular star **clusters,** while for purposes of differentiation Cepheids with periods greater than 5 days are referred to as "typical Cepheids."

The mean **light curve** of a typical Cepheid, together with the mean **velocity curve** plotted on the same time scale, is shown in the accompanying figure. (Light and



Light and velocity curves of W. Sagittarii. (*Curtiss in Lick Observatory Bulletins.*)

velocity curves of W. Sagittarii.) The general characteristics of the curve are typical for all Cepheids with the rapid rise to maximum followed by a more gradual decline to minimum. The descending portion of the curve is characterized in typical Cepheids by certain irregularities.

With the change in brightness of a Cepheid there is also a change in **spectral type**, the stars being somewhat bluer at maximum as shown by the letters along the light curve. Also correlated with change in brightness of the typical Cepheid is a change in **radial velocity**, with the star approaching the observer at maximum and receding at minimum.

The cause of the variability of the Cepheids has been a mystery ever since the study of this type of variables was begun. For many years it was believed, because of the variations in radial velocity, that the objects were **spectroscopic binaries**. Shapley, Eddington, and others have conclusively shown that this cannot be the true explanation, and have proposed an alternative hypothesis that the stars are pulsating. On the basis of this theory the star when approaching its minimum is relatively cool and is contracting under the influence of gravitational attraction. As the mass of gas contracts the increased pressure in the interior produces a rise of temperature and eventually outward pressure due to high temperature overbalances the gravitational force and the star suddenly expands. The sudden expansion produces cooling until gravitation overbalances the outward force and contraction takes place again. Since at the time of expansion, the outer surface will be approaching the observer and also the temperature is higher than during the contracting stage, we find the correlations between brightness, spectral type, and radial velocity all accounted for on this theory. Many details remain to be accounted for before we are entitled to say that the problem of Cepheid variation is completely solved, but the pulsation hypothesis certainly seems to be a step toward the final solution.

In the course of the study of typical Cepheids in the Small Magellanic cloud, Miss Leavitt, of the Harvard College Observatory, found a direct correlation between the average **magnitude** of the Cepheids and the period of variation. Since all variables in the cloud are at approximately the same distance from the earth, it appeared that the period of variation was directly correlated with intrinsic brightness or, in other words, with average **absolute magnitude.** Shapley, after an exhaustive study of numerous Cepheids with known distances and hence known average absolute magnitudes, was able to show that the correlation between period and luminosity was apparently characteristic of all Cepheids and, by plotting period against average absolute magnitude, obtained what is commonly known as the period-luminosity curve. After this curve is established, it is possible to determine the absolute magnitude of any Cepheid, no matter how distant, by simply determining the period. With the absolute magnitude and the apparent magnitude known, the calculation of the distance of the Cepheid is a relatively easy task. The period-luminosity relationship has been extended to the cluster type Cepheids and, while there is still some question as to the "zero point" of the various curves, it has served a very valuable purpose in determining distances of globular clusters. Cepheid variables are also found in distant extragalactic **nebulae** and hence they may be used to determine distances of objects outside of our own **galactic system.** For this reason the Cepheids have been referred to as "the measuring rods of the universe." The explanation of the period-luminosity relation has not yet been found, but it may very probably be connected with the **mass-luminosity** relationship found by Eddington and others for all stars. (W.K.G.)

CEPHEUS. (Map, page 380.) This **constellation** is particularly interesting because it contains the remarkable **variable star** Delta Cephei. This star is the typical **Cepheid** variable, a class of stars which is most valuable in providing a measuring rod for probing the remote regions of space. (W.K.G.)

CERAMICS. The requisite raw material for making ceramic materials is clay. Clay is essentially an **aluminosilicic acid** ($H_2Al_2Si_2O_8$), containing more or less foreign matter such as (1) ferric oxide (Fe_2O_3), which contributes the reddish color frequently associated with clay, (2) **silica** (SiO_2) as sand, (3) **calcium** carbonate ($CaCO_3$) as **limestone.** Since clay is formed by the decomposition of igneous rocks, followed by transportation of the fine particles by running water and later deposition of these particles by sedimentation when the flow of water diminishes in speed, the quality of clays shows a wide range. When clay is wet it is plastic and can be shaped according to the desire and skill of the operator. The shape is retained on drying, and subsequent heating produces a coherent, hard mass, which suffers in the process more or less shrinkage and deformation depending upon the composition of the raw materials, and the method and temperature of treatment. Common bricks are made of crude materials without careful regulation of the conditions of treatment.

Bricks and plain clay products possess an earthy surface and fracture, are porous, and the strength depends upon the materials and treatment. Porcelain, on the other hand, possesses a glass-like or vitreous surface and fracture, and is not porous. Porcelain is made by mixing with the clay some powdered feldspar mineral potassium aluminosilicate ($KAlSi_3O_8$ approximately). At the temperature of firing, feldspar undergoes a gradual change from the crystalline to the glassy state, the rate depending upon the time of heating and the temperature to which it is subjected. The fusion point of **feldspar** is of the order of 1300° C., whereas that of **kaolin** (pure clay) is of the order of 1700° C. Subjection of the porcelain raw material to the latter temperature would result in the formation of a glass. But when the temperature used is below the melting point of the clay portion and about the melting point of the feldspar, the latter produces a glass cement which binds together the particles of the former. When ground **quartz** (SiO_2) is added to the original clay mixture the shrinkage of the material in the processes of drying and firing

is reduced, the resistance to deformation during firing is increased, and the temperature coefficient of expansion of the product is affected.

The range of clay, feldspar, and quartz, as to the ratios in the mixture and as to individual composition of each (see tables 1 and 2), as well as the available range of temperature of firing makes possible the production of products of a wide variety of physical structure. There has been proposed an arbitrary line of demarcation, namely that the unglazed product, such as has been described, which absorbs not more than 1% of its weight upon and after immersion in water, shall be termed porcelain, otherwise it shall be called earthenware. Such a non-porous material as porcelain which includes chinaware is also distinctly translucent in thicknesses of a few millimeters, whilst earthenware is non-translucent and somewhat porous.

Materials that are to be glazed are dipped in a slip (the mixture of raw materials and water), dried, and refired. The glaze mixture is made up so that its fusion temperature is lower than that of the body of the ware, and the firing temperature is such that a surface of glass is formed over the body of the ware.

Designs and colors may be placed, as is commonly done, on the glaze and refired, or, as less commonly and more recently with fine effect, directly on the body under the glaze, in which case the glaze when produced covers and protects both the body of the ware and the decoration.

The range of ceramic products is great, as is illustrated by the following materials, namely, common bricks, hollow bricks, pipes, tiles, terra cotta, fire-bricks resistant to high temperatures, stoneware, crockery, earthenware, porcelain, chinaware. Fire-bricks are in-

TABLE 1

Raw Materials	Chinaware	Earthenware
Total clay, usually blended	46 5%	50 5%
Feldspar	15	13 5
Quartz	36	36
Dolomite	2 5	.....
Porosity average	0 5	8

TABLE 2
TABLE SHOWING ANALYSES OF CERTAIN CERAMIC RAW MATERIALS

	Silica	Alumina	Lime	Magnesia	Iron Oxides	Soda	Potash
	%	%	%	%	%	%	%
Kaolin	58	29	0 2	0 3	1	1	1
Fire clay	61	26	0 3	0 4	1	1	1

dispensable in high-temperature industries that use electric furnaces, blast furnaces, reverberatory furnaces, converters, that produce ceramics, Portland cement, glass, and in the high-temperature furnaces for producing steam and for subjecting coal to destructive distillation. (R.K.S.)

CERARGYRITE (Horn Silver). The mineral cerargyrite, silver chloride, AgCl, crystallizes in the isometric system but is usually massive appearing like wax or horn, hence the name horn silver. It has no cleavage, is highly sectile, yielding bright surfaces; hardness, 1–1.5; specific gravity, 5.55; luster, resinous to adamantine; color, gray, white to colorless, may be blue, violet-brown after exposure to light; transparent to translucent. Cerargyrite is largely a secondary mineral, usually associated with other silver minerals as well as with compounds of **lead, zinc,** and **copper.** Saxony and the Harz Mountains are European localities. The Broken Hill district of New South Wales is a well-known occurrence, but probably the most important deposits are found in Atacama, Chile. It is found also in Bolivia and Mexico. In the United States cerargyrite comes from Colorado, Idaho, Utah, Nevada, Arizona and New Mexico. The name cerargyrite is derived from the Greek meaning horn and silver. (E.S.C.S.)

CERATA. Projecting respiratory organs found on the upper surface of the body in some of the marine **snails.** (A.W.L.)

CERATITE. **Invertebrate Paleontology.**

CERCARIA. A larval form of the **flukes** (parasitic flatworms) with a compact body and slender tail (A W.L.)

CERCOPOD. Slender projections at the posterior end of the body in certain crustaceans (Phyllopoda). (A.W.L.)

CERCUS, CERCI ANALES. Paired jointed appendages at the posterior end of the body in some **insects.** (A.W.L.)

CEREALS. **Grass Family.**

CEREBELLUM. A division of the vertebrate **brain.** (A.W.L.)

CEREBRAL GANGLION. 1. The simple brain of many invertebrates. 2. Either member of the anterior pair of **ganglia** in the molluscan nervous system. 3. The upper posterior component of the brain of **cephalopod mollusks.** (A.W.L.)

CEREBRAL TUBE. A ciliated tube associated with the brain in certain marine worms (Sipunculids). (A.W.L.)

CEREBROSPINAL FLUID. The fluid which circulates in the ventricles of the brain and in the subarachnoid spaces of the brain and spinal cord. (See **Brain.**) Its function is the mechanical protection of the brain and cord; possibly it takes part in metabolic activities, although there is no proof of this. In appearance, the fluid is normally water clear; it contains sodium chloride in slightly higher amounts than in blood; its glucose content is approximately half that of blood, and protein is present only in minute quantities. There are 0 to 8 cells per cu. mm., all lymphocytes. Lumbar puncture, the insertion of a needle between the lumbar vertebrae and the withdrawal of a small amount of fluid for examination, is a safe and valuable diagnostic procedure in diseases of the central nervous system. In **meningitis,** the fluid is cultured, and examined directly for **bacteria.** Alterations in cell count, pressure, and chemistry are helpful in the differential diagnosis of tumors as well as infections. (D.M.H.)

CEREBRUM. A region of the vertebrate **brain.** (A.W.L.)

CERES. **Asteroid.**

CERIUM. Symbol: Ce. Atomic number: 58 Atomic weight: 140.13. Density: 6.8. Melting point: 640° C.

Types of compounds: Ce_2O_3, white cerous oxide; CeO_2, pale yellow ceric oxide. Color of salts: cerous, colorless; ceric, yellow. Discovered by Berzelius and Hisinger in 1803. (**Isotopes**: page 290.)

Cerium occurs in **monazite** sand, a cerium phosphate (50%–75% ceria), **cerite**, a basic silicate of **calcium** and **iron** (50%–70%), and **allanite**, a hydrated silicate (up to 50%).

The cerium sub-group of the rare earth metals (see **Yttrium**) consists of the elements scandium, lanthanum, cerium, praseodymium, neodymium, illinium, samarium, europium, and gadolinium, all of whose potassium sulfate compounds are relatively insoluble in water. Cerium is the most abundant of the rare earth metals, and each member of the cerium sub-group, except samarium, is said to be more abundant than yttrium. Cerium metal is prepared by electrolysis of the fused chloride, and is used as a pyrophoric alloy (70% Ce with iron) in gas and tobacco lighters.

Nitrates: Cerous nitrate ($Ce(NO_3)_3 \cdot 6H_2O$), pink to colorless crystals, soluble; ceric nitrate ($Ce(NO_3)_4$), reddish-yellow crystals, soluble.

Oxide: Cerous oxide (Ce_2O_3), grayish-green powder; ceric oxide (CeO_2), pale yellow powder, soluble in sulfuric acid, used in gas mantles (1% CeO_2 with thorium oxide), and in coloring glass and ceramic ware.

Sulfates: Cerous sulfate ($Ce_2(SO_4)_3$), green to pink, depending upon the amount of water of crystallization; ceric sulfate ($Ce(SO_4)_2$), yellow to orange-red solid, soluble, used in **sulfuric acid** solution as a strong oxidizing agent. (R.K.S.)

CERUMEN. The waxy secretion that collects in the external ear. (R.S.M.)

CERUSSITE. The mineral cerussite, **lead** carbonate, $PbCO_3$, is **orthorhombic** with tabular, prismatic and pyramidal crystals, with twinned forms very common. If not in crystal aggregates it may occur in granular or compact masses. Cerussite is very brittle with a conchoidal fracture; hardness, 3–3.5; specific gravity, 6.46–6.57 (a heavy mineral); luster, adamantine but may be vitreous to resinous, pearly or even submetallic. Its color is variable, white to gray, grayish-black or blue or green, transparent to translucent.

Cerussite is of secondary origin being found associated with other lead minerals, and is widely distributed. There are many European and American localities. Fine crystals have been obtained from Phoenixville, Pennsylvania; Joplin, Missouri; Leadville, Colorado; Pima County, Arizona, and Dona Ana County, New Mexico. It is an ore of lead, and frequently carries values of **silver**. Derived from the Latin *cerussa*, white lead. (E.S.C.S.)

CERVALCES. **Pleistocene.**

CERVICAL GROOVE. A groove marking the boundary between head and thorax in the **crustaceans.** (A.W.L.)

CERVIX. Any narrow or neck-line portion of an organ. The term is usually used in reference to the narrow end of the **uterus** that projects into the **vagina.** (R.S.M., D.M.H.)

CESIUM. Symbol: Cs. Atomic number: 55. Atomic weight: 132.91. Density: 1.87. Melting point: 28.5° C. Boiling point: 670° C. No isotope, but of single atomic form: 133.

Cesium is a silver-white, very soft metal, possibly the softest of all the metals; tarnishes instantly on exposure to air, soon igniting spontaneously with flame to form oxide; preserved under kerosene; reacts vigorously with water forming cesium hydroxide solution and hydrogen gas. Discovered by Bunsen and Kirchhoff in 1860 by means of the spectroscope.

Cesium occurs in **pollucite** (cesium aluminosilicate, 35% Cs_2O), **lepidolite** (lithium aluminosilicate), and traces in certain mineral waters. The localities having the highest known concentrations of cesium are in Maine, Black Hills, South Dakota, and the island of Elba. Cesium salts may be recovered from the mother liquor upon crystallization of lithium salts, but are separable from rubidium salts with great difficulty. Cesium metal is obtained (1) by **electrolysis** of fused cesium **barium** cyanide mixture out of contact with air, (2) by distillation of cesium chloride with **calcium** metal.

Chloride: Cesium chloride (CsCl), white deliquescent solid, melting point 646° C., soluble.

Hydroxide: Cesium hydroxide (CsOH), white, deliquescent solid, melting point 272° C., soluble.

Oxide: Cesium oxide (Cs_2O), red solid, by heating cesium metal in oxygen or dry air, reactive with water to form soluble cesium hydroxide; several higher and lower oxides have been reported.

Other soluble salts: Cesium sulfate (Cs_2SO_4); cesium nitrate ($CsNO_3$); cesium carbonate (Cs_2CO_3); cesium fluosilicate (Cs_2SiF_6).

Slightly soluble salts: Cesium perchlorate ($CsClO_4$), insoluble in alcohol; cesium chloroplatinate (Cs_2PtCl_6); cesium permanganate ($CsMnO_4$).

Volatile cesium salts, such as the chloride, color the bunsen flame violet. (R.K.S.)

CESTIDA. An order of ctenophores (**Ctenophora**). (A.W.L.)

CESTODA, CESTOIDEA. The tapeworms. A class of the phylum **Platyhelminthes.** The tapeworms, like other members of the phylum, are flat-bodied The body consists of two regions, a head or scolex usually bearing hooks, suckers, or both, and a strobila which, in all but the simplest species, is formed of a series of segments called proglottids. Tapeworms are parasitic in vertebrates.

In addition to the characters mentioned, tapeworms are distinguished by a complex life cycle. The adults live in the intestine of the host, absorbing food through the wall of the body since they have no alimentary tract, and produce a long succession of **proglottids** which break off as they mature and pass out with the faeces of the host, break off and remain in the intestine, or mature while still attached to the worm. They are reproductive bodies containing the organs of both sexes, rarely those of only one. The fertilized egg becomes a simple **embryo** with six hooks called the onchosphere. In this stage it is taken into the alimentary tract of a new host, migrates into the blood vessels, and after drifting along the blood stream lodges in some part of the body and develops into another form, usually vesicular, called the bladder worm. In this stage it remains inactive unless the tissue containing it is eaten by another animal, in which case it attaches itself to the intestinal wall of the new host and develops into an adult tapeworm.

Tapeworms are among the important parasites of man. Some of these species live in hogs and cattle and become established in man as the result of eating imperfectly cooked meat and one of the most dangerous species is found in the dog during its adult stage and in domestic animals and man in the bladder worm stage. The elimination of tapeworms from the human body requires the careful attention of a physician.

The tapeworms are classified as follows:

Subclass Cestodaria. Parasitic in fishes as adults and in **annelid** worms and **mollusks** in the early stages No distinct **scolex** and no segments
- Order Amphilinidea. Species of leaf-like form.
- Order Gyrocotylidea. Leaf-like, with a projecting organ of attachment at the posterior end.

Subclass Cestodes. Usually segmented. **Proglottids** with organs of both sexes.

Order Tetraphyllidea. Scolex without retractile projections (proboscides), with four suckers or bothria. Parasitic in cold-blooded vertebrates.
Order Tetrarhynchidea. Scolex with proboscides. Parasitic in fishes.
Order Pseudophyllidea. No proboscides; only two suckers or bothria. In vertebrates of all classes.
Order Cyclophyllidea. Four suckers and usually hooks. Body elongate, with distinct segments, often numerous. Principally in warm-blooded vertebrates. (A.W.L.)

CETACEA. The whales, dolphins, porpoises and related mammals. An order, now replaced by two, **Odontoceti** and **Mystacoceti**, for the toothed whales and whalebone whales, respectively. (A.W.L.)

CETANE NUMBER. **Ignition Quality.**

C.G.S. SYSTEM. The **metric system** of physical units is based primarily on the standard **meter** and the standard **kilogram**, preserved at Sèvres. Experience has shown, however, that the usage of physics is often better served by founding its measures upon the centimeter and the **gram** (along with the mean solar second), rather than to use the meter and the kilogram directly. The "c.g.s." (centimeter-gram-second) system is the basis of nearly all present-day physical measurement, except in certain fields still commonly employing English units. (See **M.K.S. System.**)

Following are listed the c.g.s. units of certain familiar magnitudes, together with their dimensional makeup in terms of the fundamental units of the system (see **Physical Magnitudes and Physical Equations**):

Magnitude	C.G.S. Unit	Dimensions
Area	Square centimeter	cm^2
Volume	Cubic centimeter	$cm.^3$
Speed	Centimeter per second	$cm.\ sec.^{-1}$
Acceleration	Centimeter per second per second	$cm.\ sec.^{-2}$
Momentum	Gram-centimeter per second	$g.\ cm.\ sec^{-1}$
Force	Dyne	$g.\ cm.\ sec.^{-2}$
Torque	Dyne-centimeter	$g.\ cm.^2\ sec^{-2}$
Pressure	Barye or Bar	$g.\ cm.^{-1}\ sec.^{-2}$
Energy and Work	Erg	$g.\ cm^2\ sec.^{-2}$
Power	Erg per second	$g.\ cm.^2\ sec.^{-3}$

(L.D.W.)

CHABAZITE. The mineral chabazite is a member of that group of hydrous **silicates**, the **zeolites**, and corresponds to the formula $CaAl_2Si_6O_{16} \cdot 8H_2O$ with sodium sometimes replacing a part of the **calcium**. **Potassium, barium** and **strontium** may be present in very small amounts. Chabazite is **hexagonal**, usually in rhombohedrons that tend to resemble cubes. It has a rhombohedral cleavage; is brittle; hardness 4–5; specific gravity 2.08–2.16; luster vitreous; color white to flesh-red; streak white; translucent to transparent. Chabazite is found in the amydaloidal cavities of **basalts** often associated with other zeolites. It is occasionally found in such crystalline rocks as **syenites, gneisses** and **schists**. Chabazite is a rather common zeolite, being found in many localities in Europe. In the United States it occurs in the Triassic traps of New Jersey and Maryland. The **Triassic** lavas of Nova Scotia have yielded fine specimens. The name chabazite is derived from the Greek word meaning a precious stone. (E.S.C.S.)

CHACHALACA. **Guan.**

CHACMA. Mammalia, Primates. The largest of the baboons, *Papio porcarius*, resident in the extreme southern part of Africa. Also called the pig-tailed baboon. (A.W.L.)

CHAETA. A slender pointed structure secreted by cells of the **integument** in many invertebrates, such as the **annelids**. A **seta.** (A.W.L.)

CHAETOGNATHA. The arrow-worms, a group of small marine animals sometimes included in the phylum Annelida but now more often regarded as a separate phylum.

Arrow-worms are usually elongate transparent animals. They have two or three pairs of horizontal fins, one forming a caudal fin at the end of the body. The head bears a pair of eyes and a group of spine-like jaws which give the name to the phylum. The alimentary tract runs through the body as a straight tube to an anus near the caudal end. The body cavity is divided into three chambers by two transverse septa. Although the phylum includes only about 30 species, arrow-worms are found from the surface to great depths and in all of the oceans. (A.W.L.)

CHAETONOTOIDEA. **An order of rotifers.** (A.W.L.)

CHAETOPODA. A division of the **annelid** worms including the forms which have setae set in pockets in the integument. The **coelom** is well developed and is at least partially divided into **metameric** chambers, and the external segmentation of the body is also metameric. Most of the marine annelids such as the lobworm and **clam worm** and the **earthworms** and freshwater annelids are included here. The **leeches** and a few more primitive worms make up the rest of the phylum.

By some authorities this division is called a class and is divided into two orders:

Order **Polychaeta.** Free-swimming and sedentary worms, mostly marine, with lobed appendages (**parapodia**) and many **setae.** Usually a head with sensory organs. This group is sometimes regarded as a class and is then divided into two orders, the Errantia with similar body segments, most species free-swimming or burrowing, and the Sedentaria with specialized body regions, living in tubes in the bottom of the ocean, or between the tides.
Order **Oligochaeta.** Fresh-water and terrestrial worms with few setae and with neither parapodia nor sensory appendages. The earthworms are common examples. Sometimes ranked as a class. (A.W.L.)

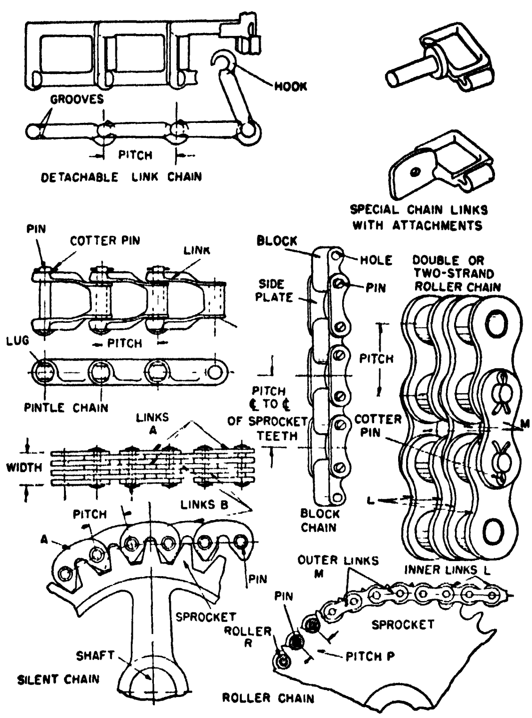
CHAFER. Insecta, Coleoptera. A name applied to certain plant-eating **beetles,** including the rose chafer of the United States. The adults of this species are sometimes a troublesome pest on small fruits, especially grapes. They damage the fruit itself. Spraying with **lead** arsenate is recommended for their control. (A.W.L.)

CHAFFINCH. Aves, Passeriformes. Birds (**Aves**) of several species found in Europe and western Asia. The brambling is a member of the same genus, *Fringilla.* (A.W.L.)

CHAIN. A flexible connector composed of metal links, used for hoisting or for power transmission. *Coil chain* is used for hoisting and haulage, and consists of oblong links of circular sections, usually of welded wrought iron or steel. Coil chain with a stud or bridge across the center of the coil is preferred to plain coil chain in some instances, since the studs tend to prevent stretching and kinking.

Chain used for power transmission is shown in the figure. *Detachable link chain* is used for low-speed and light-load power transmission, and for conveyors and elevators of moderate capacity and length. The links can be easily detached and replaced, as illustrated. *Pintle chain* is from two to four times as strong as detachable link chain and can be used with the same sprockets.

Both types of chain are usually made up of malleable iron unmachined links. They can be supplied with integral pin, plate, or scraper attachments.

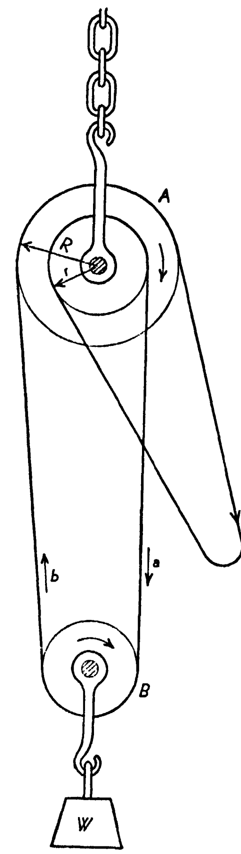


Steel block, roller, and silent chains are used where an exact speed ratio is desired and the center distance of the shafts is too large for gearing. *Block chain* is used for comparatively slow speeds and consists of blocks linked together by connecting links and pins. *Roller chain* consists of alternate links L and M held by connecting pins which are fastened by cotters. The pins also serve to carry the rollers which bear on the sprocket teeth. Roller chain can transmit more power than block chain and can operate at chain velocities up to 1200 ft. per min. For power requirements too great for single chains, double-, triple-, or quadruple-strand roller chains may be employed.

Silent chain is composed of alternate flat steel links A and B connected by pins. The links have straight faces in contact with the sprocket, and rotate slightly on the pins as the chain bends around the sprocket. Silent chain is used for heavy loads at speeds up to 1600 ft. or more per min. The silent chain is not actually quiet in operation but is much less noisy than other types of chain in use at the time of its adoption.

The speed ratio of a power chain depends upon the numbers of teeth in the driving and driven sprocket wheels; velocity ratios up to 7:1 are satisfactorily employed. Short-center drives with high ratios are usually more economical if fine-pitch chain is employed, while narrow large-pitch chain is cheaper for low-ratio long-center drives. (H.C.H.)

CHAIN BLOCK. Chains and sheaves may be employed in combination to produce an unusually powerful lifting mechanism. The best of these is the differential chain block, the action of which is explained in connection with the accompanying diagram. The mechanism consists of two sheaves, A and B, A being double sheave having diameters R and r. It will be shown that the multiplying power of this mechanism depends upon the ratio of these diameters. If they are equal, the pull P will not move the weight, and the efficiency of the mechanism will be 0%, but the theoretical mechanical advantage is infinity. A slight difference in radii will produce a very large lifting effort, although the efficiency may still be very low. The sheaves are made with link pockets so that the chain fits nicely into the circumference, and is restrained from slipping. Furthermore, the chain is endless, and the mechanism is self-locking by virtue of the friction intentionally allowed on the journals.



Chain block hoist.

In explanation of the chain block, if the pull P revolves sheave A one revolution, the vertical chain at a is lowered through a distance to $2\pi r$, while the side b is raised the distance $2\pi R$. The net vertical displacement of the sheave B is $\pi(R - r)$ upward. With no friction considered, the work of lifting W through this distance must be equal to the work done by the pull P moving through $2\pi R$. Solving this equation for advantage W/P,

$$\frac{W}{P} = \frac{2R}{R - r}.$$

Applying the mechanical efficiency e to this equation, the actual mechanical advantage is

$$\frac{W}{P} = \frac{2Re}{R - r}.$$

These chain blocks are built in different sizes for hoisting loads from ¼ ton to 3 or 4 tons, by hand. On account of the self-locking feature depending on friction, the average mechanical efficiency of this device is only about 30%. (F.T.M.)

CHALCEDONY. Chalcedony is one of the cryptocrystalline varieties of the mineral **quartz,** having a waxy luster. It may be semi-transparent or translucent and is usually white to gray or grayish-blue or some shade of brown, sometimes nearly black. Other shades have been given different names. A clear red chalcedony is known as **carnelian** or **sard;** a green variety colored by nickel oxide is called **chrysoprase. Prase** is a dull green. **Plasma** is a bright to emerald-green chalcedony which sometimes is found with small spots of **jasper** resembling blood drops; it is then referred to as **blood stone** or **heliotrope.** The term chalcedony is derived from the Greek word meaning Chalkedon, a town in Asia Minor. (E.S.C.S.)

CHALCID FLY. Insecta, Hymenoptera. Minute in**sects** of many species, usually shining or metallic and with very simple wings showing a single vein. A few feed on plants, and the fig insects, *Blastophaga psenes*, are essential for the fertilization of Smyrna figs, but most species are parasitic on other insects during their larval life. The host species are attacked by these parasites in all stages of metamorphosis, including the egg.

A few species are important pests in wheat but the chief economic importance of the group lies in the destruction of other pests by the parasitic species. It is difficult to estimate the importance of such natural checks. (A.W.L.)

CHALCOCITE (COPPER GLANCE). The mineral chalcocite is **cuprous sulfide,** Cu_2S, crystallizing in the **orthorhombic** system, often in pseudo-**hexagonal** forms. Above a temperature of 91° C. chalcocite changes into an **isometric** form. It has conchoidal fracture; hardness 2.5–3; specific gravity, 5.5–5.8; metallic luster; color dark gray to blackish-gray, frequently with bluish-green tarnish. Chalcocite is of widespread occurrence and a valuable copper ore. It seems in some cases to be definitely secondary in origin, in other cases primary. It may have been formed from bornite by the action of alkaline solutions. It sometimes carries valuable amounts of silver.

Among the many European localities might be mentioned Cornwall, England, the Ural Mountains, and Rumania. It occurs also in the French Congo, South West Africa, Peru, Mexico, and Alaska. In the United States it is found at Bristol, Connecticut, in fine crystals, Montana, Tennessee, Arizona, Nevada, and California.

The word chalcocite is derived from the Greek word meaning copper. (E.S.C.S.)

CHALCOPYRITE (COPPER PYRITES). The mineral chalcopyrite is a **sulfide of copper** and **iron** corresponding to the formula $CuFeS_2$. Its **tetragonal** crystals are often complex with repeated twinning; massive chalcopyrite is common. It has an uneven fracture; is brittle; hardness, 3.5–4; specific gravity, 4.1–4.3; luster, metallic; color, brass-yellow, may be iridescent from tarnish; streak, greenish-black; opaque. Chalcopyrite is the most common copper-bearing mineral known and it is the most important ore of copper. It is a primary mineral in many igneous rocks and from it a host of secondary copper minerals have been derived. Among the many localities where fine specimens of this mineral have been obtained might be mentioned: Freiburg, Saxony; Alsace; Rio Tinto, Spain; Cornwall, England; Australia; Chile, Peru, and Bolivia, South America; and in the United States, Ellenville, New York; Chester County, Pennsylvania; Joplin, Missouri; Gilpin County, Colorado, Arizona, Montana, Utah, Nevada, California, New Mexico and Tennessee. In Canada there are notable deposits of chalcopyrite in the Provinces of British Columbia, Ontario, and Quebec. The name chalcopyrite is derived from the Greek word meaning copper, and the word pyrites. (E.S.C.S.)

CHALK. Chalk is a soft, porous **limestone** of white, grayish-white or buff color made up of the minute shells of **foraminifera** and fragments of **cocospheres.** It occurs extensively in England and France and less so in the United States. (E.S.C.S.)

CHALYBITE. Siderite.

CHAMELEON. Reptilia, Sauria. Any member of several genera of lizard-like **reptiles** of very peculiar form, occurring in Africa, the Oriental region, and about the Mediterranean. They are arboreal species with grasping feet, a crested head, and a long extensile tongue with a clubbed sticky tip which is used to catch insects. They are able to change color readily. The most common genus is *Chamaeleon.*

The little lizard commonly sold at street fairs in the United States is not a true chameleon but is more closely related to the iguanas. (A.W.L.)

CHAMOIS. Mammalia, Artiodactyla. A goat-like European **antelope,** ***Rupicapra tragus,*** found in the forests of mountainous regions and to a limited extent under alpine conditions. Noted for its agility. (A.W.L.)

CHANCRE. The first manifestation of **syphilis.** A chancre is a single, hard, elevated sore, which appears on the penis, vagina or external genitalia 3 to 4 weeks after exposure. Occasionally an extragenital lesion—usually on the lips—occurs. The lesion lasts 6–8 weeks. Although its clinical characteristics are striking, a positive diagnosis of syphilis cannot be made unless the spirochetes can be demonstrated in the secretions of the sore by examination with a dark-field microscope. Early diagnosis is extremely important because the earlier treatment is begun, the better is the prognosis. (See **Syphilis.**) (D.M.H.)

CHANCROID. A veneral disease characterized by multiple soft **ulcers** on the genitalia. It is sometimes called soft **chancre,** in contrast to hard chancre of **syphilis.** The ulcers of chancroid contain the causative organism, Ducrey's bacillus. The regional lymph nodes in the groin may form **buboes,** ulcerate, and discharge pus Treatment is local, plus sulfonamides orally. (D.M.H.)

CHANNEL. Compression Member; Tension Member; Gauge Line.

CHANNEL, FREQUENCY. This term denotes the band of frequencies which is associated with a single unit of intelligence in a communications system. Thus it applies to the band of frequencies radiated by a broadcast station, or to the band of frequencies which must be handled by a carrier system to handle a single conversation. In the various systems the application of intelligence to a given frequency will generate certain other frequencies which are then associated with the original in some manner to convey the intelligence to the receiver. This band of frequencies then determines the response characteristics which the receiver (or other units of the system) must have for satisfactory results. Thus in conventional broadcasting the various stations use channels about 10 kc. wide; in frequency modulation the present channel is about 200 kc.; in television it is 5 or 6 megacycles; in carrier telephony it is only about 3 kc. (L.R.Q.)

CHAPARRAL. The name applied to a **plant association** occurring over wide areas in western North America and composed of a mixed population of low-growing shrubs. Some stands of chaparral are dense; others are open. Chaparral is usually found between a lower zone of **sagebrush** or grassland and an upper zone of woodland or forest. This association is found principally in the foothills of the Coast Ranges and Sierra Nevada in California, of the southern Rocky Mountains, and other ranges in Utah and Arizona. Some types of chaparral, such as that occurring on the Coast Ranges of southern California, are composed largely of evergreen shrubs; others, such as that occurring in the southern Rocky Mountains, largely of deciduous shrubs. (B.S.M.)

CHARACTERISTIC CURVE. Gamma, Exposure-Density Relationship.

CHARACTERISTIC EQUATIONS. A class of equations connecting those variables, such as temperature, pressure, and volume, which define the physical condition of a given substance and are called variables of state.

The **ideal gas law** and the **Boyle-Charles** law represent approximately the behavior of all gases, but if one wishes to be accurate, some modification of these must be sought which will take account of the differences between individual gases. The best known characteristic equation for gases is that of van der Waals Using the same notation as for the ideal gas law, this may be written

$$\left(p + \frac{a}{v^2}\right)(v - b) = RT.$$

(Here, however, the volume is not in liters but is in terms of the volume of the same body of gas at standard temperature and pressure; and the pressure is in atmospheres) a and b are constants characteristic of the gas in question

They are very small; if they were zero we should have the ideal gas law. Following are their approximate values for certain gases:

Gas	a	b
Ammonia	0.00831	0.00165
Helium	0.00007	0.00106
Hydrogen	0.00049	0.00119
Nitrogen	0.00277	0.00175
Oxygen	0.00271	0.00142

Clausius modified van der Waals' equation as follows:

$$\left(p + \frac{a}{T(v+c)^2}\right)(v - b) = RT,$$

employing three empirical constants a, b, c; while the equation of Dieterici has an exponential factor:

$$p \cdot e^{\frac{a}{RTv}} \cdot (v - b) = RT.$$

None of these equations represents the behavior of all gases equally well.

Beattie and Bridgman have proposed a characteristic equation for fluids in general, as follows:

$$pv^2 = RT\left(1 - \frac{c}{vT^3}\right)\left[v + B\left(1 - \frac{b}{v}\right)\right] - A\left(1 - \frac{a}{v}\right),$$

in which a, b, c, R, A, and B are empirical constants to be determined for each fluid. (L.D.W.)

CHARACTERISTIC IMPEDANCE. This is the **impedance** which a transmission **line** would present at its input terminals if the line were infinitely long. If, instead of the line being actually infinite in length, it is finite and is terminated by an impedance equal its characteristic impedance it will behave, as far as the input is concerned, as if it were infinite. This means that there will be no reflected electrical wave, with the attendant losses, etc., at the terminal point. In electrical circuits this is an extremely important consideration as reflection means some energy which would otherwise go to the load is reflected back down the line to cause losses on the line, objectionably high voltages, echo effects and other undesired conditions. When a line is terminated in the characteristic impedance it is said to be matched, or the load matches the line. While not always attainable it is a condition highly desirable. (L.R.Q.)

CHARACTERISTIC OF A COMMON LOGARITHM. **Logarithms.**

CHARACTERISTIC SPEED. Specific Speed.

CHARACTERISTIC TEMPERATURE. **Dulong and Petit's Law of Specific Heats.**

CHARADRIIFORMES. A large order of shore and wading birds (**Aves**) including the **gulls, terns, auks, puffins, plovers, sandpipers, snipes,** and many others. (A.W.L.)

CHARGE-MASS RATIO. This term refers to the relationship between the electric charge of a particle and its mass, so important in the physics of **electrons, ions,** and other electrified bodies of molecular order.

The earliest information on the subject followed from the researches of Faraday on electrochemical equivalents. From his results it appears that in the electrolysis of chlorine, for example, one **coulomb** of **negative** electricity is carried by 0.00037 gram of this element, and hence that the carriers or ions have a charge-**mass** ratio of about 2700 coulombs or 8.1×10^{12} electrostatic units of electricity to the gram. Similarly, one coulomb of positive electricity is carried by 0.0000104 gram of hydrogen, which gives about 95,700 coulombs or 2.87×10^{14} e.s.u. to the gram for hydrogen ions. This is 35 times the ratio for chlorine ions. But the atomic masses of hydrogen and chlorine are in the ratio 1:35, which means that if the carriers are atoms, the charge per carrier is the same for both elements. Bivalent elements, on the other hand, carry twice this charge per ion.

When J. J. Thomson applied a magnetic field to a stream of hydrogen **canal rays,** and then neutralized the resulting deflection by means of an electric field, he was able to calculate the charge-mass ratio of these particles from the curvature of the magnetically deflected stream and the values of the two field intensities. This he found to be either 95,700 coulombs per gram as in the electrolysis of hydrogen, or ½ that value, which indicated that some of the ions were atoms and some were molecules carrying the same charge as the atoms. But when a similar test was applied to the **cathode rays** in a **Crookes tube,** the ratio was found to be about 5.303×10^{17} e.s.u. per gram, or 1850 times that for hydrogen atoms, whatever the nature of the cathode. We know now that this enormous difference is one of mass, not of charge; and that these experiments were the first direct revelation of the identity of the **electron,** which has a mass only 1/1850 of that of the hydrogen atom. (L.D.W.)

CHARLES' LAW. Although the coefficients of expansion of different solids or of different liquids are notably different, the coefficients of expansion of all gases are nearly the same, namely, about 1/273 of the volume at 0° C. per centigrade degree. The law, stated by Charles in 1787 and independently by Gay-Lussac in 1802 (hence sometimes called Gay-Lussac's law) is not strictly true. Regnault obtained the following values of the volume coefficient for various gases:

Air	0.0036706
Hydrogen	0.0036613
Carbon dioxide	0.0037099
Sulfur dioxide	0.0039028
Carbon monoxide	0.0036688
Nitrous oxide	0.0037195
Cyanogen	0.0038767

None of these is far from 1/273 = 0.003663, which is therefore commonly taken as the expansion coefficient for gases; especially as the value for hydrogen, commonly used in the standard gas thermometer, is very near it. If the pressure as well as the volume is allowed to vary, the behavior of the ideal gas must be expressed by the **Boyle-Charles law** or the **ideal gas law.** (L.D.W.)

CHARLIER COEFFICIENT OF DISTURBANCY. The Charlier coefficient of disturbancy, C, is defined as

$$C = 100\frac{\sqrt{\sigma^2 - spq}}{sp}$$

where s is the number of trials, p is the **probability** of success in a single trial, and σ^2 is the **variance** of the distribution of the number of successes. (L.A.A.)

CHARNOCKITE. Charnockite is a granular variety of **hypersthene granite** which was first described from the gravestone of Job Charnock, who founded the city of Calcutta, India, whence the derivation of the name charnockite. (E.S.C.S.)

CHARR. Pisces, Teleostei. *Salvelinus.* A lake fish (**Pisces**) of the British Isles, related to the trout. (A.W.L.)

CHART. A chart is a **map** drawn to show those details which are of primary importance to navigators. Since the **rhumb line** and **great circle** are curves on the surface of the earth most used by navigators, most charts

are drawn on either the **Mercator** or **Great Circle projections** in order that these curves may appear as straight lines. A few charts of harbors or small islands will be found drawn on the **polyconic projection.** Within recent years the **Lambert projection** has superseded all others for use by air navigators.

Charts differ from maps by emphasizing those features and details which are of importance in **navigation** and in omitting many features of interest to the general public. The parallels of **latitude** and meridians of **longitude** are always clearly marked, and **compass** "roses," frequently showing both true and magnetic **directions,** are printed on the charts in convenient places. The coast pilot is interested in such things as prominent landmarks to be watched for when approaching from seaward, such as high mountains not too far inland, church spires, Coast Guard stations, light houses, light ships, beacons, **buoys, range marks, soundings,** etc. The off-shore navigator is interested in the depth of water, character of the sea bottom, compass variation, prevailing currents, positions of **radio aids,** etc. Aviation charts emphasize those surface features of most importance to the air navigator such as **contour lines,** heights of mountains, rivers, railroads, power transmission lines, water towers, radio stations, radio beams, airports, etc.

Before using any chart the navigator must study the legend carefully to determine such things as the date of issue, interval of contours, units of soundings, and similar data. No navigator, either over land or sea, should ever use a map published for commercial purposes. To do so is to court disaster since, for example, railroad companies frequently publish maps showing their lines as straight for long distances, and moving towns from their correct locations so that they appear to be on the straight route. (W.K.G.)

CHAT. Aves, Passeriformes. Birds (**Aves**) of several species, usually designated by a compounded word, as the stonechat and whinchat of Europe, the yellow-breasted chat of North America (*Icteria virens*), and several North African species. The European wheatear and hedge warbler are also chats. (A.W.L.)

CHATOYANCY. Cat's-Eye.

CHATTERER. Aves, Passeriformes. South and Central American birds (**Aves**) making up the family Cotingidae. They are quite varied, some with strangely formed plumage and some beautifully colored. The family includes the umbrella bird, **bell-birds, cotingas,** manakins, and **cocks-of-the-rock.** A single species, the xantus becard, *Platypsaris aglalae,* enters the United States near the Mexican border.

These birds are near the flycatchers. (A.W.L.)

CHATTER MARKS. Moon-shaped scratches or gouges on the bed rock which are supposed to be caused by the "chattering" action of angular boulders which are carried in the bottom of a glacier. (R.M.F.)

CHAULMOOGRA OIL. *Teraktogenos (Hydnocarpus) Kurzii.* Flacourtiaceae. Chaulmoogra oil is expressed from the seeds of a tall tree native to the jungles of northern Burma. The tree has a smooth light-brown bark, large leathery evergreen leaves and inconspicuous flowers. The fruits have a soft hairy surface and contain several large seeds.

The oil has long been known and used in Burma and other Malasian countries in the treatment of various skin afflictions and **leprosy,** often with very favorable results. Modern science has advanced this problem by expressing the oil and purifying it, so that the painful effects associated with the use of the crude oil have been eliminated. Thus, ethyl **esters** of the fatty acids in the oil are prepared. This product is given by intramuscular injection into the buttocks. Treatment is continued over long periods of time—3–5 years or more, with intervening periods of rest without treatment. (R.M.W., R.S.M.)

CHEEK. The lateral wall of the oral cavity. (A.W.L.)

CHEETAH, CHETAH, CHITA. Mammalia, Carnivora. A large **cat** found in Africa and India. It is marked by its slender build and is tawny with black spots, thus somewhat resembling the leopards. The species is known as the hunting leopard and has been tamed for use in the chase. (A.W.L.)

CHELA. A form of grasping appendage found in **lobsters, crabs** and other **arthropods.** The large pincers of these species are the most familiar examples.

All chelate appendages have the next to the last segment prolonged into a process against which the terminal segment works to form a forceps-like organ. (A.W.L.)

CHELICERAE. The first pair of appendages in **spiders** and related animals. They are associated with the mouth and are formed for chewing and in some cases for grasping, as in the **scorpions.** (A.W.L.)

CHELIPED. An appendage of the **thorax** formed for grasping, in the **crustaceans.** The chela or pincher of the lobster and crayfish. (A.W.L.)

CHELLEAN. Paleontology of Man.

CHELONIA. Testudinata; Fossil Reptiles.

CHEMICAL CHANGES. The chemical composition of a substance is subject to various changes under various conditions, depending upon (1) the nature of the individual substance, (2) the nature of other substances present, and (3) the conditions. The vast majority of reactions take place between two substances—occasionally one substance only, and sometimes three or more different substances. There are many cases where simple contact of the substances is sufficient to bring about the chemical change, e.g., the rusting of iron in oxygen. In many other cases, the change is not spontaneous, but must be induced, frequently by raising the temperature, as in the burning of fuels. The conditions that are considered important and fundamental are (1) temperature, (2) pressure, (3) medium, if any, (4) catalyzer, if any, (5) electric direct current, (6) light. In a given reaction, the change in composition of the substance or substances involved is inherently connected with a change in energy. Thermal, electrical or light energy of a certain potential or intensity and in definite amounts, is requisite to initiate and carry on the reaction, and thermal, electrical or light energy of definite amount is liberated or consumed in the reaction. Every reaction, properly speaking, has both a matter and an energy aspect While the energy aspect is frequently neglected directly, the conditions must always be in accord with the energy demand, even if apparently not considered. (See **Thermochemistry; Electrochemistry; Photochemistry.**) Chemical changes require consideration of three topics, namely, I. Natural rate of chemical reactions, II. Acceleration of the natural rate in the presence of a catalyzer, and III. The end-point of chemical reactions.

I. *Natural Rate of Chemical Reactions.* Various factors operate to affect the rate of chemical reactions. By natural rate is understood the rate of a reaction in the absence of a **catalyzer.** Excluding electrochemical and photochemical reactions, and giving attention to thermochemical reactions only, there are four factors or conditions to be considered, namely, (1) concentration of constituents, (2) temperature, and (3) pressure—important where a **gas** is involved, (4) nature of the medium, if any.

(1) Relation between concentration of reactants and rate of reaction. The rate of a given reaction, at constant temperature and pressure under stated conditions of concentration of the reacting substances, is quantitatively expressible by a velocity constant, which is the fraction of the substances transformed in a unit of time. Many reactions occur instantaneously—true for most reactions in solution in inorganic chemistry—and many others are complicated by subsidiary reactions, so that the velocity constant is measurable in comparatively few cases. The principle, however, holds as stated, whether or not the desired value can be ascertained experimentally.

A simple reaction that was studied by Wilhelmy (1850), and since then by various investigators, is the transformation (hydrolysis) of **sucrose** ($C_{12}H_{22}O_{11}$) in water solution into **glucose** ($C_6H_{12}O_6$, a polyhydroxy aldehyde) plus **fructose** ($C_6H_{12}O_6$, a polyhydroxy ketone), which proceeds at a measurable, steady rate in the presence of acid (**hydrogen ion**). The rate of reaction at any instant is found to be proportional to the amount of sucrose present at that instant.

When a dilute water solution of an **ester**, such as methyl acetate, is similarly hydrolyzed in the presence of hydrogen ion, the reaction is of the same type. And this statement also applies to the decay of **radioactive** elements. One of the important radioactive constants is the period, that is, the time required for the decay of one-half of the element present at a given instant.

The preceding cases are instances of monomolecular reactions—in the case of sucrose and of methyl acetate the concentration of water, when it is in large excess, remains constant throughout the reaction. Only in monomolecular reactions is the velocity constant independent of the initial concentration.

The rate of bimolecular and higher types of reactions depends upon the concentration of each reactant, and is specific in each case.

When a reaction involves two different phases, that is, when the system is not homogeneous but heterogeneous, as in reactions between a solid phase, such as **zinc** or **calcium** carbonate, and a liquid phase, such as **hydrochloric acid** solution, the rate of reaction involves consideration of (1) the area of the surface of contact of the solid with the solution, and (2) the rate of diffusion from the surface of the solid, as well as (3) the concentration of hydrogen ion of the acid solution.

When the rate of a chemical process is dependent upon (1) two or more *consecutive* reactions, the observed rate is limited by the rate of the slowest reaction in the series, (2) two or more *concurrent* reactions, the products are in the same ratio at any instant only when the reactions themselves are of the same rate.

(2) Relation between temperature of reactants and rate of reaction. The rate of chemical reaction is increased two or three times for a rise in temperature of 10° C. The rate of decay of radioactive elements has been found to be unaffected by temperatures from the lowest to the highest attainable.

(3) Relation between pressure of reactants, if gaseous, and rate of reaction. Since pressure changes amount to concentration changes in such systems, the behavior is as described above under concentration.

(4) Relation between nature of the medium and rate of reaction. Very slight changes in the nature of the medium greatly affect the rate of a chemical reaction, but attempts to relate any physical property of a solvent with the effect observed on the rate of a given reaction appear to have proved unsuccessful.

Summarizing, the rates of chemical reactions are subject to highly specific influences in each case, as has been abundantly demonstrated by experimental investigations, and recognized in numerous legal battles in chemical patent suits.

II. *Acceleration of the Natural Rate of Chemical Reactions* in the presence of a positive or negative catalyzer (see **Catalysis**). When, in the presence of a given substance, the natural rate of a chemical reaction is changed, either increased or decreased, the given substance is called a catalyzer. Examples are numerous. 1. When a gas-lighter of the type known as **platinum** black, the active part of which consists of very finely divided platinum, is held in a stream of **hydrogen** or city gas, the gas is ignited in air. Platinum is a catalyzer for this reaction, and causes ignition to take place at a temperature much lower than by subjecting to fire. 2. The changing of **sulfur dioxide** into **sulfur trioxide** is accomplished by passing a mixture of sulfur dioxide and air (one-fifth oxygen) over asbestos coated with finely divided platinum. The temperature required is much lower by the use of platinum catalyzer than without its use. 3. Solutions of sulfites are subject to oxidation to sulfates by oxygen upon allowing to stand in air. The addition of sugar or glycerol retards the speed of this reaction. These substances act in this case as negative catalyzers. 4. The combination of **nitrogen** and **hydrogen** gases under high pressure to form **ammonia** gas is accomplished at a lower temperature in the presence of a catalyzer than in its absence, thus increasing the yield of ammonia (see **Equilibrium**). One of the catalyzers is composed of **iron**, intimately mixed with 1% **aluminum** oxide and 1% **potassium** oxide. Iron is a catalyzer for this reaction, but is more active as such in the presence of aluminum oxide and potassium oxide, which are spoken of as promoters, a sort of catalyzer of a catalyzer. 5. The hydrogenation of liquid fatty oils and of oleic acid is conducted in the presence of finely divided nickel as a catalyzer. 6. **Enzymes** are very specific catalyzers, "the most selective and delicate of all known catalysts (Hilditch)," at ordinary temperatures, say 25° to 30° C. Dextro-glucose is converted into ethyl **alcohol** in the presence of the enzyme (zymase) of yeast, and ethyl alcohol into **acetic acid** (vinegar) in the presence of the enzyme of *Mycoderma aceti*. 7. **Nitric acid** reacts slowly with copper metal, but the rate of reaction is accelerated more and more as nitrogen tetroxide (catalyzer) is formed in the solution. This is an example of autocatalysis, wherein the reaction brings about the formation of its own catalyzer. 8. **Arsenic**-containing substances are extreme negative catalyzers, called inhibitors or poisons, of platinum catalyzer.

When the catalyzer is a solid substance, the greatest difficulty in use is to maintain a clean surface. The presence of a positive catalyzer enables a reaction to proceed more rapidly at a lower temperature than corresponds to the natural rate of the reaction. This increases the amount of substances converted in a given time, decreases the demands as to temperature resistance of materials of construction of the apparatus, and frequently makes possible a state of equilibrium (below) more favorable to the yield of desired material.

III. *The End-point of Chemical Reactions.* If a chemically reactive system is isolated from the rest of the universe at a constant temperature and pressure, a definite end-point is often attained short of the complete transmutation of reactants into resultants. In order to be certain that this end-point (short of complete transmutation) is what is known as the **equilibrium** point, the equilibrium must be approached from both directions, e.g., $A + B \rightarrow C + D$ and $C + D \rightarrow A + B$. If the value of the equilibrium constant (below) is the same when approached from both directions, then the reaction is one of true chemical equilibrium. Such equilibrium reactions are also referred to as balanced or reversible reactions. In such reactions the extent of the chemical change is proportional to the concentrations of all the reactants—reactants and re-

sultants being interchangeable, depending upon the direction of the reaction. (Generalization of Guldberg and Waage, 1864, called Law of Mass Action, or more correctly Law of Concentration Effect. Reaction studied by Guldberg and Waage (1867): Barium sulfate plus potassium carbonate plus barium carbonate plus potassium sulfate.)

A classical case, frequently cited, is that investigated by Berthelot in 1863. When 1 mol (60 grams) of acetic acid (CH_3COOH) and 1 mol (46 grams) of ethyl alcohol (C_2H_5OH), both of which substances are soluble in water, are mixed, a reaction takes place which results in the formation of water and ethyl acetate ester, which is likewise in the ratio of 1 mol (18 grams) of water, and 1 mol (88 grams) of ethyl acetate ($CH_3COOC_2H_5$). On the other hand, when 1 mol of water and 1 mol of ethyl acetate ester are mixed, a reaction takes place which results in the formation of acetic acid and ethyl alcohol in the ratio of 1 mol of acetic acid and 1 mol of ethyl alcohol. Three important observations have resulted from the detailed study of this reaction, namely, (1) the reaction between acetic acid and ethyl alcohol as reactants proceeds at such a rate that the fraction 0.00575 of the amount present at any instant reacts, at 6° to 9° C., in 1 day to form equivalent amounts of water and ethyl acetate ester, (2) the reaction between water and ethyl acetate ester as reactants proceeds at such a rate that the fraction 0.00144 of the amount present at any instant reacts, at 6° to 9° C., in 1 day to form equivalent amounts of acetic acid and ethyl alcohol, and (3) the end-point of each reaction is the same, that is, the reaction is one of true chemical equilibrium, and the resulting equilibrium mixture contains, in each case, 0.33 mol acetic acid plus 0.33 mol ethyl alcohol plus 0.67 mol water plus 0.67 mol ethyl acetate ester. This system attains practical equilibrium, at 6° to 9° C. in about 1 year, at 100° C. in about 8 days, and at 200° C. in about 24 hours.

The equilibrium constant is calculated numerically as follows:

Equation:	CH_3COOH +	$C_2H_5OH \rightleftarrows$	HOH +	$CH_3COOC_2H_5$
Reaction weights.	60	46	18	88
Molar ratio at equilibrium:	0.33	0.33	0.67	0.67
Weights at equilibrium:	0.33×60	0.33×46	0.67×18	0.67×88

$$\left.\begin{array}{l}\text{Equilibrium}\\ \text{constant at } 9^\circ\text{ C}\end{array}\right\} = \frac{\text{conc. } HOH \times \text{conc. } CH_3COOC_2H_5}{\text{conc. } CH_3COOH \times \text{conc. } C_2H_5OH}$$

$$= \frac{0.67 \times 0.67}{0.33 \times 0.33} = 4$$

Knowing the equilibrium constant at any stated temperature enables one to calculate the equilibrium end-point at that temperature for any ratio of reactants. Thus, when 1 mol (60) grams of acetic acid and 10 mols (460) grams of ethyl alcohol at 9° C. are taken:

$$\text{Equilibrium constant at } 9^\circ\text{ C.} = 4 = \frac{X \times X}{(1 - X) \times (10 - X)}$$

where X is the number of mols of water and also the number of mols of ethyl acetate ester formed (1 mol of each is formed by reaction of 1 mol acetic acid plus 1 mol ethyl alcohol). Solution of this equation shows $X = 0.97$. Therefore, by taking the above ratio of acetic acid (1 mol) to ethyl alcohol (10 mols) 0.97 (or 97%) of the acetic acid, the excess reactant being ethyl alcohol (9 mols), is converted at equilibrium into water plus ethyl acetate ester. In practice, the reaction is conducted by the use of a catalyzer, e.g., sulfuric acid concentrated, zinc chloride.

In cases where one of two resultants can be separated from the reactants and the other resultant, by precipitation as a solid, by condensation as a liquid, or by volatilization as a gas or vapor, the yield of the desired substance from a given amount of reactants can sometimes be materially increased. In the case of heterogeneous systems (those that are not homogeneous) whenever a solid participant is present, the *concentration* of said solid is considered constant. The precipitation and solution of solids are in this category, as well as the reactions between a gas and a solid, e.g., the system ferroferric oxide plus hydrogen gas plus iron plus water vapor.

The effect of change of temperature on a system in chemical equilibrium is that the equilibrium point is shifted (1) towards the side *away* from that which evolves heat when the temperature is *raised,* and (2) towards the side which evolves heat when the temperature is lowered. It is *as if* the amount of heat were a *material* reactant and its concentration (temperature or intensity of heat) increased, in respect to the *direction* of the shift of the equilbrium point. The amount of the shift at constant pressure can be calculated in cases where one possesses the proper data. (See **Thermochemistry.**)

The effect of change of pressure on a system in chemical equilibrium is that the equilibrium point is shifted (1) towards the side possessing the smaller aggregate volume when the pressure is increased, and (2) towards the side possessing the larger aggregate volume when the pressure is decreased. The amount of the shift at constant temperature can be calculated by means of the equilibrium constant (above) recalling that increase of pressure is equivalent to increase of concentration of gases (temperature constant). When the volume of resultants equals the volume of reactants, no effect is produced on the equilibrium point by change of pressure. (See **Equilibrium.**)

Chemical Equations. In calculating the equilibrium constant (above) the equation of the reaction was presented and the reaction weights inserted. Every chemical reaction between pure substances (individual chemicals) with the formation of pure substances is capable of being represented in the form of a chemical equation, wherein the formula of each pure substance has the significance stated in chemical composition, section II, Compounds and related topics. The only difficulty which should present itself to the uninitiated is that of always recalling that the formula of each chemical substance stands for a definite chemical unit weight (or volume, if a gas). In the vast majority of reactions encountered in practice the writing of the chemical equation of a reaction is comparatively simple when one knows (1) what substances are reactants, (2) what substances are resultants, (3) the formula of each. The sum of the weights (masses) of reactants equals the sum of the weights (masses) of the resultants. Without this information, equations cannot be written.

Grand Groups of Chemical Reactions. Certain grand groups of reactions are recognized. The classification may be carried further with extensive additions as desired.

1. **Reactions involving recombination of ions**
2. **Reactions involving water**
   (a) Consumption of water
   (b) Production of water
   (c) Water as catalyzer
3. **Reactions involving oxidation—reduction**
   (a) In solutions of electrolytes
   (b) Not in solutions of electrolytes. (R.K.S.)

CHEMICAL COMPOSITION. The following outline will make clear the subjects discussed under chemical composition of substances. For the chemical changes undergone by such substances see **Chemical Changes.**

I. Elements, symbols, atoms, allotropes (allotropy), isotopes (isotopy), isobares, atomic constants.
II. Compounds, formulas, molecules, allotropes (allotropy), molecular constants, isomers (isomerism, stereoisomerism).

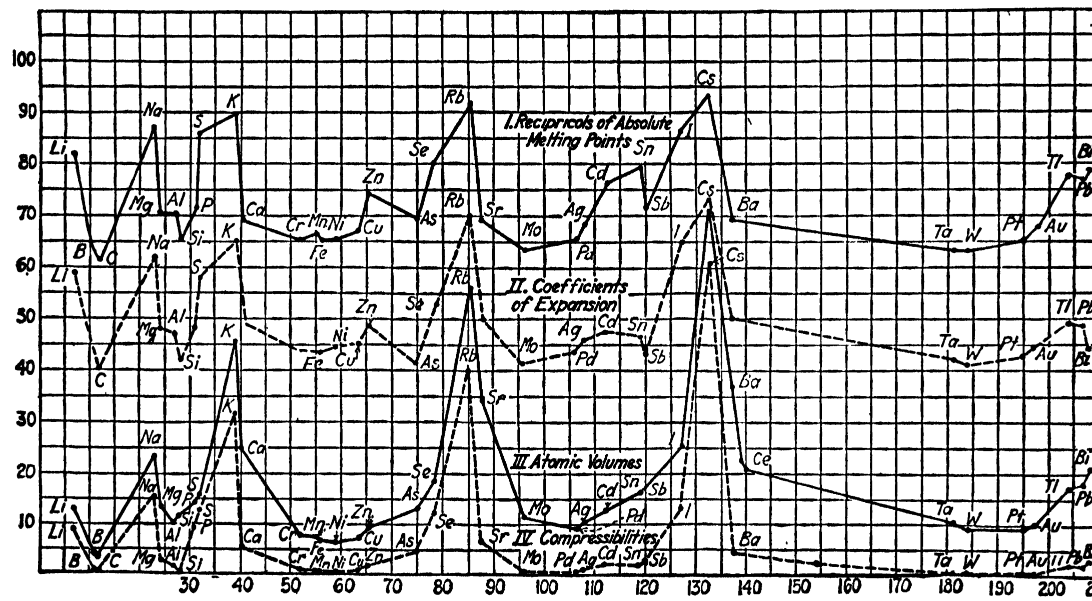
III. Radicals.
IV. Equivalents, valency, graphical formulas.

I. Elements and Related Topics

At the present time there are recognized by the Committee on Atomic Weights of the International Union of Chemistry 86 chemical elements. For list see **Chemistry.** The most recent additions to the list are **hafnium** in 1927, **rhenium** in 1929, and **protactinium** in 1937. Some elements have been known since prehistoric times, e.g., the common metals; some have been proved to be elements that were previously considered not elements, e.g., **chlorine** (Davy, 1810); some have been discovered by new methods of investigation, e.g., by the spectroscope (Bunsen and Kirchhoff); **cesium** (1860), **rubidium** (1861), **helium** in the spectrum of the sun by Janssen and Lockyer in 1868 and in certain minerals of the earth by Ramsay and by Cleve independently in 1895, by the ago with some confidence. The Moseley atomic number is probably the best peg on which to hang the concept of atom as used practically. This constant, along with the Mendeléeff placement of the elements, makes it clear that the elements form a system. Other data confirm this. Symbol weights—commonly known as atomic weights—of the elements are relative numbers for the mass of each element based on the standard of reference, oxygen equal to 16.0000. The alphabetical table of elements on page 288 gives the name, symbol, atomic number and atomic weight.

Other constants of certain atoms are given (pp. 288, ff.): namely, atomic volume, atomic heat, atomic radius, atomic compressibility. Constants in frequent use are hardness, crystal form, melting point, boiling point, vapor pressure; also important, spectrum, both visible and x-ray.

Atomic volume is the volume in milliliters occupied by 1 atomic weight in grams of the solid element, there-



Graph showing periodicity of the physical properties of the elements.

x-ray spectra (Moseley, 1914), e.g., hafnium by Coster and Hevesy in 1923, and rhenium by Walter Noddack and Ida Tacke in 1925.

The introduction of a systematic relationship among the chemical elements is due to Mendeléeff in 1869. His pronouncement was that the properties of elements, as well as the forms and properties of their compounds, are in periodic dependence on the atomic weight of the elements. A full account is given in the Faraday Lecture of the Chemical Society (London) on "The Periodic Law of the Chemical Elements" delivered by Mendeléeff on June 4, 1889. This periodic arrangement is the one in common use at the present time. Extension and experimental verification of the periodic arrangement are due to the work on x-ray spectra of the chemical elements by Moseley in 1914, who was able to assign a serial number, called the atomic number, to each of the elements from hydrogen 1 to uranium 92. As was stated above, the identity of 86 of these has been officially recognized, and some of the remaining are known to exist in the radioactive series of elements, namely, uranium X_2 of atomic number 91, mesothorium 2 of atomic number 89, and several of atomic numbers 81, 82, 83, 84, 86, 88, 90, 92. (See **Radioactive Changes.**)

It is not attempted here to define a chemical element in a simple manner, as could have been done some years fore, atomic weight (grams) divided by density (specific gravity) of the solid element equals atomic volume (milliliters).

Atomic heat is the amount of heat required to raise the temperature 1° C. of 1 **atomic weight** in grams of the solid element at a given temperature, therefore, atomic weight (grams) multiplied by specific heat of the solid element equals atomic heat (calories). The atomic heat values given are not exactly comparable—the temperature is as stated in each case. Omitting **beryllium, boron, carbon, sodium, silicon, potassium, titanium,** the remaining 23 elements show a value within 1% of 6.1 (Dulong and Petit's generalization of constancy of atomic heat (1819)). (For Molecular heat, see following section II, Compounds and related topics.) Atomic radius as determined by Neuburger (1936) using x-ray studies. Atomic compressibility is the fractional change in volume of the solid element corresponding to a given change in pressure at a constant temperature.

Due to the investigations initiated by J. J. Thomson (1913) using neon gas in a low vacuum discharge tube and examining the effects of **anode** rays, the discovery was made that neon consists of two (later three) masses of atoms about 90% of the 20 and about 10% of the 22 mass (later, 20 (90%), 21 (0.27%), 22 (9.73%)). The work in this field has progressed since 1919 in the

The following arrangement, using the accepted symbols (see Atomic Weights, page 288), summarizes the above:

PERIODIC CLASSIFICATION OF THE CHEMICAL ELEMENTS ACCORDING TO MENDELÉEFF AND MOSELEY

Number	Group O	I	II	III	Sub-Group iv	v	vi	vii	viii			i	ii	iii	Group IV	V	VI	VII
1		H																
2–9	He	Li	Be	B											C	N	O	F
10–17	Ne	Na	Mg	Al											Si	P	S	Cl
18–35	A	K	Ca	Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn	Ga	Ge	As	Se	Br
36–53	Kr	Rb	Sr	Y	Zr	Cb	Mo	(43)	Ru	Rh	Pd	Ag	Cd	In	Sn	Sb	Te	I
54–85	Xe	Cs	Ba	La–Lu 57–71 (Below)	Hf	Ta	W	Re	Os	Ir	Pt	Au	Hg	Tl	Pb	Bi	(84)	(85)
86–96	Rn	(87)	Ra	(89)	Th	Pa	U	(93)	(94)	(95)	(96)							

57–71 of Group III:	La	Ce	Pr	Nd	(61)	Sa	Eu	Gd	Tb	Dy	Ho	Er	Tm	Yb	Lu

NOTES:

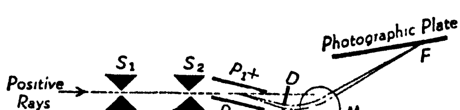
Element 43, masurium, announced by Walter Noddack and Ida Tacke 1925.
Element 61, illinium, announced by Harris, Yntema and Hopkins, 1926.
Element 84, radioactive element known.
Element 85, alabamine, announced by Allison and Murphy, 1929.
Element 87, virginium, announced by Allison and Murphy, 1929, and by Papish and Wainer, 1931.
Element 89, radioactive element, mesothorium 2.
Element 93, neptunium, a product of atomic bomb research, formed by radioactive change spontaneously from uranium 239 by emission from the latter of a beta particle (high energy electron).
Element 94, plutonium, a product of atomic bomb research, formed by radioactive change spontaneously from neptunium 239 by emission from the latter of a beta particle. (See **Atomic Bomb.**)
Element 95, americium, announced by Glenn T. Seaborg and co-workers in 1946. Possesses six 5F electrons corresponding to europium which has six 4F electrons.
Element 96, curium, announced by Glenn T. Seaborg and co-workers in 1946. Possesses seven 5F electrons corresponding to gadolinium which has seven 4F electrons.

Groups by name:

Group O, rare or noble gases
Group I, Li–Cs, alkali metals
Group II, alkaline earth metals
Group III, Sc–Lu, rare earth metals
Group viii, Ru, Rh, Pd, Os, Ir, Pt, rare or noble metals
Group VII, halogens

---

hands of Aston and co-workers to such a degree of accuracy that the atomic weight of **hydrogen** by this method of the mass-spectograph is, since 1929, the accepted value. Substances which are recognized from their Mendeléeff-Moseley properties as chemical elements and which are *not* made up of atoms which are all of



Aston's mass-spectrograph.

the same weight, as neon above, are said to consist of isotopes. Isotopes of a given element possess the same chemical properties but different masses. That is, neon 20, 21, 22 are chemically indistinguishable isotopes. Physical confirmation of the existence of isotopes has been obtained by separation of neon into two fractions of different densities by effusion (Aston, 1920), (Hertz, 1932). The partial separation of isotopes of a given element has been successfully accomplished also in the case of **mercury** by Brönsted and Hevesy (1920) using fractional **distillation**; of **chlorine** by Brönsted and Hevesy (1920) and by Harkins and Hayes (1921) by fractional diffusion through pipeclay; and of **hydrogen** by Urey (1932). Washburn and Urey (1932) found that the residual water of electrolytic cells, which had been operated for years without drawing off the caustic solution, contained a marked increase in abundance of mass 2 hydrogen relative to mass 1 (see **Water**).

Isotopes of radioactive elements are discussed under **Radioactive Changes.**

A table of isotopes of the elements, arranged in two columns, the one containing the odd-numbered, the other the even-numbered elements, is presented. (Page 290) Odd-numbered elements have at the most two isotopes (Aston). Of 38 odd-numbered elements, 19 are single; of 41 even-numbered elements, 4 only are single. Isobares are elements of the same mass but different chemical properties, e.g., titanium 50 and chromium 50.

The method of positive or anode-ray analysis by the mass-spectograph involves the use of a gaseous or volatilizable element or compound of the element. The blank spaces in the preceding table are accounted for by the fact that no satisfactory volatile compound has yet been found for the elements in question.

Allotropic elements are those which present different physical forms of the same elementary chemical composition. The energy content and the volume of the different forms are not the same, and frequently a given temperature determines the transformation of one form to the other. In the case of **oxygen** and ozone the composition O_2 and O_3, respectively, makes it easy to understand the differences in behavior, but in other cases, different internal arrangements of the substances must be assumed.

INTERNATIONAL TABLE OF ATOMIC WEIGHTS

II. Compounds and Related Topics

When two or more chemical elements are present in a substance possessing properties, e.g., melting point, boiling point, density, percentage composition by elements, that are constant and individual for the substance, the given substance is regarded as a compound.

Water and carbon dioxide are two of the most important substances of everyday life that are definite compounds. See **Water**, and **Carbon, oxides,** for full description of these compounds, also **Hydrogen Peroxide** for another compound which contains the same elements, namely, hydrogen and oxygen, as water, and carbon, oxides, for other compounds which contain the same elements, namely, carbon and oxygen, as carbon dioxide—these are carbon monoxide and carbon suboxide.

The formulae of gaseous compounds are obtained from a study of the composition by elements and the density, by a method introduced by the Italian chemist, Cannizzaro in 1858. Later, in 1872, in the course of his Faraday Lecture before the Chemical Society (London) on the subject "Some Points in the Teaching of Chemistry" Cannizzaro stated that "Symbols and formulas, in my opinion, constitute the introduction, preparation, and base of the study of the transformations of matter, which is the true object of our science." The simplest way to understand the method is to arrange in tabular form, (1) the individual gases, (2) the weight in grams

DISPLAY OF DATA TO ILLUSTRATE THE CANNIZZARO METHOD OF ARRIVING AT THE SYMBOL AND SYMBOL WEIGHT OF CHEMICAL ELEMENTS, AND THE FORMULA AND FORMULA WEIGHT OF CHEMICAL COMPOUNDS

Gas	Grams per 1 Standard Liter	Percentage Composition by Chemical Elements	Grams per 1 Standard Liter by Chemical Elements: Hydrogen	Oxygen	Carbon	Nitrogen	Sulfur	Chlorine
1. Hydrogen chloride.	1 639	Hydrogen 2 76% / Chlorine 97 24	0 045				.....	1 594

11. Chlorine	3.214	Chlorine 100.00	.. .	...	.	....	. ..	3 214
12. Sulfur dioxide...	2 927	Oxygen 49 95 / Sulfur 50 05	....	1 462	. ...	....	1 465	
13. Hydrogen sulfide...	1.539	Hydrogen 5 91 / Sulfur 94.09	0.091	... ..	......	.	1 448	
14. Nitrous oxide......	1 978	Oxygen 36.35 / Nitrogen 63.65	....	0.719	....	1.259		
15. Nitric oxide.......	1.340	Oxygen 53 32 / Nitrogen 46.68	....	0 715	......	0.625		
Minimum weight (approximate)..........	....	.. ..	0 045	0 715	0 538	0 626	1 45	1 60

of 1 liter (at 0° C., 760 mm. of mercury pressure) of each gas, (3) the weight in grams of *each element* present in the above volume (1 standard liter) found by exact analysis (percentage composition by chemical elements using the methods of analytical chemistry), as on the preceding page.

Careful examination of the figures in the last six columns reveals the experimental fact that (1) in each separate vertical column the figures represent a minimum weight or a small multiple (approximately) of this weight, (2) the smallest of the six minimum weights is that for hydrogen, namely, 0.045 gram in 1 standard liter of hydrogen chloride gas.

The next step involves changing 0.045 gram of hydrogen to exactly 1.000 gram and finding arithmetically the volume of hydrogen chloride containing this weight (1.000 gram hydrogen). The volume is found to be 22 2 standard liters.

Therefore, 1.000 gram minimum weight of hydrogen is contained in 22.2 standard liters of hydrogen chloride.

Using this standard volume of 22.2 liters, the next step is to ascertain the minimum weight of the other elements in this volume.

Chemical Element	Hydrogen	Oxygen	Carbon	Nitrogen	Sulfur	Chlorine
Approximate minimum weight in grams of each of the six chemical elements in the standard volume, 22.2 liters..........	1 gram	16 grams	12 grams	14 grams	32 grams	35.5 grams

Then, the abbreviation is introduced of representing:

SYMBOL WEIGHTS OF EACH ELEMENT BY THE SYMBOLS

1 gram of hydrogen	by the symbol	H
16 grams of oxygen	" " "	O
12 grams of carbon	" " "	C
14 grams of nitrogen	" " "	N
32 grams of sulfur	" " "	S
35.5 grams of chlorine	" " "	Cl

By setting up again the second half of the table for the 15 gases, this time for 22.2 standard liters instead of 1 standard liter, the results obtained may be observed in the table on the following page.

Thus, it is seen, the chemical formulae and formula weights (last column) of 15 gaseous chemical compounds have been arrived at, using the Cannizzaro method, by purely experimental and rational means, involving no theoretical considerations. Extension of the method serves to ascertain the chemical formula of all gases and vaporizable substances. For compounds which are neither gases nor vaporizable, other methods are available. Of these the most used are those of Raoult depending upon the depression of the freezing point or the elevation of the boiling point of a compound dissolved in a given **solvent.** (See **Solutions.**)

It remains to be noted that, when there is no method available for ascertaining the formula weight of a compound, the *simplest* formula, based on chemical analysis and the use of symbol weights of the contained elements, is used, e.g., ferric oxide, Fe_2O_3, ferroferric oxide, Fe_3O_4, ferrous oxide, FeO, cupric oxide (black copper oxide), CuO, cuprous oxide (red copper oxide), Cu_2O. The customary formula of water is H_2O, which is correct at temperatures above 100° C.—actually, liquid water is mainly dihydrol $(H_2O)_2$.

It should be understood from the above discussion that a chemical formula is no chance throwing together of chemical symbols, but represents the results of careful analysis, and the scrutiny and deduction of the most skillful workers in the field. On this score alone, chemical formulae demand the greatest respect in understanding and use.

Symbol weights and atomic weights are used synonymously. Formula weights and molecular weights are used synonymously. Unless otherwise stated, symbol weights and formula weights are expressed in grams, and the numbers used are those taken from the accepted list of atomic weights. See preceding section I, Elements and related topics.

One formula volume of a gas is 22.2 liters. It is necessary to state that actual gases under ordinary conditions show some variation from this value, so that for accurate work the records should be consulted in each case. The volume, 22.4 liters (1% larger than used in the above deductions) is commonly used.

Summarizing, the formula "HCl" states that "36.5 grams of hydrogen chloride gas occupies a standard volume of 22.2 liters and is composed of 1 gram of hydrogen element chemically united with 35.5 grams of chlorine element." The reason for the formulae of the simple gases, oxygen, O_2, hydrogen, H_2, nitrogen, N_2, chlorine, Cl_2, is apparent from the general method of deduction. The formula O_2 represents 22.2 liters or 32 grams of oxygen *gas,* whereas O represents 16 grams of oxygen *element* in any substance.

Other constants of **molecules** are similar in kind to those referred to under atoms (see preceding section I, Elements and related topics), namely, hardness, crystal form, melting point, boiling point, vapor pressure, molecular volume, molecular heat (see below), molecular dimensions of gases, allotropy and transformation temperatures. Molecular properties of great significance in organic chemistry are those of **isomerism** and stereoisomerism, and molecular dissociation, and **association.** A molecule of a chemical compound may be defined as the smallest unit which retains the characteristic properties of the compound.

It has become customary in chemical literature to use the formula of a substance as an accepted abbreviation for the name of the substance, especially in cases of frequent repetition.

The molecular heat of a solid compound is equal to the sum of the atomic heats (see preceding section I, Elements and related topics) of the elements of the compound. This generalization is the result of investigations by Kopp (1864). Since several elements that are commonly found in solid compounds are not themselves solids or are not, at ordinary temperature, in agreement with the atomic heat constant, 6.1, calculated values from experimental observations of the molecular heat of solid compounds have been assigned to them. Nernst recommended that the following values be used·

Oxygen..........	4.0	Phosphorus.......	5.4
Hydrogen.........	2.3	Sulfur..	5.4
Carbon............	1.8	Boron	3.7
Silicon...........	3.8	Fluorine.	5.0

The term molar fraction is used to express the ratio of the number of gram mols of one compound present in a system to the total number of gram mols of all the compounds present in that system Thus, formaldehyde solution is approximately 40% formaldehyde (HCHO, formula weight 30) and 60% water (H_2O, formula weight 18)

$$\frac{\text{number of mols HCHO}}{\text{number of mols HCHO} + \text{number of mols } H_2O} = \frac{\frac{40}{30}}{\frac{40}{30}+\frac{60}{18}}$$

$$= \frac{1.33}{4.66} = 0.285, \quad \text{molar fraction of formaldehyde.}$$

This value multiplied by 100 gives the molecular percentage, namely, 28.5 molecular per cent formaldehyde

DERIVATION OF FORMULAE AND FORMULA WEIGHTS OF GASES, HAVING GIVEN THE PERCENTAGE COMPOSITION BY CHEMICAL ELEMENTS OF EACH GAS AND THE SYMBOLS AND SYMBOL WEIGHTS OF THE ELEMENTS CONTAINED

solution (40 weight per cent of formaldehyde solution. For "volume per cent" see **Ethyl Alcohol**).

III. Radicals

In many chemical compounds there are groups of two or more elements that frequently have the properties of or enter into chemical reaction as a unit. Of those which are of outstanding importance the following are cited·

(1) **Ammonium** (NH_4—) behaves as a unit in ammonium compounds and in some of these compounds is very similar to **potassium** (K—) in potassium compounds.

(2) Hydroxyl (—OH) which behaves as a unit in bases (e.g., **sodium** hydroxide, NaOH), **alcohols** (e.g., methyl alcohol, CH_3OH), and **phenols** (e.g., phenol, C_6H_5OH).

(3) Anion-groups of acids, their salts and their esters: **Sulfate** ($>SO_4$), **sulfite** ($>SO_3$), **nitrate** (—NO_3), **nitrite** (—NO_2), **phosphate** ($\geqslant PO_4$), **perchlorate** (—ClO_4), **chlorate** (—ClO_3), **chlorite** (—ClO_2), **hypochlorite** (—OCl), **carbonate** ($>CO_3$), **formate** (—CHO_2), **acetate** (—$C_2H_3O_2$), **palmitate** (—$C_{16}H_{31}O_2$), **stearate** (—$C_{18}H_{35}O_2$), **oleate** (—$C_{18}H_{33}O_2$), **oxalate** ($>C_2O_4$), lactate (—$C_3H_5O_3$), malate ($>C_4H_4O_5$), **tartrate** ($>C_4H_4O_6$), citrate ($\geqslant C_6H_5O_7$), benzoate (—$C_7H_5O_2$), cinnamate (—$C_9H_7O_2$), phthalate ($>C_8H_4O_4$), salicylate (—$C_7H_5O_3$). See **Acids, Carboxylic**, for others.

(4) Alkyl- and aryl-groups of alcohols, phenols, their esters and their alcoholates and phenolates: (a) Alkyl (non-benzenoid)-methyl (CH_3—), ethyl (C_2H_5—), propyl (C_3H_7—), butyl (C_4H_9—) and similar radicals of alcohols (see **Alcohols** for others); (b) Aryl (benzenoid)-phenyl (C_6H_5—), tolyl (C_7H_7—), xylyl (C_8H_9—), naphthyl ($C_{10}H_7$—) and similar radicals of phenols. (See **Phenols** for others.)

(5) Acyl-groups of organic acids: acetyl (CH_3CO—), benzoyl (C_6H_5CO—). (See **Acids, Carboxylic,** for others.)

(6) Miscellaneous radicals, for example, cacodyl ($(CH_3)_2As$—), celebrated on account of the investigations by Bunsen (1838).

All of the above radicals are associated with a corresponding radical or element in a compound. While a radical frequently and rather generally enters into chemical reaction as a unit, it is not implied that this is always so, the stability in each case is characteristic of each radical and each reaction in which it is involved. Thus, **ammonium** hydroxide (NH_4OH) yields **ammonia** gas (NH_3) and water (H_2O) at room temperature; ammonium nitrate (NH_4NO_3) is decomposed, upon heating, with the accompanying disruption of both the ammonium and nitrate radicals to yield **nitrous oxide** (N_2O) gas and water (H_2O).

Radicals enter widely into reactions involving electrolytic dissociation of salts, acids, bases in water solution. (See **Reactions Involving Recombinations of Ions.**)

Except in rare cases, free radicals are not encountered. Gomberg (1900), by treating triphenylmethyl chloride in an atmosphere of **carbon dioxide,** with zinc, silver, or mercury, obtained the free radical, triphenylmethyl. On dissolving the colorless solid in organic solvents a yellow solution is obtained, and the reactivity (due to unsaturation) of the yellow solution is marked towards **oxygen,** dissolved **iodine, ether.** Triphenylmethyl is present in solution in two forms, (1) monomolecular ($(C_6H_5)_3C$) yellow, in equilibrium with (2) dimolecular ($((C_6H_5)_3C)_2$ colorless. But tribiphenylmethyl ($(C_6H_5$—$C_6H_4)_3C$) occurs only in the monomolecular form, purple. The action of alkali metals on **ketones** in some cases produces metallic ketyl (Schlenk, 1913) thus: $\begin{matrix}R'\\R''\end{matrix}\!\!>C$—ONa, which is a free radical, or contains trivalent carbon as does monomolecular triphenylmethyl.

IV. Equivalents, Valency, Graphical Formulas

In the preceding section on radicals, each radical is written with one or more accompanying lines, characteristic for each, (a) on the right-hand side for ammonium, alkyl, aryl, acyl, and (b) on the left-hand side for hydroxyl, anion groups. The metals in their salt compounds would be similarly written (a) on the right-hand side, thus, sodium (Na—), calcium (Ca$<$), aluminum (Al$\leqslant$), (also hydrogen (H—) of water, acids, etc.), and the non-metals in their salt compounds would be similarly written (b) on the left-hand side, thus, chloride (—Cl), bromide (—Br), iodide (—I), sulfide ($>$S), nitride ($\geqslant$N), (also oxygen ($>$O) of water, oxides, etc.). Compounds that are known to consist of the union of these (a) and (b) radicals and elements are found to be united "bond for bond," thus water,

(H_2O) (H—OH or $\begin{smallmatrix}H\\H\end{smallmatrix}\!>\!O$); hydrochloric acid, (HCl) (H—Cl); sulfuric acid, (H_2SO_4) ($\begin{smallmatrix}H\\H\end{smallmatrix}\!>\!SO_4$ or $\begin{smallmatrix}O\\O\end{smallmatrix}\!\gg\!S\!<\!\begin{smallmatrix}OH\\OH\end{smallmatrix}$); nitric acid, HNO_3 (H—NO_3 or $\begin{smallmatrix}O\\O\end{smallmatrix}\!\gg\!N$—OH); phosphoric acid, H_3PO_4 ($\begin{smallmatrix}H\\H\\H\end{smallmatrix}\!>\!PO_4$ or O=P$\!<\!\begin{smallmatrix}OH\\OH\\OH\end{smallmatrix}$); acetic acid, $HC_2H_3O_2$ (H—$C_2H_3O_2$ or CH_3CO—OH or H—OOC·CH_3 or $\begin{smallmatrix}H\\H\\H\end{smallmatrix}\!>\!C$—C$\!\ll\!\begin{smallmatrix}O\\OH\end{smallmatrix}$); oxalic acid, $H_2C_2O_4$ ($\begin{smallmatrix}H\\H\end{smallmatrix}\!>\!C_2O_4$ or $\begin{smallmatrix}O=C-OH\\ |\\ O=C-OH\end{smallmatrix}$); acetyl chloride, ($CH_3CO$—Cl or $\begin{smallmatrix}H\\H\\H\end{smallmatrix}\!>\!C$—C$\!\ll\!\begin{smallmatrix}O\\Cl\end{smallmatrix}$); silver chloride, Ag—Cl, cupric chloride, $CuCl_2$, green soluble solid (Cu$\!<\!\begin{smallmatrix}Cl\\Cl\end{smallmatrix}$); cuprous chloride, CuCl, white insoluble solid, or Cu_2Cl_2 (vapor) (Cu—Cl or $\begin{smallmatrix}Cu-Cl\\ |\\ Cu-Cl\end{smallmatrix}$); cupric oxide, CuO, black insoluble solid (Cu=O); cuprous oxide, Cu_2O, red insoluble solid ($\begin{smallmatrix}Cu\\Cu\end{smallmatrix}\!>\!O$); magnesium oxide, MgO, white insoluble solid (Mg=O); magnesium nitride, Mg_3N_2, yellow solid yielding ammonia with water ($\begin{smallmatrix}Mg\\Mg\\Mg\end{smallmatrix}\!\gg\!\begin{smallmatrix}N\\N\end{smallmatrix}$); ammonium nitrate, NH_4NO_3 (NH_4—NO_3 or $\begin{smallmatrix}H\\H\\H\\H\end{smallmatrix}\!>\!N$—N$\!\ll\!\begin{smallmatrix}O\\O\\O\end{smallmatrix}$); ethyl alcohol, C_2H_5OH (C_2H_5—OH or $\begin{smallmatrix}H\\H\\H\end{smallmatrix}\!>\!C$—$\begin{smallmatrix}H\\C\\H\end{smallmatrix}$—OH). Also, oxygen gas, O_2 (O=O); chlorine gas, Cl_2 (Cl—Cl); nitrogen gas, N_2 (N≡N); hydrogen gas, H_2 (H—H); cyanogen gas, $(CN)_2$ ($\begin{smallmatrix}CN\\ |\\ CN\end{smallmatrix}$ or $\begin{smallmatrix}C\equiv N\\ |\\ C\equiv N\end{smallmatrix}$).

VALENCY OF CERTAIN CHEMICAL ELEMENTS

Positive							0	Negative			
7	6	5	4	3	2	1		1	2	3	4
						H^{1+} In water, acids, methane			O^{2-} In water, oxides, bases, alcohols, aldehydes		
		N^{5+} In nitrogen pentoxide, nitrates, nitro-compounds		N^{3+} In nitrogen trioxide, nitrites, nitroso-compounds	N^{2+} In nitric oxide					N^{3-} In ammonia, ammonium compounds ($N^{1+,4-}$)	
		P^{5+} In phosphorus pentoxide, phosphates		P^{3+} In phosphorus trioxide, phosphites		P^{1+} In hypophosphites				P^{3-} In phosphine, phosphonium compounds ($P^{1+,4-}$)	
	S^{6+} In sulfur trioxide, sulfates		S^{4+} In sulfur dioxide, sulfites						S^{2-} In sulfides		
Cl^{7+} In perchlorates		Cl^{5+} In chlorates		Cl^{3+} In chlorites		Cl^{1+} In hypochlorites		Cl^{1-} In chlorides			
			C^{4+} In carbon dioxide, carbonates		$C^{3+,1-}$ In carbon monoxide, formic acid		$C^{2+,2-}$ In formaldehyde		$C^{1+,3-}$ In methyl alcohol		C^{4-} In methane
			Si^{4+} In silicates	Al^{3+} In aluminum compounds	Ca^{2+} In calcium compounds	Na^{1+} In sodium compounds	Free elements Na°, Ca°, Al°, Si°, Cu°, Fe°, Mn°, Cr°, C°, S°, P°				
					Cu^{2+} In cupric compounds	Cu^{1+} In cuprous compounds					
				Fe^{3+} In ferric compounds	Fe^{2+} In ferrous compounds						
Mn^{7+} In permanganates	Mn^{6+} In manganates		Mn^{4+} In manganese dioxide	Mn^{3+} In manganic compounds	Mn^{2+} In manganous compounds						
	Cr^{6+} In chromates			Cr^{3+} In chromic compounds	Cr^{2+} In chromous compounds						

(See **Reactions Involving Oxidation, Reduction** (B) (2) for more complete list.)

The last formula in each of the above examples is known as the graphical formula of the compound. Graphical formulae are of great significance in the field of organic chemistry. They are frequently partially abbreviated, thus, ethyl alcohol, above, is often written $CH_3—CH_2OH$.

The number of lines shown accompanying each radical or element is a measure of its valency. Univalent radicals are equivalent. Higher valent radicals are equivalent "bond for bond." The univalent radicals, ammonium ($NH_4—$) and nitrate ($—NO_3$) are equivalent in *combining power* (ammonium nitrate NH_4NO_3). The divalent radical sulfate ($>SO_4$) and the univalent radical nitrate ($—NO_3$) are equivalent 1 to 2 in *replacing power* (copper sulfate $CuSO_4$, copper nitrate $Cu(NO_3)_2$). These values have been experimentally determined in each case, based on certain elementary assumptions, principally two, namely, (1) oxygen in most chemical compounds has a valency of minus two ($>O^{2-}$), (2) hydrogen in most chemical compounds has a valency of plus one ($H—^{1+}$). The cases where oxygen is zero ($—^{1+}O^{1-}—$) and hydrogen minus one ($—H^{-1}$) are rare (hydrogen peroxide

$$\left(\begin{array}{l} H^{+1}—^{-1}O^{+1} \\ \qquad\quad | \\ H^{+1}—^{-1}O^{-1} \end{array}\right) \text{ and calcium hydride } \left(Ca^{+2}\begin{array}{l} \diagup H^{-1} \\ \diagdown H^{-1} \end{array}\right)$$

respectively.)

Grand Groups of Chemical Substances—Elements and Compounds. Certain grand groups of substances are recognized. The classification may be carried further with subdivisions extended as desired.

1. Acids, bases, salts (see **Acids, Bases, Salts; Individual Acids; Acids, Carboxylic**).
2. Metals, non-metals, alloys (see Individual elements. **Alloys**).
3. Oxides, chlorides, sulfides—most important grand group of 2-element compounds (see **Oxygen,** oxides; **Chlorine,** chlorides; **Sulfur,** sulfides; **Thermochemistry**).
4. Organic compounds (see **Chemistry, B.** Organic Chemistry). (R.K.S.)

CHEMICAL COORDINATION. The coordination of complex bodies by the reaction of various parts to substances whose occurrence within the body is conditioned by its own processes. A simple example is the regulation of the rate of respiration by the concentration of **carbon dioxide** in the blood. The more striking cases of chemical coordination concern special secretions produced by glands within the body and called **hormones.** (A.W.L.)

CHEMICAL DYE DESTRUCTION. A process of image formation used in processes of color photography. Such a process is based upon the chemical destruction of a dye present in the photographic emulsion, the quantity of dye destroyed being dependent quantitatively on the presence or absence of a silver image.

If a photographic emulsion is dyed with a suitable dye and, after exposure and processing to a silver image, is treated with a solution of hydrogen peroxide, the dye will be selectively destroyed. The finely divided particles of the silver image act as a catalyst and enable the peroxide to attack the dye. The dye image remaining will be the inverse of the silver image—dye-positive image obtained by treatment of a negative silver image. With suitable dyes and processing reagents, chemical dye destruction may be controlled by either silver or silver halides. Recent advances make it unnecessary for the colored dye to be put into the emulsion during manufacture, since colorless dye formers may be incorporated in the emulsions that may be converted into colorants shortly before the chemical step of dye destruction takes place.

Chemical dye destruction has been chiefly employed in photography as a method of color formation in integral tripacks (see **Bipacks and Tripacks**). The dyes used are generally quite stable and of excellent hue and saturation. (H.C.C.)

CHEMICAL ELEMENTS. Chemical Composition.

CHEMICAL ENGINEERING is that branch of engineering concerned with the development and application of manufacturing processes in which chemical or certain physical changes of materials are involved. These processes may usually be resolved into a coordinated series of unit physical operations and unit chemical processes. The work of the chemical engineer is concerned primarily with the design, construction, and operation of equipment and plants in which these unit operations and processes are applied. Chemistry, physics, and mathematics are the underlying sciences of chemical engineering, and economics its guide in practice. (D.E.M.)

CHEMICAL EVENTS. See **History and Evolution of Chemistry.**

CHEMICAL SOCIETIES AND PUBLICATIONS

1663 Royal Society (London) founded.
1665 Philosophical Transactions of the Royal Society first published. (Volume 200, 1903.)
1699 Memoires de l'Académie des Sciences de l'Institut de France, Paris, first published. Académie founded 1666, recognized by letters patent 1713.
1780 American Academy of Arts and Sciences founded. Memoirs 1785– Proceedings 1846–
1785 Chemical Society of the University of Edinburgh in existence. Date of founding not known. Students of Joseph Black.
1789 Annales de Chimie first published.
1792 Chemical Society of Philadelphia founded by James Woodhouse.
1818 American Journal of Science first published.
1831 British Association for the Advancement of Science founded.
1835 Comptes rendues de l'Académie des Sciences (Paris) first published. (Volume 201, 1935.)
1840 Chemical News (London) first published
1841 Chemical Society (London) founded. Chartered 1848.
1848 American Association for the Advancement of Science founded. Journal of the Chemical Society (London) first published.
1857 Société Chimique de France founded. Bulletin 1858–
1863 National Academy of Sciences (U.S.A) founded.
1867 Deutsche Chemische Gesellschaft founded.
1868 Berichte der Deutschen Chemischen Gesellschaft first published. (Volume 68, 1935.)
1869 Nature (London) first published.
1871 Oil, Paint and Drug Reporter founded.
1876 American Chemical Society founded. Analyst (London) first published.
1878 Institute of Chemistry (British) founded.
1879 Journal of the American Chemical Society first published. American Chemical Journal first published. Philosophical Magazine (London) first published.
1881 Society of Chemical Industry (British) founded.
1882 Journal of the Society of Chemical Industry first published.
1883 Science first published. (New Series 1895.)
1897 Journal of Physical Chemistry first published.
1902 Electrochemical Society (U.S.A.) founded. Transactions published. Chemical and Metallurgical Engineering founded as Electrochemical Industries.
1904 Annual Reports of the Progress of Chemistry first published.
1905 Journal of Biological Chemistry first published. Transactions Faraday Society first published.

1906 American Society of Biological Chemists organized. American Men of Science first published.
1907 Chemical Abstracts first published.
1908 American Institute of Chemical Engineers founded. Transactions published.
1909 Industrial and Engineering Chemistry first published (as Journal of Industrial and Engineering Chemistry).
1912 Eighth International Congress of Applied Chemistry, Washington and New York.
1914 Chemical Industries founded as Chemical Markets.
1915 Société de Chimie Industrielle founded. First Chemical Exposition in New York.
1916 National Research Council (U.S.A.) founded. Annual Reports of the Progress of Applied Chemistry first published. Chemical Engineering Catalog founded.
1918 Chimie et Industrie first published.
1919 Proceedings of Chemical Engineering Group of Society of Chemical Industry first published.
1921 American Chemical Society Monographs established.
1923 Chemistry and Industry (London) first published. Institution of Chemical Engineers (London) founded. Transactions published. American Institute of Chemists founded. Chemical and Engineering News founded as News Edition of Industrial and Engineering Chemistry.
1924 Chemical Reviews first published. Journal of Chemical Education first published.
1928 Food Industries founded
1929 World Power Congress, Tokio. Metals and Alloys founded. Analytical Edition of Industrial and Engineering Chemistry founded.
1933 Journal of Chemical Physics first published.
1934 Ninth International Congress of Pure and Applied Chemistry, Madrid.
1935 National Farm Chemurgic Council organized.
1936 Chemical Engineering Conference of World Power Congress, London. Journal of Organic Chemistry first published. (R.K.S.)

CHEMICAL FORMULAE. The formulae of chemistry constitute a shorthand notation used to represent the composition by weight, the **molecular** properties, the characteristic chemical reactions or at times even the ordering of the **atoms** in space of the elements which go to make up the chemical compound. Chemical formulae are classified into empirical, molecular, structural or configurational, the order given being that of increasing content of information. The following steps indicate the type of chemical experiments necessary to establish the different kinds of formulae. The first step consists in the isolation of a pure chemical compound. Chemical purification can be obtained by **crystallization, distillation, adsorption, sublimation,** etc. Some of the criteria of purity which a substance must satisfy are constancy and sharpness of melting point and boiling point on repeated purification. As an example let us assume that we have succeeded in purifying a solid compound which we shall call **tartaric acid** and whose formula we wish to determine.

The second step consists in a qualitative and quantitative analysis of the compound. In the case of tartaric acid qualitative analysis tells us that the compound contains carbon, oxygen and hydrogen, while quantitative analysis shows that the proportions are 48 parts by weight of carbon, 96 of oxygen, and 6 of hydrogen. To obtain the empirical formula one divides each proportion by the atomic weight of the particular element, obtaining in this way a set of numbers which can be represented by a ratio of small integers. The simplest ratio of integers is commonly used to indicate as subscripts on the right of the chemical symbol of the element to represent the empirical formula. In the case of tartaric acid the atomic weights are 12 for **carbon,** 16 for **oxygen** and 1 for **hydrogen.** Dividing the percentages as determined by analysis by the atomic weights we get

Carbon	$48/12 = 4.00$
Oxygen	$96/16 = 6.00$
Hydrogen	$6/1 = 6.00$

The set of numbers is 4,6,6 and can be represented in this case by the ratio of integers 2:3:3. The empirical formula is therefore $C_2O_3H_3$. Empirical formula is thus only a convenient method for representing the percentage composition by weight of the different elements in the compound. The third step is the determination of the molecular weight of the compound in question. This allows us to assign to the compound a molecular formula. The molecular weight can be determined in a variety of methods such as by the determination of the weight of 22.4 liters of the vapor of the substance at 1 atmosphere pressure and 0° C., temperature. Other methods are based on the differences in the boiling point or freezing point of solutions of known concentration and those of the pure solvent. To determine the molecular formula from the knowledge of the empirical formula and the molecular weight the following procedure must be followed. Multiply the atomic weight of each element by its subscript as indicated in the empirical formula and add the result. On comparison of such a sum with the molecular weight it will be found that the molecular weight is equal to the sum times an integer. To obtain the molecular formula multiply each subscript in the empirical formula by this integer and obtain a new set of subscripts. We found the empirical formula of tartaric acid was $C_2O_3H_3$. The sum mentioned above is

$$12 \times 2 + 16 \times 3 + 1 \times 3 = 75$$

The molecular weight determined experimentally is 150. The integer multiple is 2 and the molecular formula becomes $C_4O_6H_6$.

The molecular weight of the compound can be obtained from the molecular formula by summing the products obtained by multiplication of the atomic weights of the elements times their subscripts in the molecular formula. The latter contains all the information that the empirical formula contains but in addition specifies the number of atoms in the molecule and also the molecular weight of the substance. The chemical formulae met in practice are molecular formulae.

Structural formulae have a twofold purpose: they attempt to show which atom is attached to which in the molecule and also to summarize the more important chemical reactions of the molecules. The cornerstone of the structural formula theory are the assumptions of definite valency for each element, the ability of certain atoms, especially carbon, to unite with each other to form chains and rings, and the formation of multiple valence bonds between atoms in a molecule. Most of the evidence for the manner in which atoms are attached to each other in the molecule is circumstantial. Yet all the circumstantial deductions of the organic chemist have been substantiated by direct evidence of spectroscopy The structural formula is also a shorthand notation for the important chemical reactions of the compound. It can be considered as being built up of a group of organic **radicals,** i.e., groups of atoms which retain their individuality in the course of certain reactions. Each radical has reactions which are characteristic of its presence in the molecule. For instance, the **carboxyl** radical $-\mathrm{C}(=\mathrm{O})-\mathrm{OH}$ will react with alkali such as **sodium** hydroxide to form salts $-\mathrm{C}(=\mathrm{O})-\mathrm{ONa}$, with **phosphorus** pentachloride to form acid **chlorides** $-\mathrm{C}(=\mathrm{O})-\mathrm{Cl}$; with **alcohols** to form **esters;** with reducing agents under certain conditions to form successively the **aldehyde** radical $-\mathrm{C}(=\mathrm{O})-\mathrm{H}$ and the **alco-**

hol radical. Any compound which undergoes such reactions is said to contain a carboxyl group. The number of such carboxyl groups in a molecule can be determined by studying the above reactions quantitatively. On the other hand if the compound will react with sodium to give off hydrogen; with phosphorus trichloride to give a halogen substitution product which can be reduced to **hydrocarbon**; with an oxidating agent to give an **aldehyde** or ketone, with organic **acids** to form **esters**; with **alcohols** to form **ethers**; then the molecule is said to contain a hydroxyl group —OH. Analogously there are similar characteristic reactions for a variety of radicals. It often happens that the presence of one type of a radical near another type mutually influences their reactivity, but one can consider to the first approximation that the radicals act independently of each other. The structural formula is considered completely established if one can synthesize the compound by simple clear-cut reactions involving no **rearrangments** on the basis of the proposed formula. In the particular example of tartaric acid the third step in the determination of the structural formula would be to determine what radicals are present in the molecule and their number. The results show that there are two carboxyl and two hydroxyl groups. The only structural formula involving these groups, satisfying valence requirements, possessing the proper molecular formula and consistent with the synthesis of tartaric acid is the following one

$$\begin{array}{c} O{=}C{-}OH \\ | \\ HC{-}OH \\ | \\ HC{-}OH \\ | \\ O{=}C{-}OH. \end{array}$$

To conclude, the structural formula purports to give an idea as to how the individual atoms are attached to each other in the molecule, to give a résumé of the chemical reactions, and to suggest methods of synthesis. Configurational formulae are discussed in **Isomerism and Stereoisomerism.** (R.K.S.)

CHEMICAL NOMENCLATURE AND PRONUNCIATION. Based on the "Report of the Commission on the Reform of the Nomenclature of Organic Chemistry," from the translation published in the Journal of the American Chemical Society, Vol. 55, No. 10, p. 3905, October, 1933.

The subject is treated under the following general headings: I. General. II. Hydrocarbons. 1. Saturated Hydrocarbons. 2. Unsaturated Hydrocarbons. 3. Cyclic Hydrocarbons. III. Fundamental Heterocyclic Compounds. IV. Simple Functions. V. Complex Functions. VI. Radicals. VII. Numbering.

I. General

1. As few changes as possible will be made in terminology universally adopted.

2. For the present, only the nomenclature of compounds of known constitution will be dealt with; the question of substances of imperfectly known constitution is postponed.

3. The precise form of words, endings, etc., prescribed in the rules should be adapted to the genius of each language by the subcommittees.

II. Hydrocarbons

4. The ending *ane* is adopted for saturated hydrocarbons. Open-chain hydrocarbons will have the generic name *alkanes.*

The name "alkane" is better and shorter than "paraffin," especially since the latter term is now so commonly applied to a solid mixture.

5. The present names of the first four normal saturated hydrocarbons (methane, ethane, propane, butane) are retained. Names derived from the Greek or Latin numerals will be used for those having more than four atoms of carbon.

6. Branched-chain hydrocarbons are regarded as derivatives of the normal hydrocarbons; their names will be referred to the longest normal chain present in the formula by adding to it the designations of the side chains. In case of ambiguity, or if a simpler name would result, that chain which admits of the maximum of substitutions will be selected as the fundamental chain.

If there are two or more choices for the longest chain, then that one should be chosen in which there is the greatest number of substitutions (the reason being that the substituting radicals, while more numerous, will be of simpler structure). Example:

$$\begin{array}{l} CH_3CH_2CH_2CH_2CHCH_2CH_2CH_2CH_3 \\ \qquad\qquad\qquad\quad | \\ \qquad\qquad\qquad\quad CH(CH_3)CH(CH_3)CH_3 \end{array}$$

By the principle of the "longest chain" the name would be 5-(1,2-dimethylpropyl)- nonane; but according to the rule the name 4-butyl-2,3-dimethyloctane (which avoids a branched side chain) is the one to be chosen if it seems simpler.

7. In case there are several side chains, the order in which such chains are named will correspond to the order of their complexity. The chain having the greatest number of secondary and tertiary atoms will be considered the most complex. The alphabetic order may also be followed in such cases.

8. In the names of open-chain unsaturated hydrocarbons having one double bond the ending *ane* of the corresponding saturated hydrocarbon will be replaced by the ending *ene;* if there are two double bonds, the ending will be *diene,* etc. These hydrocarbons will bear the generic names *alkenes, alkadienes, alkatrienes,* etc. Examples: propene, hexene, etc.

9. The names of triple-bond hydrocarbons will end in *yne, diyne,* etc. They will bear the generic name *alkynes.* Examples: propyne, heptyne, etc.

10. If there are both double and triple bonds in the fundamental chain the endings *enyne, dienyne,* etc., will be used. The generic names of these hydrocarbons will be *alkenynes, alkadienynes,* etc.

11. Saturated monocyclic hydrocarbons will take the names of the corresponding open-chain saturated hydrocarbons, preceded by the prefix *cyclo.* They will bear the generic name *cycloalkanes.*

12. When they are unsaturated, rules 8–10 will be applied. However, in the case of partially saturated polycyclic aromatic compounds the prefix *hydro,* preceded by *di-, tetra-,* etc., will be used. Example: dihydroanthracene.

13. Aromatic hydrocarbons will be denoted by the ending *ene* and will otherwise retain their customary names. However, the name *phene* may be used instead of *benzene.*

III. Fundamental Hetrocyclic Compounds

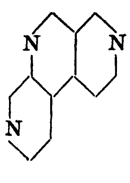
14. The endings of customary names, endings which do not correspond to the function of the substance, will undergo the following modifications, so far as they are in accord with the genius of each language: (a) The ending *ol* will be changed to *ole.* Example: pyrrole. (b) The ending *ane* will be changed to *an.* Example: pyran.

The change from *-ol* to *-ole* is obviously for the purpose of reserving -ol as an ending for the names of alcohols and phenols; similarly, the change from *-ane* to *-an* is made in order to reserve -ane for saturated parent compounds.

15. When nitrogenous heterocycles not having the ending *ine* give basic compounds on progressive hydro-

genation, such derivation will be indicated by the successive endings *ine, idine.* Examples: pyrrole, pyrroline, pyrrolidine; oxazole, oxazoline.

16. The ending *a* is adopted for hetero atoms occurring in a ring. Oxygen will accordingly be indicated by *oxa,* sulfur by *thia,* nitrogen by *aza,* etc. The letter *a* may be elided before a vowel. Examples: thiadiazole, oxadiazole, thiazine, oxazine.



While the universally accepted names of heterocyclic compounds are retained, the names of other heterocyclic compounds are derived from that of the corresponding homocyclic compound by adding to it the names of the hetero atoms ending in *a.* Example: 2,7,9-triazaphenanthrene.

IV. Simple Functions

17. Substances of simple function are defined as those containing a function of one kind only, which may be repeated several times in the same molecule.

That is to say, a compound which is an acid, an alcohol or an aldehyde and only that, is defined as a substance of simple function, while one which is at the same time an alcohol and an acid, or an acid and an aldehyde, is said to be a substance of complex function.

18. When there is only one functional group, the fundamental chain will be selected so as to contain this group. When there are several functional groups the fundamental chain will be selected so as to contain the maximum number of these groups.

19. Halogen derivatives will be designated by the name of the hydrocarbon from which they are derived, preceded by a prefix indicating the nature and number of the halogen atoms.

20. Alcohols and phenols will be given the name of the hydrocarbon from which they are derived, followed by the suffix *ol.* In accordance with rule 1 names universally adopted will be retained, as: phenol, cresol, naphthol, etc.

This nomenclature may also be applied to heterocyclics. Example: quinolinol.

21. In naming polyhydric alcohols or phenols, one of the forms *di, tri, tetra,* etc., will be inserted between the name of the parent hydrocarbon and the suffix *ol.* Example: CH_2OHCH_2OH, 1,2-ethanediol.

22. The name *mercaptan* as a suffix is abandoned; this function will be denoted by the suffix *thiol.* Examples CH_3SH, methanethiol; C_6H_5SH, benzenethiol; CH_2SHCH_2SH, 1,2-ethanedithiol.

23. Ethers are considered as hydrocarbons in which one or several hydrogen atoms are replaced by alkoxy groups. However, for symmetrical ethers the present nomenclature may be retained. Examples: $CH_3OC_2H_5$, methoxyethane; CH_3OCH_3, methoxymethane or methyl ether.

24. Oxygen linked, in a chain of carbon atoms, to two of these atoms will be denoted by the prefix *epoxy* in all cases where it would be unprofitable to name the substance as a cyclic compound. Examples: ethylene oxide = epoxyethane; epichlorohydrin = 3-chloro-1,2-epoxypropane; tetramethylene oxide = 1,4-epoxybutane.

25. Sulfides, disulfides, sulfoxides and sulfones will be named like the ethers, *oxy* being replaced by *thio, dithio, sulfinyl* and *sulfonyl,* respectively. Examples: $CH_3SO_2C_2H_5$ methysulfonylethane; $CH_3SC_3H_7$, methylthiopropane; $CH_3CH_2CH_2SOCH_2CH_2CH_2CH_3$, 1-(propylsulfinyl) butane.

26. Aldehydes are characterized by the suffix *al* added to the name of the hydrocarbon from which they are derived; thioaldehydes, by the suffix *thial.* Acetals will be named as 1,1-dialkoxyalkanes.

27. Ketones will receive the ending *one.* Diketones, triketones, thioketones will be designated by the suffixes *dione, trione, thione.*

28. The name *ketene* is retained.

"Ketene" (or, as spelled by some, "keten") is accordingly recognized as a name for the parent compound $CH_2{=}CO$.

29. For acids the rule of the Geneva nomenclature is retained. However, in cases where the use of that nomenclature would not be convenient the carboxyl group will be considered as a substituting group and the name of the acid will be formed by adding to the name of the hydrocarbon the suffix *carbonique* or *carboxylic,* according to the language.

30. Acids in which an atom of sulfur replaces an atom of oxygen will be named according to the Geneva nomenclature. Example: ethanethioic, -thiolic, -thionic, -thionothiolic. If the carboxyl is considered as a substituent the compounds will be named *carbothioic* acids. The suffix *carbothiolic* will be used if it is certain that the oxygen of the OH group is replaced by sulfur; the suffix *carbothionic* if it is the oxygen of the CO group; the suffix *carbodithioic* will be used if both oxygen atoms are replaced. Examples of the two systems of names: CH_3COSH or CH_3CSOH (either one), ethanethiolic acid, methanecarbothiolic acid; CH_3CSOH, ethanethionic acid, methanecarbothionic acid, CH_3CSSH, ethanethionothiolic acid, methanecarbodithioic acid.

31. The existing conventions will be retained for salts and esters. Examples: Sodium butanoate or sodium salt of butanoic acid; diethyl, 1,2-ethanedicarboxylate or diethyl ester of 1,2-ethanedicarboxylic acid; sodium acetate; methyl succinate.

32. Acid anhydrides will retain their present mode of designation according to the names of the corresponding acids. For names formed in accordance with the Geneva nomenclature, the amides, amidoximes, amidines, imides and nitriles will be named like the acids by adding to the name of the corresponding hydrocarbon the endings *amide, amidine, amidoxime, imide* and *nitrile,* respectively, while the halides will be named by combining *chloride,* etc., with the name of the radical. Examples: C_3H_7COCl, butanoyl chloride; $C_3H_7CONH_2$, butanamide; etc.

If the carboxyl is considered as a substituent the endings *carbonamide, carbonamidine, carbonamidoxime, carbonimide, carbonitrile* will be used. Examples: C_3H_7COCl, propanecarbonyl chloride; $C_3H_7CONH_2$, propanecarbonamide; etc.

33. The ending *ime* is reserved exclusively for nitrogenous bases. The present nomenclature of monoamines is retained. For polyamines, the name of the hydrocarbon will be followed by the suffixes *diamine, triamine,* etc.

For aliphatic compounds containing quinquivalent nitrogen the ending *ine* will be changed to *onium.* For cyclic substances containing quinquivalent nitrogen in the ring the ending *ine* will be changed to *inium;* for those with the ending *ole,* this will be changed to *olium.* Examples: pyridine, pyridinium; imidazole, imidazolium.

In accordance with the first sentence of this rule the spelling of names of non-bases ending in -ine should be changed; thus glycerine becomes glycerol, dextrine becomes dextrin, propine becomes propyne (see rule 9). Examples of names of amines: CH_3NH_2, methylamine; $(CH_3)_2NH$, dimethylamine; $(CH_3)_3N$, trimethylamine; $H_2NCH_2CH_2NH_2$, 1,2-ethanediamine; $C_6H_4(NH_2)_2$, benzenediamine.

34. The nomenclature of the derivatives of phosphorus, arsenic, antimony and bismuth, being very complicated, requires special consideration.

35. Oximes will be named by adding the suffix *oxime* to the name of the corresponding aldehyde, ketone or quinone. Examples: $C_2H_5ONH_2$, ethoxyamine; C_2H_5NHOH, ethylhydroxylamine.

36. The generic term *urea* is retained; it will be used as a suffix for the alkyl and acyl derivatives of urea. Examples: butylurea, $C_4H_9NHCONH_2$; butyrylurea,

$C_3H_7CONHCONH_2$. The bivalent radical —NHCONH— will be named *ureylene.*

37. The generic name *guanidine* is retained.

38. The name *carbylamine* is retained.

39. Isocyanic and isothiocyanic esters (RNCO, RNCS) will be named *isocyanates* and *isothiocyanates.*

40. The name *cyanate* is reserved for true esters which on saponification yield cyanic acid or its hydration products. The name *sulfocyanate* will be replaced by *thiocyanate.*

41. Nitro derivatives: no change in the present nomenclature. That is, the group NO_2 is always indicated by the prefix *nitro,* never by a suffix. Nitroso compounds are treated similarly (see rule 52). Examples: nitrosobenzene, 2,4,6-trinitrophenol.

42. Azo derivatives: the forms *azo, azoxy* are retained.

43. (a) Diazonium compounds, RN_2X, are named by addition of the suffix *diazonium* to the name of the parent substance (benzenediazonium chloride).

(b) Compounds having the same empirical formula but containing trivalent nitrogen will be named by replacing diazonium with *diazo* (benzenediazohydroxide).

(c) Substances of the type RN_2OM will be named *diazoates.*

(d) Compounds in which the two nitrogen atoms are united to a single carbon atom will be designated by the prefix *diazo* (diazomethane, diazoacetic acid).

44. Hydrazines are designated by the name of the alkyl radicals from which they are derived, followed by the suffix *hydrazine.* In cases where the amino group, of carbonamides is replaced by the hydrazino group, the suffix *hydrazide* will be used. Hydrazo derivatives are regarded as derivatives of hydrazine. Examples: CH_3NHNH_2, methylhydrazine; $C_2H_5NHNHC_3H_7$, 1-ethyl-2-propylhydrazine; $C_3H_7CONHNH_2$, butyrohydrazide or propanecarbohydrazide.

45. Hydrazones and semicarbazones are named like the oximes. The term *osazone* is retained.

46. The name *quinone* is retained.

47. Sulfonic and sulfinic acids will be designated by adding the suffixes *sulfonic* and *sulfinic* to the name of the hydrocarbon.

The analogous acids of selenium and tellurium will bear the names *alkaneselenonic* and *-seleninic* acids; *alkanetelluronic* and *-tellurinic* acids. Examples: $C_2H_5SO_3H$, ethanesulfonic acid; $C_{10}H_6(SO_2H)_2$, naphthalenedisulfinic acid.

48. Organometallic compounds will be designated by the names of the organic radicals united to the metal which they contain, followed by the name of the metal. Examples: dimethylzinc, tetraethyllead, methylmagnesium chloride.

However, if the metal is united in a complex manner it may be considered as a substituent. Example: $ClHgC_6H_4CO_2H$, chloromercuribenzoic acid.

49. The nomenclature of cyclic derivatives having side chains requires special consideration.

50. If it is necessary to avoid ambiguity, the names of complex radicals will be placed in parentheses. Examples: (dimethylphenyl)amine = $(CH_3)_2C_6H_3NH_2$; dimethylphenylamine = $C_6H_5N(CH_3)_2$.

V. Complex Functions

51. For compounds of complex function, that is to say, for compounds possessing different functions, only one kind of function (the principal function) will be expressed by the ending of the name. The other functions will be designated by appropriate prefixes.

52. The following prefixes and suffixes will be used for designating the functions.

Function	Prefix	Suffix
Acid and derivatives	carboxy	carbonylic, carbonyl, carbonamide, etc., or oic, oyl, etc.
Alcohol	hydroxy	ol
Aldehyde	oxo, aldo (for aldehyde O) or formyl (for CHO)	al
Amine	amino	amine
Azo derivative	azo	....
Azoxy derivative	azoxy	....
Carbonitrile (nitrile)	cyano	carbonitrile or nitrile
Double bond	....	ene
Ether	alkoxy	....
Ethylene oxide, etc.	epoxy	....
Halide	halogeno [halo]	....
Hydrazine	hydrazino	hydrazine
Ketone	oxo or keto	one
Mercaptan	mercapto	thiol
Nitro derivative	nitro	....
Nitroso derivative	nitroso	....
Quinquivalent nitrogen	....	onium, inium [olium]
Sulfide	alkylthio	....
Sulfinic derivative	sulfino	sulfinic
Sulfone	sulfonyl	..
Sulfonic derivative	sulfo	sulfonic
Sulfoxide	sulfinyl	...
Triple bond	...	yne
Urea	ureido	urea

For the order used in the *Chemical Abstracts* indexes, see Patterson and Curran, *Journal of the American Chemical Society,* **39,** 1624 (1917).

53. The names of derivatives of fundamental heterocyclic substances will be formed according to the preceding rules. Example: Hydroxyquinolinecarbonamide, not quinolinolcarbonamide.

VI. Radicals

54. Univalent radicals derived from saturated aliphatic hydrocarbons by removal of one atom of hydrogen will be named by replacing the ending *ane* of the hydrocarbon by the ending *yl.*

Examples: methyl, ethyl, pentyl (or amyl), etc. Since isopropylidene is recognized (rule 56) it was no doubt the intention of the Committee to recognize isopropyl similarly.

55. The names of univalent radicals derived from unsaturated aliphatic hydrocarbons will have the endings *enyl, ynyl, dienyl,* etc., the positions of the double or triple bonds being indicated by numerals or letters where necessary.

Examples: $CH_2{=}CH$—, ethenyl (or vinyl); $CH{\equiv}C$—, ethynyl; CH_3—$CH{=}CH$—CH_2—, 2-butenyl; $CH_2{=}CH$—$CH{=}CH$—, 1,3-butadienyl.

56. Bivalent or trivalent radicals derived from saturated hydrocarbons by removal of 2 or 3 hydrogen atoms from the same carbon atom will be named by replacing the ending *ane* of the hydrocarbon by the endings *ylidene* or *ylidyne.* For radicals derived from unsaturated hydrocarbons, these endings will be added to the name of the hydrocarbon. The names isopropylidene and methylene are retained.

57. The names of bivalent radicals derived from aliphatic hydrocarbons by removal of a hydrogen atom from each of the two terminal carbon atoms of the chain will be ethylene, trimethylene, tetramethylene, etc.

Only saturated radicals are provided for: —CH_2CH_2—, ethylene; —$CH_2CH_2CH_2$—, trimethylene, etc.

58. Radicals derived from acids by removal of OH will be named by changing the ending carboxylic to *carbonyl* or, if the Geneva nomenclature is used, oic to oyl. Examples: CH_3CO, ethanoyl or methanecarbonyl (or acetyl).

59. Univalent radicals derived from aromatic hydrocarbons by removal of a hydrogen atom from the ring

will in principle be named by changing the ending *ene* to *yl* However, the radicals C_6H_5 and $C_6H_5CH_2$ will continue provisionally to be named phenyl and benzyl, respectively. Moreover, certain abbreviations sanctioned by usage are authorized, as ***naphthyl*** instead of ***naphthalyl.*** Examples: $CH_3C_6H_4$—, tolyl (instead of toluyl), anthryl (instead of anthracyl), phenanthryl, fluoryl.

60. Univalent radicals derived from heterocyclic compounds by removal of hydrogen from the ring will be named by changing their endings to *yl.* In cases where this would give rise to ambiguity, merely the final *e* will be changed to *yl.* Examples: pyridine, pyridyl; indole, indoyl; pyrroline, pyrrolinyl; triazole, triazolyl; triazine, triazinyl.

61. Radicals formed by removal of a hydrogen atom from a side chain of a cyclic compound will be regarded as substituted aliphatic radicals. Examples: $C_6H_5CH_2CH_2$—, (2-phenylethyl); $C_6H_5CH{=}CHCH_2$—, (3-phenyl-2-propenyl).

62. In general, special names will not be given to multivalent radicals, derived from cyclic compounds by removal of several hydrogen atoms from the ring. In this case prefixes or suffixes will be used. Examples: triaminobenzene or benzenetriamine; dihydroxypyrrole or pyrrolediol.

63. The order in which prefixes or radicals are stated (alphabetic order or conventional order) remains optional.

VII. Numbering

64. In aliphatic compounds the carbon atoms of the fundamental chain will be numbered from one end to the other with the use of arabic numerals. In case of ambiguity the lowest numbers will be given (1) to the principal function, (2) to double bonds, (3) to triple bonds, (4) to atoms or radicals designated by prefixes. The expression "lowest numbers" signifies those that include the lowest individual number or numbers. Thus, 1,3,5 is lower than 2,4,6; 1,5,5 lower than 2,6,6; 1,2,5 lower than 1,4,5; 1,1,3,4 lower than 1,2,2,4. The Committee has left full latitude on the position of numbers.

65. Positions in a side chain will be designated by numerals or letters, starting from the point of attachment. The numerals or letters will be in parentheses with the name of the chain.

Examples: $(CH_3)_2CH$—, (1-methylethyl) or isopropyl; $CH_3CHClCH_2$—, (2-chloropropyl). The rule equally permits Greek letters, ordinary letters, primed numbers (1′, 2′), numbers with indices (4^1, 4^2) or other designations.

66. In case of ambiguity in the numbering of atoms or radicals designated by prefixes, the order will be that chosen for the prefixes before the name of the fundamental compound or side chain of which they are substituents.

67. The prefixes, *di, tri, tetra,* etc., will be used before simple expressions (for example, diethylbutanetriol) and the prefixes *bis, tris, tetrakis,* etc., before complex expressions. Examples: bis(methylamino)propane: $CH_3NH(CH_2)_3NHCH_3$; bis(dimethylamino)ethane, $(CH_3)_2NCH_2CH_2N(CH_3)_2$. The prefix *bi* will be used only to denote the doubling of a radical or compound; for example, biphenyl. (R.K.S.)

CHEMISTRY. On account of the vast scope of the field of chemistry, the subject has, for convenience, become divided into many branches. It should be emphasized that these branches are not, cannot be, and are not desired to be mutually exclusive. The field is a unit, covering the composition and changes in composition of matter, and the accompanying energy phenomena. The natural tendency is toward unification and removal of artificial barriers; the artificially created demand for systematic treatment has necessitated the erection of boundaries, but the more penetrable the boundaries, the better for the healthy unification and growth of science.

I. Classification of the subject, wherein the primary emphasis is on *Matter Changes.*

II. On *Energy Changes.*

A. *Inorganic Chemistry.* Study of chemical elements and their compounds, their properties, chemical behavior, preparation, and applications. List of elements accepted by the committee on Atomic Weights of the International Union of Chemistry:

Aluminum	**Fluorine**	**Mercury**	**Silicon**
(Ammonium)		**Molybdenum**	**Silver**
Antimony	**Gadolinium**		**Sodium**
Argon	**Gallium**	**Neodymium**	**Strontium**
Arsenic	**Germanium**	**Neon**	**Sulfur**
	Gold	**Nickel**	
Barium		**Nitrogen**	**Tantalum**
Beryllium	**Hafnium**		**Tellurium**
Bismuth	**Helium**	**Osmium**	**Terbium**
Boron	**Holmium**	**Oxygen**	**Thallium**
Bromine	**Hydrogen**		**Thorium**
		Palladium	**Thulium**
		Phosphorus	**Tin**
Cadmium	**Indium**	**Platinum**	**Titanium**
Calcium	**Iodine**	**Potassium**	**Tungsten**
Carbon	**Iridium**	**Praseodymium**	
Cerium	**Iron**	**Protactinium**	**Uranium**
Cesium			
Chlorine			
Chromium	**Krypton**	**Radium**	**Vanadium**
Cobalt		**Radon**	
Columbium	**Lanthanum**	**Rhenium**	**Xenon**
Copper	**Lead**	**Rhodium**	
	Lithium	**Rubidium**	**Ytterbium**
Dysprosium	**Lutecium**	**Ruthenium**	**Yttrium**
		Samarium	
Erbium	**Magnesium**	**Scandium**	**Zinc**
Europium	**Manganese**	**Selenium**	**Zirconium**

With the following exceptions the compounds of the above elements are treated in this book alphabetically by elements. The exceptions are in the cases of bromine, carbon, chlorine, fluorine, hydrogen, iodine, nitrogen, oxygen, phosphorus, sulfur, where the number and variety of substances to be discussed necessitates the extension of the discussion to additional separate articles. The titles of the articles related to each element are, however, stated under the given element.

B. *Organic Chemistry.* Among the chemical elements, carbon stands alone in the large number and complexity of its compounds. Carbon-containing substances are grouped and treated separately under the heading of organic chemistry. Traditionally, certain of these substances are commonly treated in inorganic chemistry, namely, the various forms of carbon element, carbon oxides, cyanogen, carbonic acid, formic acid, acetic acid, oxalic acid, hydrocyanic and related acids. The sections devoted to organic phases of chemistry are selected by topics, by important groups, and by individual substances. (See **Carbon, Key to Organic Compounds.**)

(a) Hydrocarbons.

(b) Oxygen function compounds. The following are found under **Oxygen**: Furane, pyrone; alcohols, phenols; aldehydes, ketones, quinones; carboxylic acids. The following are found in this book under their individual names:

Acetals	**Carbohydrates**	**Glucosides**
Acid anhydrides	**Cellulose**	
Aldehydeacids	**Coumarone**	**Hydroxyacids**
Anthocyanins		**Hydroxyaldehydes**
	Esters	**Hydroxyketones**
Benzil	**Ethers**	**Ketenes**
Benzoin	**Fats**	**Ketoneacids**

Lactones	**Phthaleins**	**Sugars**
Lactides		
	Saccharides	**Tannins**
Oils, fatty	**Starch**	
Oxides	**Sterols**	**Waxes**

(c) Nitrogen function compounds. The following are found under **Nitrogen**: Nitro-, nitroso-, hydroxylamines, hydrazines, amines; pyrrole, pyridine; amines; amides, cyanides and isocyanides; cyanates and isocyanates, ureas. **The following are found in this book under their individual names:**

Acridine	**Indazole**
Alkaloids	**Indigo**
Aminoacids	**Indole**
Aminoazo-compounds	**Isoquinoline**
Aminoguanidines	
Anilides	**Lactams**
Azides	**Lactims**
Azines	
Azo-compounds	**Nitrates**
Azoles	**Nitriles**
Azoxy-compounds	**Nitrites**
	Nitrobenzene
Biuret	**Nitrolic acids**
	Nucleic acids
Carbamic acid	
Carbazole	**Osazones**
Chlorophyll	**Oxazoles**
Cyanamides	**Oximes**
Cyanuric acid	
	Phenylhydrazones
Diazoamino-compounds	**Piperidine**
Diazo-compounds	**Polypeptides**
	Porphyrins
Esters	**Proteins**
	Purines
Fulminates	**Pyrazole**
	Pyrrolidine
Guanidines	
	Quinoline
Hydrazo-compounds	
Hydrazones	**Semicarbazides**
Hydrazoates	**Semicarbazones**
Hydroferricyanides	
Hydroferrocyanides	**Tetrazoles**
Hyponitrites	**Triazoles**
Hydroxyazo-compounds	
	Ureides
Imides	**Urethanes**
Imines	**Uric acid**

(d) Sulfur function compounds may be found by reference to the article on **Sulfur.** They include thiophene, penthiophene, thioalcohols, thiophenols, thioic acids, thiocyanates, thioureas, thiocarbonic acid, and related compounds; sulfinic acids, sulfinyl compounds, sulfonic acids, sulfonyl compounds.

C. *Analytical Chemistry.* Qualitative and quantitative analysis of elements, radicals and compounds, or by groups of these. (See **Analytical Chemistry.**)

D. *Synthetical Chemistry.* Qualitative and quantitative synthesis of compounds and radicals, or by groups of these.

E. *Principles of Chemistry*—Pure Chemistry. See below.

F. *Applications of Chemistry*—Applied Chemistry. See below.

G. *Radioactive changes* and ultimate structure of matter. (See **Radioactive Changes.**)

H. *Biochemistry.* Plant and animal substances and processes, both normal and abnormal. (See **Biochemistry.**)

I. *Geochemistry.* Composition of and changes in the atmosphere (see **Air**), hydrosphere (see **Water**), and lithosphere. By extension, astral chemistry. (See **Geochemistry.**)

J. *Domestic Chemistry.* Chemical aspects of air, **water, foods,** clothing, shelter, cleansing, transportation, communication, and sanitation.

K. *Agricultural Chemistry.* **Soils,** crops, **fertilizers,** agricultural **poisons** and live stock.

L. *Metallurgical Chemistry.* Recovery and purification of metals (see each metal), properties of metals and alloys.

M. *History and Evolution of Chemistry.* (See **History and Evolution of Chemistry.**)

N. *Studying and Teaching of Chemistry.*

O. *Chemical Nomenclature.* (See **Chemical Nomenclature.**)

The PRINCIPLES OF CHEMISTRY have been formed around various nuclei as the following arrangement illustrates:

(a) Matter in various physical states: (See *Each* of the following states of matter)
  (1) **Gases**
  (2) **Liquids**
  (3) **Solutions**
  (4) **Solids**
  (5) **Colloidal state**

(b) *Chemical composition* of matter: (See **Chemical Composition**)
  (1) Elements, symbols, atoms, allotropes, isotopes
  (2) Compounds, formulae, molecules, allotropes, isomers
  (3) Radicals
    (a) in combination
    (b) as ions (See **Reactions Involving Recombination of Ions**)
    (c) free
  (4) Equivalents, valency, graphical formulae

(c) Changes in composition of matter: (See **Chemical Changes**)
  (1) Reactions
    (a) Natural rates of reactions
      Concentration, temperature, pressure, medium
    (b) Artificially controlled rates of reactions
      Catalyzers
    (c) End-point of reactions—Equilibrium reactions
      Concentrations, equilibrium constant, temperature, pressure

(d) Changes in energy in chemical reactions.
  (1) **Thermochemistry**
  (2) **Electrochemistry**
  (3) **Photochemistry**

(e) Grand groups of chemical substances:
  (1) Acids, bases, salts (see **Reactions Involving Recombinations of Ions**)
  (2) Metals, non-metals, alloys
  (3) Oxides, chlorides, sulfides (see each; **Thermochemistry, Heat of Formation**)
  (4) Organic (classification given on preceding pages)

(f) Grand groups of chemical reactions
  (1) **Reactions involving recombinations of Ions**—Hydrogen-ion concentration; pH; indicators
  (2) **Reactions involving water**
    (a) Consumption of water—including acid and alkaline mediums—Hydrolysis; saponification of esters
    (b) Production of water—Neutralization; esterification; nitration; sulfonation
    (c) Water as catalyzer
  (3) **Reactions involving oxidation—reduction**

(a) In solutions of electrolytes
(b) Not in solutions of electrolytes, including oxygenation and deoxygenation; hydrogenation and dehydrogenation; chlorination and dechlorination; bromination and debromination; nitro-reduction; and sulfonyl-reduction

(4) **Würtz-Fittig**—sodium-organic halide reaction

(5) **Friedel-Crafts** — anhydrous aluminum chloride-alkyl-aryl halide-benzenoid hydrocarbon reaction

(g) Grand groups of phenomena and processes:

(1) Isotopy (see **Chemical Composition**); allotropy (see **Chemical Composition**); **Isomerism and Stereoisomerism**

(2) **Association and Polymerization; Dissociation; Rearrangement; Passivity**

(3) Role of water; **deliquescence; efflorescence**; desiccation; drying; water as catalyzer (see **Reactions Involving Water**)

(4) **Equilibrium** including Phase rule

(5) **Adsorption**

(6) Vapor pressure

(7) Heating of materials
(a) With access of air: roasting (see **Calcination**); smelting
(b) Without access of air: **calcination; destructive distillation**; sublimation; **distillation, evaporation and drying** (see **Distillation**)

(8) Solid-liquid-gas treatments
Including precipitation; crystallization; sedimentation; filtration; dissolving solids; extraction

APPLICATIONS OF CHEMISTRY. Applied chemistry both industrial and non-industrial, concerned with (1) chemical materials, their composition, location, transportation, storage, (2) chemical processes naturally occurring or artificially operated, their matter and energy changes, the conditions, both favorable and unfavorable, of temperature, pressure, concentration, medium and catalyzer for these changes to take place, including apparatus, (3) chemical products, their quality (composition or specifications), quantity, applications, uses, and value.

Industrial chemistry, including chemical engineering, economic aspects of chemistry plus industry, embraces a part of the field of applied chemistry. Those product industries which have attained large proportions and general recognition are among the following:

Abrasives
Acetaldehyde
Acetic acid
Acetone
Acetylene
Acids. (See individual acids, e.g., **sulfuric, nitric, hydrochloric, phosphoric, oxalic, phthalic.**)
Adhesives
Alcohols
Alkalis. (See individual alkalis, e.g., **sodium** hydroxide and carbonates, **potassium** hydroxide and carbonates, **ammonium** hydroxide, **calcium** oxide and carbonate.)
Alloys
Aluminum and its compounds
Amines
Ammonia
Ammonium compounds
Aniline
Anthracene
Arsenic compounds
Artificial fibers and films. (See **Carbohydrates.**)

Baking powders
Barium compounds
Benzene
Bleaching substances, bleaching and decolorizing
Boron compounds
Bricks. (See **Ceramics.**)
Bromine and its compounds

Calcium compounds
Carbon dioxide
Casein. (See **Aminoacids; Plastics.**)
Cellulose. (See **Carbohydrates.**)
Cement, Portland
Ceramics
Chlorine and its compounds
Chromium and its compounds
Coal. (See **Fuels; Destructive distillation** products; **Hydrogenation.**)
Coal Tar products and intermediates
Coke. (See **Fuels; Destructive distillation** products; **Calcium** carbide.)
Copper and its compounds

Decolorizing. (See **Bleaching** substances.)
Destructive distillation products
Dextrin. (See **Carbohydrates; Adhesives.**)
Disinfectants. (See **Poisons.**)
Drugs
Dyes and dyeing, textile fibers

Earthenware. (See **Ceramics.**)
Essential Oils. (See **Hydrocarbons,** terpenes.)
Esters
Ethers. (See **Alcohols.**)
Ethyl alcohol
Explosives

Fats. (See **Esters.**)
Fertilizers
Flavors. (See **Esters.**)
Foods
Formaldehyde
Fuels
Fungicides. (See **Poisons.**)

Gases. (See individual gases, e.g., **oxygen, acetylene, ammonia, chlorine, carbon dioxide, hydrogen, nitrous oxide, sulfur dioxide; Fuels.**)
Gasoline. (See **Hydrocarbons,** paraffin.)
Germicides. (See **Poisons.**)
Glass
Glazes. (See **Glass.**)
Glycerol
Gold and its compounds

Hydrochloric acid
Hydrogen
Hydrogenation products. (See **Catalysis; Hydrogenation.**)

Inks. (See **Tannins.**)
Intermediates. (See **Coal Tar** products.)
Insecticides. (See **Poisons.**)
Iron and its compounds.

Ketones. (See **Aldehydes.**)

Lead and its compounds
Leather and tanning. (See **Tannins.**)
Lime. (See **Calcium** oxide.)
Lubricants

Magnesium and its compounds
Mercury and its compounds
Metals. (See individual metals, e.g., **iron, copper, lead, zinc, aluminum, magnesium, nickel, tin, mercury, silver, gold.**)
Methyl alcohol

Naphthalene
Nickel and its compounds
Nitric acid
Nitrobenzene
Nitrocellulose. (See **Explosives.**)
Nitrogen and its compounds. (See also **Fertilizers; Explosives.**)
Nitroglycerine. (See **Explosives.**)
Nitrous oxide. (See **Nitrogen,** oxides.)

Oils. (See **Esters** for fatty oils; **Hydrocarbons,** for petroleum products, and for essential oils.)
Oxalic acid
Oxygen

Paints. (See **Pigments.**)
Perfumes
Petroleum. (See **Hydrocarbons,** paraffin.)
Phenol
Phosphate rock. (See **Phosphoric acid; Fertilizers.**)
Phosphoric acid
Phosphorus and its compounds
Photography
Phthalic acid
Pigments
Plaster. (See **Calcium** sulfate.)
Plastics
Poisons
Potassium compounds. (See also **Fertilizers.**)
Pottery. (See **Ceramics.**)

Rayon. (See **Carbohydrates.**)
Refractories
Rubber and accelerators

Salts. (See individual salts.)
Silica. (See **Silicon,** oxide)
Silver and its compounds
Slags. (See **Glass.**)
Soaps. (See **Esters.**)
Sodium compounds
Solvents
Starch. (See **Carbohydrates.**)
Steel. (See **Iron.**)
Stoneware. (See **Ceramics.**)
Sugars. (See **Carbohydrates.**)
Sulfur and its compounds
Sulfur dioxide. (See **Sulfur,** oxides.)
Sulfuric acid

Textile fibers. (See **Dyes.**)
Tiles. (See **Ceramics.**)
Tin and its compounds
Toluene
Turpentine. (See **Hydrocarbons,** Terpenes.)

Varnishes. (See **Pigments.**)

Waxes. (See **Esters.**)

Zinc and its compounds. (R.K.S.)

CHEMORECEPTOR. Sense Organ.

CHERRY. Rose Family.

CHERT. An impure, flinty hard rock composed chiefly of cryptocrystalline **silica.** Chert varies in color from gray through brown to black according to the kind and amount of coloring matter. It occurs principally as concretions, nodules or bands in **limestones** and **dolomites,** and unlike **flint** its fracture tends to be splintery instead of conchoidal. A great deal has been written on the occurrence and origin of chert and there is no doubt but that it may be formed in several different ways. Many of the nodular and concretionary cherts have grown around siliceous sponge spicules or **radiolaria.** Chert may be either **sygenetic** or **epigenetic.** The former type is supposed by some authors to be chemically precipitated from river waters on the bottom of the sea as a colloid contemporaneously with the limestones or dolomites. On the other hand certain cherts are obviously secondary although they may have been formed previous to the final lithification of the formations in which they occur. Cherts which contain relatively large amounts of iron are called **Jasper.** (R.M.F.)

CHESTNUT BLIGHT. Ascomycetes.

CHEVROTAIN. Mammalia, Artiodactyla. The mouse-deer of Asia and Africa, a group of several species whose appearance is like that of very small **deer** but whose structure differs in several important details. *Tragulus* is found in Asia, *Dorcatherium* in Africa. (A.W.L.)

CHEWING GUM. Achras Sapota.

CHEZY FORMULA. The Chezy formula is an important formula for friction loss in large water conduits. The formula is stated as follows:

$$V = C\sqrt{RS}.$$

R is the **hydraulic radius** of the cross-section of flow. It is the cross-sectional area of flow divided by the wetted perimeter. S is the friction loss, in fractional foot head per ft. length of conduit for a conduit running full of water, or it is the slope of the water surface, fractional foot per ft. of length for open flow. C is a coefficient. A widely accepted formula for C is Kutter's formula, as follows:

$$C = \frac{41.65 + \frac{1.811}{n} + \frac{.00281}{S}}{1 + \frac{n}{\sqrt{R}}\left(41.65 + \frac{.00281}{S}\right)}.$$

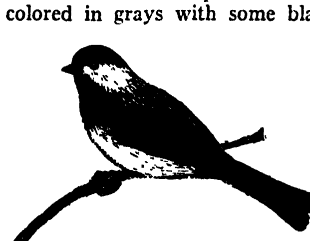
In this formula, R and S have meanings already defined, n is a channel roughness coefficient. Typical values of n are as follows:

Wood stave penstocks	.010
Steel penstocks .	.017
Lumber flumes	.014
Earth canal	.030
Natural river channel	.05 to .10

The original expression for C of the Kutter formula did not contain the term in S. It is said that this term was inserted at a later date to make the Chezy formula give results consistent with actual data for the very flat slopes of the Mississippi River where slopes as flat as ⅕″ per mi. were encountered. For normal use the term in S has little effect on results computed by the formula. (E.W.S.)

CHIASTOLITE. Andalusite.

CHICKADEE. Aves, Passeriformes. Birds (**Aves**) of several species found in various parts of North America, all quietly colored in grays with some black markings



Carolina Chickadee.

and in some species a little white and brown. The common widely distributed species is also called the black-capped **titmouse,** *Penthestes atricapillus.* (A.W.L.)

CHICKENPOX (Varicella). A common highly contagious disease of childhood caused by a filterable **virus.** The disease has been distinguished from smallpox since 1553. It is spread by direct contact, the incubation period being 14 to 16 days.

In children the disease is usually quite mild. The first symptom is often the eruption which begins on the face or trunk as small, red, widely scattered itchy spots, and spreads to the rest of the body, including the scalp and **mucous membranes** of the mouth and **pharynx.** The eruption is often most abundant on the neck and shoulders. The red spots increase in size and soon are capped by small blisters of clear fluid, which progress to scab formation. The rash characteristically appears in crops over a period of 3–4 days so that early and late lesions may be seen side by side. A fever up to 101° F. may be present during the first day or two. Usually, if not infected by scratching, the lesions heal without leaving scars.

In adults, chickenpox is often a more serious disease, with severe systemic reactions and high fever.

Treatment is supportive. The patient should be isolated, and efforts made to prevent secondary infection. (D.M.H.)

CHICLE. Achras Sapota.

CHICORY. Cichorium Intybus. Composite Family.

CHIGGER, CHIGOE, JIGGER. 1. Arachnida, Acarina. A harvest **mite** whose **larva** is very irritating to the human skin, causing intense itching. North American, sometimes locally abundant. 2. Insecta, Siphonaptera. A small **flea** found in the tropical parts of Africa and the New World. After mating the female burrows into the skin of a warm-blooded animal and becomes distended as her eggs develop until she is as large as a pea. When they attack man they usually enter the skin of the foot and cause a troublesome sore. (A.W.L.)

CHILARIA. A pair of rudimentary appendages on the first abdominal or pregenital segment in the king crab (**Xiphosura**). (A.W.L.)

CHILBLAIN. Inflammation, accompanied by swelling, painfulness, itching, and redness of the hands or feet due to exposure to cold. (D.M.H.)

CHILDBED FEVER. Puerperal Sepsis.

CHILDRENITE. The mineral childrenite is a complex hydrous compound of **aluminum, iron** and **phosphorus. Manganese** may replace the **iron,** this variety being called **eosphorite.** Childrenite is known only in **orthorhombic** crystals; massive sorts have never been found. Its hardness is 4.5–5; specific gravity, 3.18–3.24; luster, vitreous to resinous; color, pale yellowish through yellowish-brown to nearly black; streak is white or yellowish; translucent. Childrenite is found in Saxony; Devonshire, England; and Oxford County, Maine. Eosphorite occurs in Branchville, Connecticut; Oxford County, Maine, and Bavaria Childrenite was named for J. G. Children, an English mineralogist. Eosphorite is derived from the Greek word meaning dawn-bearing, because of the pinkish color of this mineral. (E.S.C.S.)

CHILL. A paroxysm of shaking or shivering, accompanied by a sense of cold and pallor of the skin. During a severe chill the temperature becomes elevated. A chill may indicate the onset of a disease, often a severe infection, notably lobar **pneumonia** and **malaria.**

Nervous chill is shaking or shivering due to excitement, fear, or anger, and is not accompanied by any rise in temperature. (D.M.H.)

CHILOPODA. The centipedes, usually considered as a class of arthropods related to but distinct from the millipedes and a few rare forms, but sometimes ranked as an order in the class Myriapoda, containing all of these forms.

These animals are elongate and slender with numerous segments, most of them bearing a single pair of appendages. They have one pair of **antennae** and the first pair of legs is modified to form a pair of poison claws with which they catch their prey. They are terrestrial, breathing by air tubes (**tracheae**) which open separately on the various segments. The body is flattened and the segments are composed of dorsal and ventral plates connected by softer lateral walls which bear the legs. Centipedes have poison glands opening through the poison claws but there is no evidence to show that they are ever dangerous to man. (A.W.L.)

CHIMACHIMA. Aves, Falconiformes. A bird (**Aves**) of prey found from Panama to southern Brazil. One of the **caracaras.** (A.W.L.)

CHIMANGO. Aves, Falconiformes. A South American bird (**Aves**) of prey found in Tierra del Fuego and the southern part of the continent. A **caracara.** (A.W.L.)

CHIMNEY. A chimney is a vertical tubular structure of masonry, steel, or reinforced concrete, built for the purpose of enclosing a column of hot gas, to produce thereby a draft. Combustion requires **oxygen.** Air is needed to supply it. To move this air through the fuel bed, and to produce a flow of the gaseous products of combustion through the furnace and boiler, or through a stove, requires a difference of pressure, called draft. The chimney is built primarily to produce a certain available draft, although sometimes a chimney may have to be high for reasons entirely foreign to draft. In addition to the useful draft it produces, a chimney must also overcome the friction loss in the chimney itself. These losses are proportional to the cross-sectional area of the stack. Hence the problem of chimney diameter is more than the assumption of a velocity comparable to that used in actual practice; it should be such that the diameter and height it indicates result in a chimney of least cost. Ordinarily, the economic chimney gas velocities range between 20 and 40 ft. per sec.

A chimney produces a draft by virtue of an extremely simple principle of thermodynamics. When gas is heated it expands in volume and decreases in density, in which condition it may be displaced by a more dense gas. The light, hot flue gas is confined by the chimney. The tendency of hot gas to move up the chimney is proportional to the height of the stack, since the difference of weight of equivalent columns of air and flue gas (and this is the draft) is greater the higher the columns.

The draft of a stack is, in an elementary way, expressed by:

$$D = \text{Height multiplied by difference in density of flue gas and air.}$$

Many empirical formulae are advanced for computing the height of a chimney required for a given boiler. A rational scientific approach would necessarily be based on the above equation, as it truly represents the physical action actually creating the draft. When the elementary equation is written for a chimney of 100 ft. incorporating certain factors needed to convert draft to inches of water, and allowing for cooling and friction in the stack, it has the form:

$$D = K(d_a - d_f) - 0.0148 d_f \sqrt{\frac{V^5}{F}}$$

where D = effective draft per 100 ft. of stack, in inches of water.
K = 17.3 for masonry stacks, and 15.4 for steel stacks.
d_a = density of air, in pounds per cubic foot.
d_f = density of flue gas, in pounds per cubic foot.
V = gas velocity in the stack, in feet per second.
F = gas flow, in cubic feet per second.

The second term in this equation allows for friction in the stack itself, so that D represents the effective draft per 100 ft. of stack. The actual height of a chimney is obtained by dividing required draft by D and multiplying by 100. The required stack draft is the sum of all friction losses external to the stack, plus the impact loss (of gas discharged from stack), and less the effective draft furnished by fans or jets. The impact loss is $0.003V^2d_f$ in. of water, the symbols having meaning as given above.

The use of perforated radial bricks has found much favor in chimney construction. Their dead air space acts somewhat as heat insulation, and they are lighter than ordinary bricks. Comparatively short stacks are frequently made of plate steel. These are lined for a portion of their height with refractory lining, and, unless very short, are braced by suitable guy wires. A tall masonry chimney must have sufficient area in any transverse section to distribute the superimposed weight sufficiently to prevent the unit pressure from exceeding the safe bearing power of the masonry material. The effect of a transverse applied load due to wind pressure cannot be neglected. The effect of wind pressure is to increase the compression in the masonry on the leeward side and decrease it on the windward side. Since tension is not permissible in masonry, not only the thickness of the wall, but the external diameter of the chimney, must be selected with due respect to strength and stability under the condition of maximum wind load. It is very important that the foundation of a tall chimney be absolutely firm and unyielding, as a very small settling on one side would throw the top of a tall chimney several inches out of line and induce an unexpected eccentric loading in the structure.

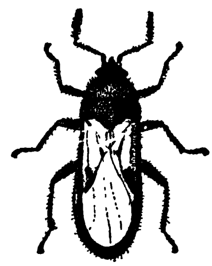
To be satisfactory, chimneys for residences must, like all other chimneys, have sufficient height for the required draft, and sufficient area to carry off the volume of gases produced. Deficiencies in either or both of these needed characteristics will be sure to cause lazy fires and smoky furnaces. Insofar as possible, a chimney should be straight and perpendicular. Necessary bends should be reduced to the minimum, and corners should be well rounded. The use of a flue lining made of jointed sections of tile is an aid to draft as well as a safeguard against the risk of fire due to defective brickwork in the chimney. (F.T.M.)

CHIMPANZEE. Mammalia, Primates. One of the large man-like **apes** of tropical Africa. This species has been found the most easily kept and tractable of the apes in captivity and for this reason has been a favorite subject for the study of these near relatives of the human species. A number of chimpanzees have become famous for their ability to learn human habits and have displayed the rudiments of true intelligence. (A.W.L.)

CHINA-CLAY. A commercial term, more or less identical with **kaolin,** as applied to the relatively pure clay concentrated by washing from a thoroughly kaolinized **granite.** England is the chief exporter of China-clay. France has unique clays from which are made the famous Sèvres and Limoges potteries. At the present time the United States imports only about ⅓ of the China-clay which it consumes, most of its domestic supply coming from the **Cretaceous** clays of New Jersey. (R.M.F.)

CHINAWOOD OIL. Esters.

CHINCH BUG. Insecta, Hemiptera. A small black bug, *Blissus leucopterus,* with whitish wing membranes. Although its total length is only ¼″ it is one of the most serious pests of wheat and damages other cereals as well. The methods of control are complex, including means of trapping the bugs during migration from field to field, the destruction of rubbish in which they spend the winter, and the use of decoy plots planted at such a time as to be most attractive when the eggs are being deposited. These plots are later plowed under to destroy the insects. (A.W.L.)



Chinch bug.

CHINCHILLA. Mammalia, Rodentia. Small squirrel-like **rodents** related to the porcupines. They live at high altitudes in the mountains of South America. The fur of the common chinchilla is valuable. There are two genera, *Chinchilla* and *Lagidium.* (A.W.L.)

CHINE. Seaplane.

CHINOOK. Pisces, Teleostei. The king or quinnat **salmon,** most important of all North American food fishes. It is found from California to Alaska.

In meteorology, a warm wind blowing down the east slopes of the Rockies. It is similar to the **foehn wind.** (A.W.L., P.E.K.)

CHIP. Cutters.

CHIPMUNK. Mammalia, Rodentia. Small burrowing **rodents** of squirrel-like appearance but with the tail shorter and not bushy. They are brown or grayish with longitudinal stripes on the back or sides. They are omnivorous and while not usually troublesome they sometimes destroy flowering bulbs during the winter.

Chipmunks belong to several genera and numerous species and subspecies. Some of the western species are called golden chipmunks or rock squirrels and others antelope chipmunks or ground squirrels. They are related to the ground squirrels and gophers. While predominantly North American, chipmunks are also found in Siberia. (A.W.L.)

CHIROPTERA. The **bats.** An order of mammals highly specialized for flying. (A.W.L.)

CHIRU. Mammalia, Artiodactyla. The Tibetan **antelope,** *Panthalops hodssoni,* a species of moderate size with long horns, ringed in the basal half. (A.W.L.)

CHISEL. Lathe, Woodworking.

CHISEL-JAW. Pisces, Teleostei. A small fish (**Pisces**) of West African rivers. It has very strong teeth. (A.W.L.)

CHISEL-MOUTH. Pisces, Teleostei. A North American fish (**Pisces**), *Acrocheilus alutaceus,* related to the carps and dace, found in the lower Columbia River and its tributaries. (A.W.L.)

CHI-SQUARE. Chi-square, χ^2, is defined

$$\chi^2 = \sum \frac{(f_o - f_t)^2}{f_t}$$

where f_o is the observed frequency and f_t is the theoretical frequency calculated in accordance with the hypothesis which is being tested. The summation extends over all classes. (L.A.A.)

CHI-SQUARE PROBABILITY FUNCTION. The chi-square **probability function** is fundamental in modern **statistics.** Its equation is

$$P_{\chi^2}\, d\chi^2 = \frac{1}{\Gamma\left(\frac{n}{2}\right)} e^{-\frac{\chi^2}{2}} \left(\frac{\chi^2}{2}\right)^{\frac{n}{2}-1} d\left(\frac{\chi^2}{2}\right), \quad 0 \leq \chi^2 < \infty.$$

The χ^2 test of goodness of fit and the χ^2 test of independence in contingency tables depend upon it. Confidence limits for the population variances, when the variates are normally distributed, are based upon it also. In addition, it has many other uses. The χ^2 distribution is a special case of **Pearson's Type III function.** It contains only one parameter n, the **degrees of freedom.** The expected value of χ^2 is n, its variance $2n$, and its measure of **skewness** $\alpha^2{}_{3:\chi^2} = 8/n$. Tables of the probability levels of the χ^2 distribution are readily available. (L.A.A.)

CHI-SQUARE TEST OF GOODNESS OF FIT. The χ^2 test of goodness of fit is used to test the hypothesis that a **sample** arose from a given **population.** The actual frequencies are compared with the theoretical frequency by means of **chi-square**

$$\chi^2 = \sum \frac{(f_o - f_t)^2}{f_t}.$$

If χ^2 is "large" it is assumed that the hypothesis is not tenable. Just how large χ^2 should be to reject the hypothesis is determined by the χ^2 distribution and the level of significance adopted, such as the 5% or 1% level. In most applications the theoretical frequency f_t should be 5 or more. Furthermore, the degrees of freedom n must be determined in using the χ^2 table, where the degrees of freedom equal the number of classes whose theoretical frequency is 5 or more less the number of **statistics** used in finding the theoretical frequencies less 1. Essentially the same methods are used in testing **contingency tables** for independence. (L.A.A.)

CHITAL. Mammalia, Artiodactyla. The Indian spotted **deer** or axis deer, *Axis axis.* (A.W.L.)

CHITIN. An essential constituent of the **cuticula** of **arthropods.** Also found to a lesser extent in most of the invertebrate groups. A material of variable and intricate chemical composition, this substance has been the subject of habitual misstatement especially among entomologists. It is a principal component of the insect exoskeleton and appears in both the rigid and flexible parts, which are usually said to be chitinized or not chitinized; the degree of rigidity has recently been said to depend upon other materials deposited with the chitin. Chitin is inelastic, hence the arthropods shed the exoskeleton at intervals during growth to permit expansion during the formation of a new covering. Chitin is chemically very inactive. (A.W.L.)

CHITRA. **Chital.**

CHIVES. **Allium.**

CHLAMYDOSPORE. A single spore or reproductive cell enclosed in a spore case, formed by some of the **slime molds.** (A.W.L.)

CHLOANTHITE. **Smaltite-Chloanthit.**

CHLORAL HYDRATE ($CCl_3 \cdot CHO \cdot H_2O$). A valuable and powerful sedative prepared by passing chlorine gas through absolute alcohol (see **Ethyl Alcohol**) and precipitating with water. It occurs in crystalline form, is soluble in water, has a bitter caustic taste and penetrating odor.

With therapeutic doses, quietness and drowsiness are produced. Pain is not diminished. With poisonous doses there is profound stupor, coma and collapse which may result fatally.

Chloral should never be given with alcohol as the alcoholic solution which is formed constitutes the well-known powerful "knockout drops," a quick-acting and dangerous depressant.

Chloral is used medically to quiet nervousness, irritability, and to produce sleep. It is contraindicated in threatened failure of the circulation or respiration or in the presence of marked liver, kidney, or heart disease. (See **Acetaldehyde** and **Drugs.**) (D.M.H.)

CHLORENCHYMA CELLS. **Parenchyma.**

CHLORIC ACID AND CHLORATES. Chloric acid ($HClO_3$) is a colorless solution; fairly stable but slowly decomposes into (a) **perchloric** and **hydrochloric acids,** (b) chlorine dioxide and **oxygen,** (c) hydrochloric acid and oxygen, (d) **chlorine** and oxygen (when of strength as high as 40% $HClO_3$). Can be concentrated in vacuum up to 52% $HClO_3$ with considerable decomposition. A powerful oxidizing agent, e.g., **sulfur** and all forms of sulfur compounds (other than **sulfates**) to **sulfuric acid**—but **persulfates** oxidize chlorate to perchlorate.

Prepared by reaction (1) of **barium** chlorate solution and sulfuric acid, and filtering off barium sulfate, (2) **potassium** or **sodium** chlorate and sulfuric acid.

Potassium chlorate is formed (1) by electrolysis of potassium chloride solution, stirring and heating over some hours, (2) by heating potassium hypochlorite solution.

Metallic chlorates are solids, soluble in water, except that those of bismuth, tin and mercury require a little free acid. Chlorates, when heated, evolve oxygen and leave the chloride (or oxide) as residue. The process of evolution of oxygen from chlorates liberates heat and may take place with explosive violence. The addition of a **catalyzer,** e.g., **manganese** dioxide, causes a rapid evolution of oxygen at the melting point of the chlorate. Potassium chlorate explodes violently, upon friction or percussion, with sulfur, phosphorus, charcoal, sugar and many organic substances. When potassium chlorate (melting point about 350° C.) or sodium chlorate (melting point 260° C.) is heated for some time somewhat above the melting point, the respective perchlorates and chlorides are formed.

Upon addition of hydrochloric acid, chlorate liberates chloric acid, which reacts with hydrochloric acid to form chlorine. (R.K.S.)

CHLORIDE. **Chlorine.**

CHLORINE. Symbol: Cl. Atomic number: 17. Atomic weight: 35.457. Density: 3.214 grams per liter, 0° C., 760 mm. or 2.486 when air equals 1.000. Formula of chlorine gas: Cl_2. Melting point: —100.6° C. Boiling point: —34.6° C. Critical temperature: 144.0° C. Critical pressure: 76.1 atmospheres. Isotopes: 35 (76%), 37 (24%), have been separated by diffusion, and have been identified and quantitatively estimated by the mass spectroscope.

Chlorine is a pale greenish-yellow gas, of marked odor, irritating to the eyes and throat, poisonous. Somewhat soluble in water, soluble in carbon tetrachloride to a colorless solution. Discovered by Scheele in 1774, but identified as a chemical element by Davy in 1810.

Chlorine occurs as sodium chloride in ocean water (2% Cl), in salt beds, salt brines, salt lakes, e.g., Stassfurt, Germany, the Dead Sea, the states of New York, Michigan, Louisiana, Utah, and many other places. Practically all the chlorine manufactured in the United States is made by electrolysis of sodium chloride solution under special conditions. Chlorine is marketed as liquid in steel cylinders up to large sizes, or as "bleaching powder" (calcium hypochlorite) or as sodium hypochlorite, and is used (1) for the purification of drinking water, (2) as a disinfectant, (3) in the preparation of many chemicals, (4) for bleaching paper pulp and textiles.

Chlorine does not react with oxygen gas, but is reactive with explosive violence with **hydrogen** gas when exposed to sunlight; reacts vigorously with many metals such as **copper, iron, aluminum, arsenic, antimony;**

with some non-metals such as **phosphorus, sulfur;** with many organic compounds such as **ethylene, acetylene** to form ethylene dichloride, acetylene tetrachloride, respectively, with warm **turpentine** to form **carbon** plus **hydrogen chloride** violently, with benzenoid compounds to form chloro-benzenoid substitution products plus hydrogen chloride. Chlorine reacts with **sulfurous acid** to form **sulfuric acid;** with **hydrosulfuric** acid in deficiency of chlorine to form **sulfur,** in excess of chlorine to form sulfuric acid.

Azide: Chlorazide (ClN_3).

Acids: Hydrochloric acid (HCl); hypochlorous acid (HOCl); chlorous acid ($HClO_2$); chloric acid ($HClO_3$); perchloric acid ($HClO_4$). See each acid. Also chloro-organic acids, see below.

Bromide: Chlorine bromide (ClBr).

Chlorate: (See **Chloric Acid.**)

Chlorides: Chlorides are known of many elements. Metallic chlorides are (1) Soluble, e.g., **sodium, potassium, ammonium** chlorides (NaCl, KCl, NH_4Cl); (2) Reactive with water, e.g., **aluminum** chloride anhydrous, **magnesium** chloride crystals when heated, titanium tetrachloride, **stannic** chloride anhydrous; (3) Insoluble, e.g., **silver** chloride (AgCl), **lead** chloride ($PbCl_2$) (soluble in hot water), **mercurous** chloride (HgCl); and (4) organic chlorides are noteworthy, e.g., methyl chloride (chloromethane, CH_3Cl), chlorobenzene (phenyl chloride, C_6H_5Cl), carbon tetrachloride (CCl_4), carbonyl chloride ("phosgene," $COCl_2$). Hydrochloric acid and soluble chlorides are important chemical reagents for the precipitation of insoluble chlorides. (See **Hydrochloric Acid.**) Organic chloro-compounds, see Chlorine, organic compounds, below.

Chlorites: (See **Chlorous Acid.**)

Hydride: Hydrogen chloride (HCl), colorless gas, of characteristic odor, melting point —111° C., boiling point —85° C., density 1.27 (air equal to 1.00), very soluble in water yielding **hydrochloric acid.** Formed by reaction of (1) sodium chloride and concentrated sulfuric acid upon heating, (2) hydrogen and chlorine gases under regulated conditions (explosive in sunlight or magnesium light). Reacts with ammonia gas to yield ammonium chloride, white smoke.

Hypochlorites: (See **Hypochlorous Acid.**)

Iodides: Chlorine iodide (ClI); trichloroiodine (Cl_3I).

Oxides: Chlorine monoxide (Cl_2O), pale orange-yellow gas, boiling point 5° C., odor resembling but distinguishable from chlorine, soluble in water to yield hypochlorous acid, reactive with explosive violence with sulfur, phosphorus, and many carbon compounds. Formed (Hazard!) by reaction (1) of chlorine gas and dry finely divided mercuric oxide at 400° C., (2) chloramine and water in the presence of **calcium** chloride; chlorine dioxide, chlorine peroxide (ClO_2), reddish-yellow gas, melting point —79° C., boiling point 11° C., unpleasant odor, soluble in water and upon cooling chlorine dioxide octahydrate crystallizes, dangerously explosive alone as solid, liquid, gas or with organic matter or phosphorus; reactive with sodium hydroxide solution to form sodium chlorite plus sodium chlorate, and with sodium peroxide to form sodium chlorite plus oxygen gas. Formed by reaction of **potassium** chlorate and concentrated sulfuric acid (Hazard!) and slight warming (chlorine dioxide gas and perchloric acid are formed); chlorine heptoxide (Cl_2O_7), colorless volatile oil, formed by reaction of perchloric acid and phosphorus pentoxide at —10° C., for one day, and then distilling at the boiling point 82° C. of the heptoxide, explosive by percussion or by flame, but unreactive with paper or wood, reactive with water to yield perchloric acid.

Perchlorates: (See **Perchloric Acid.**)

Sulfides: (See **Sulfur,** chlorides.)

Organic Chloro-compounds:

Paraffin and benzenoid **hydrocarbons,** e.g., **ethane** and **benzene,** respectively, react with chlorine by *substitution* of chlorine for hydrogen (hydrogen chloride also formed), e.g., ethane to yield ethyl chloride (C_2H_5Cl) plus further substitution products; benzene, in the presence of a catalyzer, e.g., iodine, phosphorus, iron, to yield chlorobenzene (C_6H_5Cl) plus further substitution products; toluene, under like conditions to benzene, to yield ortho-chlorotoluene and para-chlorotoluene ($CH_3C_6H_4Cl$) plus further substitution products, but, at the boiling temperature, in sunlight, dry, and in the absence of a catalyzer, to yield paraffin-side-chain substitution products, benzyl chloride ($C_6H_5CH_2Cl$), benzal chloride ($C_6H_5CHCl_2$) and benzotrichloride ($C_6H_5CCl_3$).

Olefin, acetylene and benzenoid **hydrocarbons,** e.g., **ethylene, acetylene,** and **benzene,** respectively, react (A) with chlorine by *addition,* e.g., ethylene dichloride ($C_2H_4Cl_2(1,2)$), acetylene tetrachloride ($C_2H_2Cl_4(1,1,2,2)$), benzene hexachloride ($C_6H_6Cl_6$), also carbon monoxide yields carbonyl chloride ($COCl_2$), (B) with hypochlorous acid by *addition* to form, for example, ethylene chlorohydrin (CH_2ClCH_2OH).

Oxygen-function compounds, e.g., **ethyl alcohol, acetaldehyde, acetone, acetic acid,** react (A) with chlorine, to form *chloro-substituted* corresponding or related *compounds,* e.g., ethyl alcohol or acetaldehyde to yield chloral (CCl_3CHO), acetone to yield chloroacetone ($CH_2ClCOCH_3$), acetic acid to yield, at the boiling temperature, dry, and in the absence of a catalyzer, monochloroacetic acid ($CH_2Cl\cdot COOH$), dichloroacetic acid ($CHCl_2COOH$), trichloroacetic acid (CCl_3COOH), the substitution taking place on the alpha-carbon (the carbon next to the carboxyl group (—COOH)), (B) with phosphorus chlorides, to form corresponding *oxygen-function chlorides,* e.g., ethyl chloride (C_2H_5Cl), ethylidene dichloride (CH_3CHCl_2), acetone chloride ($(CH_3)_2CCl_2$), acetyl chloride (CH_3COCl).

Chloroform is made by reaction of **acetone or ethyl alcohol** with calcium or sodium hypochlorite; carbon tetrachloride by reaction of carbon disulfide (CS_2) plus chlorine (Cl_2) in the presence of iron heated (sulfur monochloride, S_2Cl_2, boiling point 139° C., also formed, and separated by fractional distillation); trichloroethylene by reaction of acetylene tetrachloride and dilute alkali. The diazo-reaction (see **Azo- and Related Compounds**) may be used to introduce chlorine into benzenoid compounds.

86. Hexachloroethane	$CCl_3\cdot CCl_3$	187 (sealed tube)	185 (777 mm.)
87. Benzene hexachloride, alpha, trans	$C_6H_6Cl_6$	158	
" " beta, cis	$C_6H_6Cl_6$	297 (decom.)	
88. Hexachlorobenzene	C_6Cl_6	230	309 (742 mm.)

(R.K.S.)

Many of the chloro-compounds are used as reagents or as intermediate compounds in organic chemistry, and as non-inflammable solvent liquids for the extraction of fats and oils, and in cleaning textile materials.

CHLORITE SCHIST. A schist whose color and foliation are chiefly due to the mineral chlorite. Other minerals common in this type of schist are **quartz** and **epidote.** Garnet and **magnetite** sometimes occur as **idiomorphic** crystals giving the schist a **porphyroblastic** texture. (R.M.F.)

CHLORITOID. A mineral which occurs as tabular crystals, probably **triclinic,** foliated masses or scattered scales and plates of a greenish-gray to greenish-black mineral that is characteristic of the less intensely altered **metamorphic** rocks such as **phyllites** and **quartzites.** Chemically it is a hydrous **iron-aluminum silicate. Ottrelite** contains some manganese as well. Chloritoid was originally noted as from the Ural Mountains and named for its greenish color from the Greek word meaning green. Ottrelite was named from Ottrez in Luxemburg. (E.S.C.S.)

CHLOROFORM. Chlorine; **Anaesthesia.**

CHLOROMONADINA. An order of single-celled animals of green color. (See **Mastigophora.**) (A.W.L.)

CHLOROPHYLL. Pyrrole and Related Compounds; Pigments in Plants.

CHLOROPLAST. Pigments in Plants.

CHLOROPLATINIC ACID. Platinum.

CHLOROUS ACID AND CHLORITES. Chlorous acid ($HClO_2$) is a yellow solution, unstable, and of characteristic odor of chlorine dioxide. A strong oxidizing agent.

Formed by the spontaneous decomposition of **chloric acid** into chlorous and **perchloric acids.**

Sodium chlorite is formed (1) by the reaction of chlorine dioxide (ClO_2) and **sodium** hydroxide, with the simultaneous formation of sodium chlorate, and (2) by the reaction of chlorine dioxide and sodium peroxide with accompanying evolution of oxygen gas.

Chlorites are generally yellow. The chlorites of **sodium** and **potassium** are deliquescent, those of **lead, silver, mercurous, mercuric** (red) are insoluble. (R.K.S.)

CHOANOCYTE. The collar cell of **sponges,** bearing a high ridge surrounding a **flagellum** at the free end. They are located in cavities in the sponge and produce currents of water through the passages in the body wall. (A.W.L.)

CHOCOLATE. Theobroma Cacao.

CHOKE COIL. This term is applied to various types of inductances used in electrical circuits primarily to present high reactance at certain frequencies. Such coils usually have high reactance compared to their resistance and offer impedance to the flow of alternating currents by the induced counter electromotive force. Since this **impedance** will vary directly with frequency the choke may be designed to let certain lower frequencies through and stop or impede higher ones. An air-core choke coil is often used in electrical power circuits to block high-frequency transients produced by lightning surges. In communications circuits air-core chokes are used extensively to block radio frequencies from audio-frequency circuits or from d-c parts of the circuit. In these applications they are often called radio-frequency chokes. Iron-cored chokes are frequently used in audio circuits in a similar manner. Iron-cored chokes are also important components of power supply filters as well as many wave **filters.** (L.R.Q.)

CHOLANGITIS. An acute or chronic infection of the **bile** ducts, usually associated with infection of the **gall bladder,** or obstruction of the common duct. While it usually occurs with **cholecystitis** or **cholelithiasis,** rarely it may complicate **pnuemonia, typhoid fever,** or other acute infections.

The symptoms of acute cholangitis are those of an acute cholecystitis with sepsis. **Jaundice** is present due to the obstruction of the common bile duct. **Leukocytosis,** chills, high intermittent fever, colic, vomiting, and severe pain in the abdomen may be present. **Septicemia** may complicate the picture.

Chronic cholangitis is characterized by jaundice, and sometimes by recurring attacks of fever. The degree of jaundice depends on the degree of obstruction.

The treatment in certain cases is surgical drainage of the common bile duct and the gall bladder. (D.M.H.)

CHOLECYSTITIS. Infection of the **gall bladder** occurring in an acute and chronic form. Cholecystitis rarely develops as a primary infection. It is usually secondary to **cholelithiasis,** or is part of a general **cholangitis.**

The **bacterial** organisms usually found in cholecystitis are of the colon-typhoid group. Less frequently the *Streptococcus, Staphylococcus* and *Pneumococcus* are found. The organisms gain access to the organ either by the blood stream or ascend from the **duodenum** through the bile.

The acute form is accompanied by fever, right-sided abdominal pain, vomiting and severe prostration. Jaundice is not seen unless the common bile duct is involved in the acute infection (**cholangitis**). In severe infections of the gall bladder, perforation may occur. This usually results fatally unless surgical intervention is undertaken early.

Chronic cholecystitis is the more common form. It may follow the acute form, or develop insiduously over a period of time. Usually, stones are present in the gall bladder and predispose to infection sooner or later.

The symptoms of chronic cholecystitis are practically the same as those of cholelithiasis. (See **Cholelithiasis.**)

Diagnosis is verified by means of **cholecystography.**

The treatment of cholecystitis is surgical. This is usually done in the chronic stage, and consists of removal of the infected gall bladder. In mild cases, or when operation is contraindicated, a medical regime is followed. (See **Cholelithiasis.**) At times, operation becomes imperative in the acute stage when danger of perforation, or **empyema** of the gall bladder occurs. (R.S.M., D.M.H.)

CHOLECYSTOGRAPHY. X-ray visualization of the **gall bladder.** This procedure is in routine use in diagnosis of gall-bladder disease. It is accomplished by giving the halogen salts of **phthaleins** by mouth, or less often by vein. The salts are excreted by the liver into the **bile** and concentrated in the gall bladder. This renders the gall bladder opaque to x-ray. By this method the position, size, shape and often the presence of stones can be demonstrated. Later a fat meal is given. This causes the gall bladder normally to contract, causing a disappearance or diminution of the shadow on the x-ray plate. When inflammation of the gall bladder or obstruction of the cystic duct is present, the gall-bladder shadow may be absent. (R.S.M., D.M.H.)

CHOLELITHIASIS (GALLSTONES, BILIARY CALCULUS). Gallstones usually form as the result of infection and stasis of **bile.** Changes in the **metabolism** of the body, causing an increase in the **cholesterol** content of the blood or other changes in the composition of the bile have been observed in patients with cholelithiasis, but the significance of these is unknown since

the same changes occur without the formation of stones. In some cases neither infection nor stasis is present and the precipitating factors remain obscure. It is believed by some that in certain cases infection follows stone formation.

Certain predisposing factors are definitely known. The majority of patients are obese, and are usually over 35 or 40 years of age. Females are affected more often than males. Women are prone to cholelithiasis, perhaps because of the increased cholesterol content of the blood during pregnancy. **Typhoid** infection seems to dispose to stone formation.

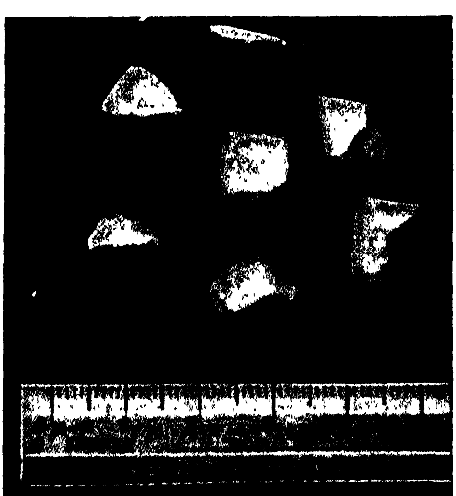
The chemical composition, number, size, and structure of gallstones varies greatly. The largest number reported in one **gall bladder** is said to be 7802. Some stones are very large. In shape, they may be round, irregular or sharply faceted. Solitary stones are often found. Chemically, the stones are commonly of four types: 1. Pure cholesterol. Such stones present, in section, a radiating crystalline structure. 2. Alternate layers of cholesterol and calcium salts. 3. Mixtures of cholesterol and bilirubin-calcium. Such stones are usually soft, noncrystalline, and small in size. 4. Pure bilirubin-calcium.

The symptoms caused by gallstones depend on their position, and the amount of infection (**cholecystitis**) present. The common symptoms seen in most cases are usually vague digestive disturbances, such as dull pains, sour eructation, fullness of the upper abdomen and flatulence. These symptoms are aggravated by eating rich foods, especially those of a fatty nature.

The severe pain or colic that occurs in recurring attacks is due to a stone lodging in the cystic or the common bile duct, to spasm of the gall-bladder walls due to irritation by stones or the infection, or to distention and stretching of the gall bladder by the obstructed bile. If the common bile duct becomes obstructed so that no bile can pass, **jaundice** develops.

The pain accompanying a stone impacted in the system of biliary ducts is often excruciating, and is accompanied by nausea, vomiting and fever—the latter depending on the amount of infection present. The paroxysms of biliary colic tend to recur at more frequent intervals and to become more severe. A large gallstone escaping into the intestine may cause **intestinal obstruction.**

Complications of cholelithiasis are chronic cholecystitis, pancreatitis (inflammation of the **pancreas**), perforation of the gall bladder with resulting **peritonitis**, intestinal obstruction from large gallstones, infection of the **liver** (hepatitis), and adhesion formation around the gall bladder and neighboring organs.



Cholesterin-bilirubin-calcium stones, outer layer pure cholesterin. (*Nelson Loose-Leaf Surgery, Thomas Nelson & Sons.*)

Surgical removal of the gall bladder gives the best results in cholelithiasis. If the patient does not wish or cannot withstand the operation, various medical measures may offer some relief of symptoms. The elimination of fatty and spicy foods and alcohol from the diet, plus the administration of bile salts may help to avoid attacks. Nitroglycerin or amyl nitrite may relieve the muscle spasm during the acute attacks. **Morphine** may be necessary for the relief of colic. (R.S.M., D.M.H.)

CHOLERA. An acute infection involving primarily the terminal portion of the small intestine, the **ileum.** It is a disease of antiquity, and great epidemics have occurred in India, the Orient, Egypt and Europe. Cases have occurred in the eastern part of the United States as well. During the 1879–1883 pandemic, the causative agent was demonstrated to be a small rod, *vibrio cholerae,* which is spread in the same manner as *typhoid* bacilli, i.e., by the intestinal-oral route.

Cholera usually has a sudden onset with profuse **diarrhea,** vomiting, muscular cramps, suppression of urine, **uremia, acidosis,** and collapse. Many of the symptoms are due to extreme dehydration. Death occurs in as high as 50 to 75% of cases. Early treatment with adequate salt and water intravenously, and alkali to prevent acidosis and uremia, reduce the mortality to 25 or 30%. **Penicillin, sulfonamides,** and **antiserum** may have some beneficial effect but this has not been proved. (D.M.H.)

CHOLESTEROL. **Alcohols and Ethers.**

CHONDRI. Rounded and ellipsoidal grains of silicates which are characteristic of meteorites. When viewed in their section the aggregate looks like grains of wheat. (R.M.F.)

CHONDRIOCONT. A structure found within some cells. (A.W.L.)

CHONDRIOSOME. A structure within the cell. (A.W.L.)

CHONDRITE. A term proposed by Rose in 1864 for **meteoric** stones which contain spheroidal aggregates of basic minerals (**pyroxene** and **olivine**), **oligoclase feldspar,** and varying proportion of **nickel-iron.** The percentage of free nickel increases as the percentage of nickel-iron decreases. (R.M.F.)

CHONDROSTEI. The **paddle-fishes** and **sturgeons.** An order with the skeleton made up largely of **cartilage** but with some bony components. (A.W.L.)

CHONOLITH. A term proposed by R. A. Daly in 1905 for irregular **igneous** intrusions which according to their shapes and field relationships cannot be classified as **dikes, laccoliths, batholiths, bysmaliths,** etc. (R.M.F.)

CHORD. The word chord has three well-defined engineering meanings. In railroad and highway practice a chord is a straight line joining the ends of an arc of any given curvature. The sharpness of **circular curves** used on railroad lines is defined by the number of degrees in a central angle subtended by a chord of 100′.

The principal boundary members of the framed **truss** used in bridges or buildings are designated as chord members or chords. Refer to **bridges** for an illustration of chord members.

In aviation terminology, the dimension of an **airfoil** surface parallel to the air stream is called the chord. (F.T.M.)

CHORD, AIRFOIL. The chord is a basic reference axis for the geometric or aerodynamic properties of an **airfoil.** It is normal to the span and lies in the plane

of the airfoil. There are two of these reference chords. The one used for general and structural reference is the *geometric* chord. The other is an *aerodynamic chord,* being an imaginary line through the airfoil parallel to the free air stream at zero lift and passing through the trailing edge. The length of this chord is of no importance. It is useful mainly in aerodynamic studies because the lift varies directly with the **angle of attack** of the aerodynamic chord.

If the airfoil has a flat lower surface an element of this surface is taken as the geometric chord. The chord length is the over-all projection of the profile on this chord. In double-cambered airfoils the geometric chord is taken as the longest straight line possible between leading and trailing edges, or as a straight line joining the ends of the profile median line. The angle of attack to the geometric chord at zero lift is the angle between these chords. This may be discovered by wind tunnel tests, although empirical constructions have been devised which locate the aerodynamic chord surprisingly well. If the wing is tapered there is a tip chord and a root chord. The location of the intermediate chord on which the aerodynamic forces could be assumed to act is of importance in studies of airplane balance and stability. When the coefficient of lift may be assumed to be constant over the semi-span, the mean aerodynamic chord coincides with the mean geometric chord (i.e., the centroid of the semi-wing planform). This simplification is in error if the wing has twist, or if it is rectangular, in which case the uneven downwash causes decreased lift coefficient near the tips. It is an excellent approximation for untwisted tapered wings and exact for untwisted elliptical wings. (F.T.M.)

CHORD, MEAN AERODYNAMIC. Chord, Airfoil.

CHORDATA. The **vertebrates** and a few marine animals of simpler form, including the **tunicates, salpians** and **lancelets.** Although the true vertebrates make up most of this phylum the inclusion of the other forms is scientifically accurate. With these limits the distinctive characters of the phylum are few. The animals are **triploblastic, coelomate,** and **metameric** like the higher invertebrates but differ from them in three points: 1. The skeleton is internal. In its primitive state it consists of a slender longitudinal rod lying above the alimentary tract and called the **notochord.** This structure is present at some stage in development in all of the included species. 2. The **nervous system** is entirely dorsal in position, lying in the body wall above the notochord. 3. The alimentary tract includes a chamber, the **pharynx,** just behind the oral cavity, whose walls are perforated by openings associated with respiration and called the gill slits or pharyngeal clefts. These openings appear or are indicated only in the **embryos** of terrestrial species.

It is difficult to estimate the relative importance of the phylum since man himself is one of the included species. The chordates include the most highly developed animals from the scientific point of view, and from the practical point of view they are equally important as the source of most of our animal foods, furs, feathers, wool, leather, and as beasts of burden. Man has depended on the vertebrates, indeed, for much of his progress, and has taken his domestic animals from this group.

The classification of the phylum is briefly as follows:

Subphylum **Hemichordata.** Worm-like marine animals. **Balanoglossus.** Also named Enteropneusta.

Subphylum **Urochordata.** Sessile or free-swimming forms, marine, with larvae resembling tadpoles in which the characters of the phylum are evident. Also named Tunicata.

- Class **Larvacea.** Small floating animals with the larval form of the subphylum.
- Class **Ascidiacea.** The tunicates. Sessile or free, named from the investing test or tunic which encloses them.
- Class **Thaliacea.** The **salpians.** Free-swimming.

Subphylum **Cephalochordata.** The lancelets. Small fish-like animals which swim freely and also burrow in the sand.

Subphylum **Vertebrata.** The skeleton includes cartilaginous or bony components in addition to the notochord. Also named Craniata.

- Class **Cyclostomata.** The round-mouthed **eels:** lampreys and hags.
- Class **Pisces.** The fishes. Sometimes placed in two classes: Elasmobranchii, containing the **sharks, rays,** etc., and Pisces, containing the remaining fishes.
- Class **Amphibia.** The **salamanders, frogs, toads,** etc.
- Class **Reptilia.** The **lizards, snakes, turtles, crocodiles,** etc.
- Class **Aves.** The birds.
- Class **Mammalia.** Popularly called animals without further qualification. They secrete milk for the nourishment of their young and the skin usually bears some hair, often a complete coat which may be in the form of fur or wool. Mice (**mouse**), **horses** and **cattle, monkeys,** man, and many other forms. (A.W.L.)

CHORDOTONAL ORGAN. An organ for the perception of vibrations, found in the insects where it may exist singly or in association with complex auditory organs. It consists of a nerve ending with accessory cells connected directly to the body wall or to some modified derivative of the body wall in an organ of hearing. (A.W.L.)

CHOREA (St. Vitus' Dance. Sydenham's Chorea). Acute chorea is an affection of the central nervous system characterized by involuntary writhing movements and coarse muscular twitchings. It occurs primarily in children, girls more often than boys, and is frequently associated with acute **rheumatic fever.** The cause is obscure; in some respects chorea behaves as an infection, but no bacterial or virus agent has ever been isolated in the disease. It runs a course of weeks or months and may recur. Treatment is rest and sedation. (D.M.H.)

CHORION. 1. An accessory structure formed during embryonic development in **mammals.** It provides the connection with the tissues of the mother through which all interchange of materials between her blood and that of the **embryo** is carried on prior to birth.

The chorion is a composite structure formed of the **serosa** and the **allantois,** although the name is sometimes erroneously applied to the serosa alone. In some mammals a specialized **placenta** develops from part of the chorion as the persistent connection with the mother. Like all other extraembryonic membranes, this structure is discarded at birth.

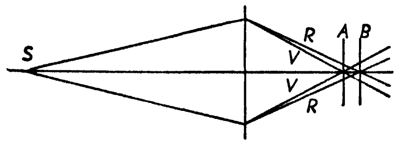
2. The shell of an insect egg. (A.W.L.)

CHOROLOGY. Zoogeography.

CHOUGH. Aves, Passeriformes. *Pyrrhocorax.* Eurasian birds (**Aves**) related to the crows and resembling them in form and color. A few other Asian birds are known as chough-thrushes. (A.W.L.)

CHROMATIC ABERRATION. The indistinct color effects observed along the edges of images formed by a simple **lens** constitute what is known as the chromatic aberration of the lens. This aberration is due to the fact that the glass, or any other substance, out of which the lens is constructed produces **dispersion** (i.e., re-

fracts light of different colors by different amounts). In a convergent glass lens the focal length is greater for red light than for blue, while in a divergent (concave surface) glass lens the blue focus is longer than the red. The effect for the convergent (convex surface) lens is shown, highly exaggerated, in the figure, in which the location of the image of a source, S, is shown for red



Chromatic aberration.

light, R, to be in the plane, B, and for blue light, V, to be in the plane, A. An observer using an **eyepiece** focused for the plane A will see a sharp image of the source in blue light surrounded by the margin of a confused set of images of greater size in other colors.

Chromatic aberration is very bothersome to users of lenses either for telescopic, microscopic, or photographic purposes and ever since optical instruments came into use attempts have been made to design "achromatic" lenses. For relatively short focus instruments, such as **cameras** or field glasses, practically complete achromatism can be obtained by using, instead of a simple convex lens, a combination of a convex and a concave lens, the two lenses being constructed of glasses of different dispersive powers. Prospective purchasers of field glasses, opera glasses or binoculars should always examine them carefully to determine whether or not the lenses are properly achromatized. A simple test is to examine the edge of a white building, which is in full sunlight, through the instrument under consideration. Move the image of the edge well over to one side of the field of view, and, if the lenses are properly figured, no color effects will appear. If, however, chromatic aberration is present, the image of the edge of the white building will be found to be bordered with a bright-colored fringe which increases in width as the image is moved closer to the edge of the field. In passing it might be said that the same test will indicate whether or not the field glasses are properly corrected for **spherical aberration** and other aberrations, for in a poor lens the image of the edge will become blurred and curved when moved to the side of the field of view.

In long focus instruments, such as astronomical **telescopes**, complete achromatism is virtually impossible. Partial achromatism may be obtained in such instruments by employing the combination of the divergent and convergent lenses of glass of different dispersive powers. (See **Dispersion.**) Two types of partial achromatism are employed, depending upon the purposes for which the telescope is designed. In a telescope to be used for photographic purposes the colors which are most active photographically, i.e., the greens and blues, are all brought to the same focal point, whereas the reds and oranges are thrown well out of this focal plane.

In a so-called visual telescope the yellowish-green light is all brought to one sharp focus, while the blues and violets are bent well inside this visual focus. On looking at the image of a very bright object, such as the **moon**, a **planet**, or a bright **star**, a halo of bluish light can be observed due to the out of focus photographic light, but this halo is so diffuse that it is not objectionable when working with objects of the brilliance for which the instrument is designed. Instruments designed for visual observing (visual refractors) cannot be used satisfactorily for celestial photography without employing yellow sensitive plates and color filters to eliminate the out of focus blue and green light.

The image formed by a concave metal or silver on glass mirror is free from chromatic aberration since all colors are reflected in the same direction. This is the most important optical advantage of the reflecting telescope over the refracting type. (W.K.G.)

CHROMATIN. A substance found in the **nucleus** of the **cell**, named for its pronounced affinity for biological stains. It is the bearer of **hereditary** qualities of the organism. It usually occurs in the form of small granules distributed throughout the nucleus. When the nucleus is about to divide the chromatin particles mass together to form the **chromosomes.**

Chromatin of special qualities has received special names in several cases. Basichromatin takes basic stains, oxychromatin, acid stains. Trophochromatin governs the vegetative activities of the cell and idiochromatin its reproductive functions. (A.W.L., R.M.W.)

CHROMATOPHORE. The chromatophore, also called a chromoplastid, is a definite body occurring in the **protoplast.** It is characteristic of a chromatophore that it should have a definite color, due to the pigment or **pigments** present in it.

In plants the most common chromatophore is the **chloroplastid.** Other chromatophores are of various colors, including yellow, brown, orange, and red. Not all plant pigments are found in chromatophores, however. Many occur dissolved in the cell sap.

Chromatophores found in the skin of animals of several groups, including **arthropods, mollusks,** and **vertebrates,** are large cells, often extensively branched. They are well developed in the **octopus** and **squid,** in many **amphibians** and fishes, and in **reptiles.**

Rapid changes in color such as those of squids and some lizards have been ascribed to a contraction of the chromatophores but it now seems evident that the cell itself does not contract although the pigment within it may undergo a considerable change in distribution, revealing itself when widely distributed and otherwise concealed from view. (R.M.W., A.W.L.)

CHROMIDIA. Granules in the cytoplasm of **cells** which stain deeply with basic stains and are derived from the nucleus. In some cells they constitute a nucleus of scattered parts, as in **bacteria.** (A.W.L.)

CHROMIOLE. A granule within a **chromomere.** (A.W.L.)

CHROMITE. An important mineral in the chromite series of multiple oxides. The dominant compound is $FeCr_2O_4$, but most chromite also contains magnesium (Mg) and aluminum (Al). Crystallizes in the isometric system. Hardness, 5.5; specific gravity, 4 5–4.8; color, black. Associated with **periclotite** and **serpentine** (metamorphised peridotite). Chromium (Cr) is a highly important metal in the making of steels which are particularly resistant to rust and heat. It is also used in decorative and wear-resisting plating; the manufacture of refractories, such as furnace brick and cement; and in the manufacture of chemicals used in dyeing, tanning, and pigment industries. Commercial amounts occur as placer deposits in serpentine areas. In the United States chromite has been mined in Maryland, Pennsylvania, California, Montana, Oregon, Wyoming and North Carolina. Important deposits occur in Quebec, Canada. Valuable deposits occur in Asia Minor, Southern Rhodesia, New Caledonia, Cuba, India, and the Philippines. Also in New South Wales, and in the Urals associated with platinum. (R.M.F.)

CHROMIUM. Symbol: Cr. Atomic number: 24. Atomic weight: 52.01. Density: 7.1. Hardness: 9. Melting point: 1615° C. Boiling point: 2200° C.

Chromium is a slightly grayish metal, hard, and capable of taking a brilliant polish; not appreciably ductile or malleable; soluble in **hydrochloric** or **sulfuric acid** (dilute); made passive by **nitric acid** (di-

lute or concentrated) or sulfuric acid (concentrated); not affected by air or water at ordinary temperatures; not affected by fused alkalis; when heated to 200° C. in air forms chromic oxide. Discovered by Vauquelin in 1798. (**Isotopes**: page 290.)

Chromium metal is used (1) in special steels—less than 1% Cr in chrome or nickel-chrome steels greatly increases the hardness, (2) in corrosion resistant or "stainless" steels—8%–14% Cr, (3) in electroplating, as a protective and ornamental coating for less resistant metals—electrodeposited chromium is the hardest form of the metal, being almost as hard as diamond, and very resistant to corrosion, but the very thin layers deposited electrolytically may be easily damaged due to the relative softness of some supporting metals, (4) in special alloys, e.g., wire of high electrical resistance for heating units, nichrome or chromel wire (11%–25% Cr, 50% or more nickel, remainder iron).

Chromium occurs chiefly as chromite (ferrous **chromite**, $Fe(CrO_2)_2$) in southern Rhodesia, Union of South Africa, U.S.S.R., New Caledonia, India, Philippine Islands, Japan, Turkey, Greece, Cuba, and California. (1) Heating chromite in the **electric furnace** with **carbon** yields ferrochrome for alloys, and (2) when chromite is heated with **sodium** carbonate and nitrate, **sodium** chromate is formed, which is then extracted with water. This is the substance from which chromium compounds are obtained.

Acetates: Chromous acetate ($Cr(C_2H_3O_2)_2$), brownish-violet solid; chromic acetate ($Cr(C_2H_3O_2)_3 \cdot H_2O$), grayish-green solid. Both are soluble and used as mordants in dyeing and printing textiles, and in tanning.

Alum: See Sulfate below.

Chlorides: Chromous chloride ($CrCl_2$), white solid, by heating chromic chloride in dry **hydrogen** gas, and obtained as a blue solution by reduction of chromic chloride solution with **zinc** metal, or by reaction of chromium metal and **hydrochloric acid** in the absence of air; chromic chloride ($CrCl_3$), exists in two forms, (1) green, deliquescent crystals, soluble in water, formed by reaction of chromium hydroxide and hydrochloric acid and subsequent crystallization, (2) reddish-violet crystals, anhydrous, insoluble in water or dilute or concentrated acids, although the presence of a very small amount of chromous or stannous chloride renders the chromic chloride soluble, formed by heating chromic oxide in sulfur chloride above 400° C. Solutions of chromic chloride, concentrated or acidified, are green, when diluted violet; chromyl chloride (CrO_2Cl_2), red liquid, boiling point 118° C., by heating anhydrous sodium or potassium dichromate with sodium chloride and concentrated sulfuric acid.

Chromates and dichromates: **Sodium** chromate (Na_2CrO_4), **potassium** chromate (K_2CrO_4), **ammonium** chromate ($(NH_4)_2CrO_4$), **calcium** chromate ($CaCrO_4$), are yellow soluble solids; **barium** chromate ($BaCrO_4$), pale yellow, **strontium** chromate ($SrCrO_4$), pale yellow, **lead** chromate ($PbCrO_4$), yellow (used as a pigment, "chrome yellow"), **zinc** chromate ($ZnCrO_4$), yellow, used as a pigment, **mercurous** chromate (Hg_2CrO_4), yellow to red to brown, **silver** chromate (Ag_2CrO_4), reddish-brown, are insoluble solids. **Sodium** dichromate ($Na_2Cr_2O_7$), **potassium** dichromate ($K_2Cr_2O_7$), readily crystallized, ammonium dichromate ($(NH_4)_2Cr_2O_7$) (forming nitrogen gas and green chromic oxide solid upon heating), are red soluble solids, of important application as oxidizing agents, e.g., sulfurous acid causes reduction to chromic; silver dichromate ($Ag_2Cr_2O_7$), red insoluble solid, changing to silver chromate (Ag_2CrO_4) upon boiling with water. Solutions of chromate in the presence of acid are changed to the corresponding dichromate.

Dichromates: See Chromates. Solutions of dichromate in the presence of alkali are changed to the corresponding chromate.

Hydroxides: Chromous hydroxide ($Cr(OH)_2$), brown precipitate, formed by reaction of chromous salt solution with **sodium** hydroxide solution; chromic hydroxide ($Cr(OH)_3$), grayish-green precipitate, formed by reaction of chromic salt solution with sodium or ammonium hydroxide or sulfide solution, soluble in excess of sodium hydroxide but reprecipitated upon boiling, soluble in acids.

Oxides: Chromic oxide, chromium sesquioxide (Cr_2O_3), green solid relatively insoluble in acids after having been heated to 500° C., a good **refractory** material, formed by ignition of ammonium dichromate or chromium hydroxide, reduced to chromium metal (1) by heating

REPRESENTATIVE ALLOYS CONTAINING CHROMIUM

25–30% Cr		75–70% Fe	Resistant to oxidation at high temperature and to nitric acid. Not very ductile.
25% Cr	12% Ni	63% Fe	Tougher than "18–8" below. Heat resistant up to 1150° C. High resistance to oxidation.
20% Cr	67% Ni with C, Si, Mn approximately 1% each		Heat resistant up to 1200° C. Electrical resistance wire for heating.
18% Cr	8% Ni	74% Fe	"18–8" for castings, hot and cold-rolled bars, forgings, cold-drawn bars, plates, sheets, tubes, strips, and wire. For chemical apparatus. Especially resistant to dilute and concentrated nitric acid, and to sodium hydroxide (up to 20% NaOH); refrigeration equipment; furnace parts.
16–20% Cr		84–80% Fe	For castings, forgings, hot-rolled sheets, bars, plates, strips, and tubes. Heat-resistant up to 870° C. Resistant to ammonia and to nitric acid.
12–16% Cr		88–84% Fe	(a) with C maximum 0.10%, as "Stainless iron" for moderately corrosive conditions. (b) with C 0.1 to 0.3%, as "Cutlery stainless iron," more resistant to corrosion than (a). (c) with C 1 to 2%, as "Die stainless iron," resistant to abrasion, but less resistant to corrosion than (a) or (b).

(R.K.S.)

with carbon in the electric furnace, or (2) by ignition with **aluminum** powder; chromium trioxide, chromic anhydride, "chromic acid" (CrO_3), brownish-red crystals, soluble in water forming chromic acid (H_2CrO_4 or $H_2Cr_2O_7$), formed by addition of concentrated **sulfuric acid** to dichromate solution, forms chromic oxide and oxygen upon being heated to 190° C., a powerful oxidizing agent in which reaction chromic compound is formed. Used as a mordant in dyeing wool and silk.

Sulfate: Chromium sulfate, chromic sulfate ($Cr_2(SO_4)_3 \cdot 18H_2O$), violet crystals, formed by reduction of dichromate with sulfurous acid in sulfuric acid solution, and crystallization. Used as a mordant in the textile industry, in the photographic fixing bath, in tanning, and in ceramics; chromium potassium sulfate, "chrome alum" ($Cr_2(SO_4)_3 \cdot K_2SO_4 \cdot 24H_2O$). Used as chromium sulfate.

Sulfide: Chromium sulfide (Cr_2S_3), brownish-black powder, formed by heating chromium metal in **carbon disulfide** vapor, not formed by wet methods because with water forms chromium hydroxide plus hydrogen sulfide.

Chromic acid and chromates are detected by the formation with lead acetate solution of a yellow precipitate (lead chromate) soluble in nitric acid, but insoluble in acetic acid.

For the detection of chromous and chromic compounds see **Analytical Chemistry.** (R.K.S.)

CHROMIZING. Production of a high chromium content surface layer on iron and steel by heating at high temperatures in a solid packing material containing chromium powder, or in an atmosphere containing chromium chloride. The surface layer is formed by diffusion of chromium into the iron in the same manner as carbon diffuses into iron in **carburizing;** however, the process is much slower and requires higher temperatures than carburizing. A similar result can be obtained by high-temperature diffusion of electrodeposited chromium. Chromized coatings have corrosion resistance and elevated temperature oxidation resistance similar to the high chromium types of **stainless steels.** The principal use of chromizing has been in Europe. (R.H.H.)

CHROMOGENIC COUPLERS. Couplers are used in secondary color development. (See **Color Development.**) The term "coupler" is applied to a large number of organic compounds which combine with a limited number of chromogenic developers to produce dye images with a wide range of color and intensity. Couplers are dye intermediates but differ from chromogenic developing agents in that they do not as a rule have the ability to develop a silver image.

Couplers may be hydroxy or amine derivatives of aromatic groups, as benzene, naphthalene or anthracene. Phenol, naphthol, analine, cresol, para-aminophenol and dimethylparaphenylenediamine are examples. With these compounds coupling takes place with the hydrogen atom which is in the ortho or para position to the hydroxy or amino group on the coupler.

Compounds having active methine ($=CH_2$) groups, with strong polar groups for other valences as the cyano ($-CN$), the carborryl ($-CO$), the aceto (CH_3CO-), the acid ester ($-COOC_2H_5$), and the phenyl, ($-C_6H_5$) groups will couple. Acetoaceticester and paranitrophenylacetonitrile are illustrations.

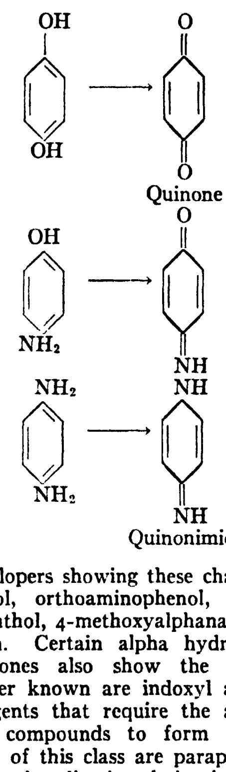
The methine group may be part of a ring structure as in coumarine and indoxyl, or may be part of a heterocyclic ring attached to a phenyl group as in 1-phenyl-3 methyl-5 pyrazolone.

Compounds having a N in the ring will couple if there is a methyl ($-CH_3$) group, attached to the ring in the alpha position to the nitrogen. Two illustrations for this type are picoline and 2-methyl-thiazole.

Because secondary color development has been particularly successful in the development of color materials, and because of the ease by which it is possible to control color by this method, the field of couplers has expanded rapidly. (See **Chromogenic Developing Agents** and **Color Development.**) (S.M.T.)

CHROMOGENIC DEVELOPING AGENTS. Chromogenic developing agents are selective organic reducers which not only have the ability to reduce exposed silver halide but also become dye intermediates by oxidation during the developing process. Color results when the oxidized developing agent, or product from reduction, unites, condenses, or couples with a molecule of the unoxidized developing agent or with another organic compound, known as a coupler, to form a dye.

Developing agents capable of forming dyes by addition, or condensation with the oxidized product, are known as *class 1* developers. Examples of these developers are para and ortho derivatives of dihydroxy, diamino, and hydroxy and amino benzene, or naphthalene. It is believed that the reaction is possible because these developers are readily oxidized to quinone and quinonimid structures, as



Quinone

Quinonimid

Among the developers showing these characteristics are: para-aminophenol, orthoaminophenol, catechol, pyrogallol, alphanaphthol, 4-methoxyalphanaphthol, and hydroxycoerulignon. Certain alpha hydroxyketones and alpha aminoketones also show the same property. Among the better known are indoxyl and thioindoxyl.

Developing agents that require the addition of dissimilar organic compounds to form dyes belong to *class 2.* Typical of this class are paraphenylenediamine and the paraphenylenediamine derivatives in which the hydrogens of one of the amine groups are mono- or disubstituted. Dimethylparaphenylenediamine, diethylparaphenylenediamine and 2-amino-5-diethylaminotoluene are excellent developers in this class. In a number of instances the N of the amine group may be a part of the heterocyclic ring structure as: 6-amino-N-methylpenomorphine, 4-hydroxy-isocarbstyril, and 1-phenyl-3 methyl-4 amino-5-pyrazolone.

Leuco derivatives of certain vat dyes can be prepared in stable form. These act as developers in alkaline solution forming insoluble colored compounds on oxidation. Indigo white, a leuco base, is an example. (See **Chromogenic Couplers; Color Development.**) (S.M.T.)

CHROMOMERE. One of the masses into which the chromosome is differentiated longitudinally. (See **Cell.**) (A.W.L.)

CHROMONEMA. A thread of **chromatin** in the resting cell. (A.W.L.)

CHROMOPHORE. **Dyes.**

CHROMOSOME. A unit into which the **chromatin** of the cell forms during **cell division.** Important in **heredity.** (A.W.L.)

CHROMOSOME NUMBER, PLOIDY. Chromosome number is of importance in **heredity** and **taxonomy.** Each species has a characteristic, though not necessarily different, chromosome number. The term ploidy is applied to the number of chromosomes, and other terms derived from it are used to designate modifications in the characteristic number as they normally occur during reproduction or as they are artificially produced. The body cells in each species have two complete sets of chromosomes in each nucleus. One set constitutes the haploid complement, the two sets the diploid complement. Chromosomes occur in pairs, the haploid or monoploid set consisting of one member of each pair found in the diploid nucleus. The diploid number is reduced to the haploid number by **meiosis,** restored by **fertilization,** and maintained as a constant number in every cell of the body by mitosis during **cell division.** In man, for instance, the diploid number is 48; eggs and sperm produced by meiosis have the haploid number 24, and the fertilized egg two sets of 24 each, one set contributed by each parent. Two of the chromosomes in the female, in man and certain other animals, are called allosomes or x-chromosomes and are concerned with sex determination, the male having only one allosome paired with a y-chromosome which has nothing to do with sex and is missing in many species. Chromosomes other than allosomes are called autosomes.

Further variation in chromosome number is common in plants, although less common in animals, and may be induced experimentally. Even haploid plants have been found, proving that the haploid set constitutes the basic, irreducible complement of each species. Variation may take the form of simple multiplication of the haploid number, a condition known as euploidy (true ploidy). If N is taken as the haploid number, $2n$ would be diploid, $3n$ triploid, $4n$ tetraploid, $5n$ pentaploid, $6n$ hexaploid, $7n$ heptaploid, $8n$ octoploid, $9n$ enneaploid, and $10n$ decaploid. Multiples above $10n$ are referred to as 11-ploid, 12-ploid and so on. The tetraploid number is common among cultivated plants. This and other multiples have been induced by the use of **colchicine** which prevents the consummation of normal mitosis or meiosis and doubles the diploid number. Even-numbered euploids breed true, the gametes of a tetraploid, for example, being diploid. Odd-numbered euploids often give rise to aneuploid plants having numbers such as $2n + 1$, $2n + 2$, etc. The trisomic condition, $2n + 1$, has been of use in the identification of the hereditary effect of whole chromosomes, one at a time, since the extra chromosome is an extra member of a pair. In the Jamestown Weed, **Datura,** which has 24 chromosomes, all possible primary trisomics, 12, have been induced and studied in detail. The various types mentioned in this paragraph are called collectively autoploids.

Another type of variation is induced when species are crossed with one another. These contain two different haploid complements; no chromosome finds a homologous chromosomes with which to pair at meiosis with the consequence that spore formation and consequently gamete formation are interfered with and species hybrids are usually sterile. Even before colchicine and other treatments had been used to double the chromosome number of the species hybrid and so make normal reproduction possible, amphidiploids (double diploids) had been found. The classic example is the cross between the radish (18 chromosomes) and the cabbage (18 chromosomes). The hybrid had 9 radish chromosomes and 9 cabbage chromosomes and was almost completely sterile. A few seeds were found one of which gave rise to a true-breeding hybrid which had 18 radish and 18 cabbage chromosomes. This is the amphidiploid condition and the plant produces gametes with the original haploid complement of each of the parent species. It is now possible to double the chromosome number of sterile hybrids thus producing amphidiploids almost at will. A very powerful tool for the production of entirely new varieties of plants is thereby made available. The phenomenon may also explain the origin of certain species. Ploidy of this type is known as alloploidy. (P.A.W.)

CHROMOSPHERE. The chromosphere is the layer of **atmosphere** of the sun which is composed principally of hydrogen, helium and calcium. It lies at a distance of several hundred miles above the **photosphere** and merges into the **reversing layer** below and the **corona** above. Since the elements which compose the chromosphere contain strong spectral lines in the red, it is usually visible at a total **eclipse** of the sun as a brilliant red envelope about the sun, and gets its name from this fact The chromosphere may be observed with specially designed instruments, similar to those used in the study of **prominences,** even without a total eclipse. (W.K G.)

CHRONOGRAPH. As the word itself implies, a chronograph is an instrument for writing time. In the usual type of instrument a drum carrying a sheet of paper is rotated by clockwork at the rate of 1 rpm. A pen, attached to the armature of an electromagnet, is carried parallel to the axis of the drum by a screw and rests on the paper, tracing a spiral line. The electromagnet is connected in an electric circuit with a standard clock in such a manner that every second the pen makes a short lateral movement which graduates the spiral line into seconds. A key is connected in the circuit in such a manner that each time the key is closed an extra graduation is made on the spiral. When the sheet is removed from the drum a scale may be used to measure the distance of the marks made by pressing the key from the marks made by the clock. In this way the time of pressing the key may be readily measured to 0.01 of a second. Where observation times are required with greater accuracy, the drum may be rotated more rapidly and a tuning fork used to make the time graduations. Other types of chronograph use a steadily moving strip of paper on which the pen traces its record. On the printing type of instrument a set of type wheels is rotated by a standard clock and each time a key is pressed a piece of paper is pressed against the type and the instant printed to the nearest hundredth of a second. Chronographs have many uses, for example, in apparatus designed to record vibrations from **earthquakes.** (W.K.G.)

CHRONOLOGY. The study of the measurement of time. This term is used by the geologist to include the methods employed in determining the age of the earth, and also the sequence of events. The principal methods that are employed are: 1. **Salinity** of the oceans. Assuming that the oceans were originally fresh water and that their present saltiness is due to river-borne solutions, it is computed that the oceans are from 90–600 million years old. 2. **Erosion.** It has been estimated that, to produce a major **unconformity,** having an approximate area of 3 million sq. miles, would take 9 million years. Therefore the unconformity (plane of erosion) which forms the boundary between the Archeozoic and the Proterozoic is a fundamental factor in the computation of **pre-Cambrian** time alone. 3. **Deposition.** The rate of deposition or time which it has taken to produce the

stratigraphic sequence of sedimentary formations may be taken as a measure of the age of the earth. It is estimated that the post-**Proterozoic** stratigraphic column is approximately 350,000'. If this amount of sediment was the result of continuous depositions, at the present rate of deposition for the Nile delta, it would intimate that the earth was only 12 million years old. (Compare with "radioactive methods.") 4. **Radioactive** elements. The study of the radioactive minerals offers a method of determining the time at which the minerals crystallized from the **magma.** Since igneous rocks intrude sedimentary **formations** which may be dated by **stratigraphic** methods, it is possible to date both the intrusive and the intruded sedimentary rocks in terms of the appropriate period of the **geologic time-scale.** According to the radioactive method the oldest known rocks were formed approximately 1800 million years ago. (R.M.F.)

CHRONOMETER. For many types of field observing where accurate time is required, the use of the pendulum clock is not practicable. This is particularly true on shipboard or in countries like Japan, where earthquakes frequently disturb the pendulum. The chronometer is an accurate type of escapement timekeeper which is spring driven. The movement is similar to that in the ordinary pocket watch but much more massive. Various devices to compensate for changes in temperature and for changes in the tension of the spring are incorporated in the instrument. When properly handled, the rate of a chronometer may be relied upon to within a few hundredths of a second per day. With modern methods of obtaining clock comparisons by radio at frequent intervals, the chronometer may be used for all except the most refined astronomical observations. Many chronometers are equipped with devices for making or breaking an electric circuit so that they may be used in conjunction with the **chronograph.** (W.K.G.)

CHRYSALIS, CHRYSALID. The third stage in the development of **butterflies,** also properly called the pupa The caterpillar of a butterfly spins no cocoon but hangs itself by a silken button or by a belt and button. The skin of the pupa into which it changes is often brightly colored or protectively colored and marked, unlike the mahogany-colored pupae of most moths. Although some moths form similar naked pupae the term chrysalis is applied only to those of the butterflies. (A.W.L.)

CHRYSOBERYL. (CYMOPHANE — GOLDEN BERYL). The mineral chrysoberyl, an **aluminate** of **beryllium** corresponds to the formula $BeAl_2O_4$, crystallizes in the **orthorhombic** system with both contact and penetration twins common, often repeated resulting in rosetted structures. Hardness 8.5; specific gravity, 3.5–3.84; luster vitreous; color various shades of green, sometimes yellow. A variety which is red by transmitted light is known as **alexandrite.** Streak colorless; transparent to translucent, occasionally opalescent.

Chrysoberyl occurs in granitic rocks, **pegmatites** and mica **schists;** often is found in alluvial deposits. The Ural Mountains yield **alexandrite;** other localities for chrysoberyl are Czechoslovakia; Ceylon; Southern Rhodesia; Brazil and Madagascar where it occurs of gem quality in the pegmatites of that island. In the United States it is found in Maine, Connecticut and New York. The word chrysoberyl is derived from the Greek words meaning golden, and beryl. **Cymophane** has its derivation also from the Greek words meaning wave, and appearance, in reference to the opalescence exhibited at times. (E.S.C.S.)

CHRYSOCOLLA. This mineral, a hydrous **silicate** of **copper** probably corresponding to the formula $CuSiO_3 \cdot 2H_2O$, is perhaps a mineral gel for it usually appears as an amorphous mass, in veins, or as incrustations. It is very rarely found in small acicular crystals which are either **hexagonal** or **tetragonal.**

Its color is generally some shade of blue or green but if impure may be brown or black. It has a characteristic conchoidal fracture; hardness, 2–4; specific gravity, 2–2.2; vitreous to dull luster; translucent to opaque.
